It is a peculiarity of the white ivy to throw out arms from the middle of the leaves, with which it invariably embraces any object that may be on either side of it; this is the case, too, with walls, even though it should not be able to clasp them. If the trunk is cut across in ever so many places, it will still live and thrive, having as many fresh roots as it has arms, by means of which it ensures safety and impunity, while at the same time it sucks and strangles the trees to which it clings. There are great differences also in the fruit of both the white ivy and the black; for in some of them the berry is so bitter that birds will not touch it. There is an ivy also which grows upright, and stands without any support; being the only one that does so among all the varieties, it has thence obtained the distinctive name of “cissos.” The chamæcissos, on the other hand, is never found except creeping upon the ground.

CHAP. 63. (35.)

THE SMILAX.

Very similar to the ivy is a plant which first came from Cilicia, but is now more commonly found in Greece, and known by the name of smilax. It has numerous thick stalks covered with joints, and thorny branches of a shrub-like form: the leaf resembles that of the ivy, but is not angular, while from the foot-stalk it throws out tendrils; the flower is white, and has the smell of the lily. It bears clusters like those of the wild vine and not the ivy, and of a reddish colour. The larger berries contain three stones, the smaller but one only: these berries are black and hard. This plant is looked upon as ill-omened, and is consequently banished from all sacred rites, and is allowed to form no part of chaplets; having received this mournful character from the maiden Smilax, who upon her love being slighted by the youth Crocus, was transformed into this shrub. The common people, being mostly ignorant of this, not unfrequently take it for ivy, and pollute their festivities with its presence; for who, in fact, is unaware that the ivy is used as a chaplet by poets, as also by Father Liber and Silenus? Tablets are made of the wood of the smilax, and it is a peculiarity of this wood to give out a slight sound, if held close to the ear. It is said that ivy is remarkably efficacious for testing wine, and that a vessel made of this wood will let the wine pass through it, while the water will remain behind, if there has been any mixed with it.

CHAP. 64. (36.)

WATER PLANTS: THE RUSH: TWENTY-EIGHT VARIETIES OF THE REED.

Among those plants which thrive best in cold localities, it will be only proper to mention the aquatic shrubs. In the first rank, we find the reed, equally indispensable for the emergencies of war and peace, and used among the appliances of luxury even. The northern nations make use of reeds for roofing their houses, and the stout thatch thus formed will last for centuries even; in other countries, too, they make light vaulted ceilings with them. Reeds are employed, too, for writing upon paper, those of Egypt more particularly, which have a close affinity to the papyrus: the most esteemed, however, are the reeds of Cnidos, and those which grow in Asia, on the margin of the Anaitic Lake there.

The reed of our country is naturally of a more fungous nature, being formed of a spongy cartilage, which is hollow within, and covered by a thin, dry, woody coat without; it easily breaks into splinters, which are remarkably sharp at the edge. In other respects, it is of a thin, graceful shape, articulated with joints, and tapering gradually towards the top, which ends in a thick, hairy tuft. This tuft is not without its uses, as it is employed for filling the beds used in taverns, in place of feathers; or else, when it has assumed a more ligneous consistency, it is pounded, as we see done among the Belgæ, and inserted between the joints of ships, to close the seams, a thing that it does most effectually, being more tenacious than glue, and adhering more firmly than pitch.

Detailed table of contents

CHAP. 65.

REEDS USED FOR ARROWS, AND FOR THE PURPOSE OF WRITING.

It is by the aid of the reed that the nations of the East decide their wars; fixing in it a barbed point, they inflict a wound from which the arrow cannot be withdrawn. By the addition of feathers they accelerate the flight of this instrument of death, and the weapon, if it breaks in the wound, furnishes the combatants with a weapon afresh. With these missiles the warriors darken the very rays of the sun. It is for this reason more particularly that they desire a clear and serene sky, and hold in abhorrence all windy and rainy weather, which has the effect of compelling them, in spite of themselves, to be at peace with one another.

If a person were carefully to enumerate the peoples of Æthiopia, Egypt, Arabia, India, Scythia, Bactria, and Sarmatia, together with all the numerous peoples of the East, and the vast realms of the Parthians, he would find that fully one-half of mankind throughout the whole world live under a dominion imposed by the agency of the arrow. It was their surpassing excellence in this arm that so ennobled the warriors of Crete, though in this respect, as well as in all others, Italy has gained the mastery; there being no reed in existence better adapted for making arrows than that found in the Rhénus, a river of the territory of Bononia: filled with a greater quantity of pith than any of the others, it is light, and easily cleaves the air, while at the same time it has sufficient weight to resist the action of the wind; an advantage that is not possessed in an equal degree by those employed among the Belgæ. These advantages, however, are possessed by the most approved kinds that are found in Crete, although those of India are preferred; in the opinion of some persons, however, these last are of a totally different nature, for by adding a point to them, the natives are able to use them as lances even. Indeed, we find that in India the reed grows to the thickness of a tree, a fact which is proved by the specimens which are everywhere to be seen in our temples. The Indians assure us that in this plant, too, there is the distinction of male and female; the body of the male being more compact, and that of the female of a larger size. In addition to this, if we can credit the fact, a single compartment between the joints is sufficiently large to answer the purposes of a boat. These reeds are found more particularly on the banks of the river Acesines.

In every variety of the reed a single root gives birth to numerous stems, and if cut down, they will shoot again with increased fecundity. The root, which is naturally tenacious of life, is also jointed as well as the stem. The reeds of India are the only ones in which the leaves are short; but in all the varieties these leaves take their rise at the joints, and surround the stem with a fine tissue about half way upwards to the next joint, and then leave the stem and droop downwards. The reed, as well as the calamus, although rounded, has

two sides, which throw out leaves alternately from above the joints, in such a way that when one springs from the right side, the next issues from the joint above it on the left, and so in turns. Branches, too, shoot occasionally from the stem, being themselves reeds of diminutive growth.

Detailed table of contents

CHAP. 60.

FLUTE REEDS: TET REED OF ORCHOMENUS; REEDS USED FOR FOWLING AND FISHING.

The varieties of the reed are numerous. Some are more compact than others, thicker at the joints, and with a shorter interval between them; while others, again, are less compact, with longer intervals between the joints, and not so straight. Another kind of reed is quite hollow; it is known as the "syringia," and is particularly useful for making flutes, having neither pith in it nor any fleshy substance. The reed of Orchomenus has a passage in it open from one end to the other, and is known as the auleticon; this last is best for making pipes, the former for the syrinx. There is another reed, the wood of which is thicker, and the passage very contracted, being entirely filled with a spongy kind of pith. One kind, again, is shorter, and another longer, the one thinner, the other more thick. That known as the donax, throws out the most shoots, and grows only in watery localities; indeed, this is a point which constitutes a very considerable difference, those reeds being greatly preferred which grow in a dry soil. The archer's reed forms a peculiar species, as we have already stated; but that of Crete has the longest intervals between the joints, and when subjected to heat is capable of being rendered perfectly pliable at pleasure. The leaves, too, constitute different varieties, not only by their number, but their colour also. The reed of Laconia is spotted, and throws out a greater number of shoots at the lower extremities; being very similar in nature, it is thought, to the reeds that we find growing about stagnant waters, and unlike those of the rivers, in being covered with leaves of considerable length; which, climbing upwards, embrace the stem to a considerable distance above the joints. There is also an obliquely-spreading reed, which does not shoot upwards to any height, but spreads out like a shrub, keeping close to the earth; this reed is much sought by animals when young, and is known by some persons as the elegia. There is in Italy, too, a substance found in the marsh-reeds, called by the name of adarca: it is only to be found issuing from the cuter skin, below the flossy head of the plant, and is particularly beneficial to the teeth, having, in fact, an equal degree of pungency with mustard.

The terms of admiration in which they are spoken of by the ancients compels me to enter into some more minute details relative to the reed-beds of Lake Orchomenus. Characias was the name given there to a reed of stout and compact quality, while a thinner one was known as the plotias; this last was to be found growing on the floating islands there, while the former grew upon the banks that were covered by the waters of the lake. A third kind again, which had the name of "auleticon," was the same that is now known as the musical pipe reed. This reed used to take nine years to grow, as it was for that period that the waters of the lake were continually on the increase; it used to be looked upon as a prodigy of evil omen, if at the end of its rise its waters

remained overflowing so long as a couple of years; a thing that was observed at the period of the Athenian disasters at Cheronæa, and on various other occasions. This lake has the name of Lebaïda, at the part where the river Cephissus enters it.

When this inundation has lasted so long as a year, the reed is found large enough to be available for the purposes of fowling: at this period it used to be called *zeugites*. On the other hand, when the waters subsided at an earlier period, the reeds were known as *bombyciæ*, being of a more slender form. In this variety, too, the leaf of the female plant was broader and whiter than that of the others, while that upon which there was little or no down bore the name of the eunuch reed. The stem of this last variety was used for the manufacture of concert flutes. I must not here pass by in silence the marvellous care which the ancients lavished upon these instruments, a thing which will, in some measure, plead as an apology for the manufacture of them at the present day of silver in preference. The reed used to be cut, as it was then looked upon as being in the best condition, at the rising of *Arcturus*; an usage which prevailed down to the time of *Antigenides*, the musician, and while flute-playing was of a more simple style. Being thus prepared, the reeds became fit for use in the course of a few years. At that period even the reed required considerable seasoning to render it pliable, and to be instructed, as it were, in the proper modulation of its sounds; the mouthpiece and stops being naturally contracted, and so producing a music better adapted to the theatrical taste of the day. But in later times, when the music became more varied, and luxury began to exercise its influence upon the musical taste, it became the general usage to cut the reeds before the summer solstice, and to make them fit for use at the end of three months; the stops and mouth-piece being found, when the reeds were cut at that period, to be more open and better adapted for the modifications of sound: it is in this state that the reed is used for similar purposes at the present day. In those times it was a very general persuasion also, that every pipe ought to have the tongue of its own mouth-piece cut from the same reed as itself, and that a section from the part nearest the root was best adapted to form the left-handed flute, and from the part adjoining the top the right-handed one: those reeds, too, were considered immeasurably superior, which had been washed by the waters of *Cephissus* itself.

At the present day the sacrificial pipes used by the Tuscans are made of box-wood, while those employed at the games are made of the lotus, the bones of the ass, or else silver. The fowler's reeds of the best quality are those of *Panormus*, and the best reeds for fishing-rods come from *Abarita* in Africa.

CHAP. 67.

THE VINE-DRESSERS' REED.

The reed is employed in Italy more particularly, as a support for the vine. Cato recommends that it should be planted in a damp situation, the soil being first turned up with a double mattock, and a distance of three feet left between the young layers; he says, too, that the wild asparagus from which the cultivated species is produced, may be planted together with it, as they agree particularly well together.

(37.) He says also that the willow may be planted in its vicinity, than which there is no aquatic plant of more general utility, although the poplar may be preferred for the training of the vine, and the support of the Cæcuban grape; although, too, the alder affords a more efficient protection by the hedges it forms, and, planted in the very water, makes a rampart along the banks in defence of the adjoining country against the violence of the rivers when they overflow; when cut down, too, this last tree is useful for the innumerable suckers which it throws out.

Detailed table of contents

CHAP. 68.

THE WILLOW: EIEGT VARIETIES OF IT.

Of the willow, too, there are several varieties. One of them throws out its branches to a considerable height; and these, coupled together, serve as perches for the vine, while the bark around the tree itself is used for withes. Others, again, of a more pliable nature, supply a flexible twig, which is used for the purpose of tying; while others throw out osiers of remarkable thinness, adapted by their suppleness and graceful slenderness for the manufacture of wicker-work. Others, again, of a stouter make, are used for weaving panniers, and many other utensils employed in agriculture; while from a whiter willow the bark is peeled off, and, being remarkably tractable, admits of various utensils being made of it, which require a softer and more pliable material than leather: this last is also found particularly useful in the construction of those articles of luxury, reclining chairs. The willow, when cut, continues to thrive, and, indeed, throws out more thickly from the top, which, when closely clipped, bears a stronger resemblance to a closed fist than the top of a stump. It is a tree, which, in my opinion, deserves to be placed by no means in the lowest rank of trees; for there is none that will yield a more certain profit, which can be cultivated at less expense, or which is less liable to be influenced by changes in the weather.

Detailed table of contents

CHAP. 69.

TREES IN ADDITION TO THE WILLOW, WHICH ARE OF USE IN MAKING WITHEs.

Cato considers the culture of the willow as deserving to hold the third rank in estimation, and he gives it precedence to the cultivation of the olive, tillage for corn, or laying out land for pasture. It is not, however, because the willow is the only tree that produces withes; for they may be procured also from the broom, the poplar, the elm, the blood-red cornel, the birch, and the reed itself when split, or else the leaves of that plant, as we know to be the case in Liguria. The vine, also, will furnish them; the bramble, too, with the thorns removed, as well as the twisted hazel. It is a very singular thing, that a wood after it has been beaten and pounded should be found all the stronger for making withes, but such is a striking peculiarity that exists in the willow. The Greek red willow is split for this purpose: while the willow of Ameria is whiter but more brittle, for which reason it is used in an uncut state for tying. In Asia there are three varieties known of the willow; the black willow, which is best adapted for making withes, the white willow, employed for various agricultural purposes, and a third, which is shorter than the others, and known as the helix.

With us, also, there is the same number of denominations given to as many varieties of the willow; one being known as the viminal or purple willow, another as the nitelina, from its resemblance to the colour of the nitela, thinner in the trunk than the preceding one, and the third as the Gallic kind, being the thinnest of them all.

CHAP. 70.

RUSHES: CANDLE-RUSHES: RUSHES FOR THATCHING.

The rush, so frail in form, and growing in marshy spots, cannot be reckoned as belonging to the shrubs, nor yet to the brambles or the stalk plants; nor, indeed, in strict justice, to any of the classes of plants except one that is peculiarly its own. It is extensively used for making thatch and matting, and, with the outer coat taken off, for making candles and funeral torches. In some places, however, the rush is more hard and firm: thus, for instance, it is employed not only by the sailors on the Padus for making the sails of boats, but for the purposes of sea-fishing as well, by the fishermen of Africa, who, in a most preposterous manner, hang the sails made of it behind the masts. The people, too, of Mauritania thatch their cottages with rushes; indeed, if we look somewhat closely into the matter, it will appear that the rush is held in pretty nearly the same degree of estimation there as the papyrus is in the inner regions of the world.

Detailed table of contents

CHAP. 71.

THE ELDER: THE BRAMBLE.

Of a peculiar nature, too, though to be reckoned among the water-plants, is the bramble, a shrub-like plant, and the elder, which is of a spongy nature, though not resembling giant fennel, from having upon it a greater quantity of wood. It is a belief among the shepherds that if they cut a horn or trumpet from the wood of this tree, it will give all the louder sound if cut in a spot where the shrub has been out of hearing of the crowing of the cock. The bramble bears mulberries, and one variety of it, known as the cynosbatos, bears a flower similar to the rose. There is a third variety, known to the Greeks as the Idæan bramble, from the place where it grows: it is slighter than the others, with smaller thorns, and not so hooked. Its flower, mixed with honey, is employed as an ointment for sore eyes and erysipelas: and an infusion of it in water is used for diseases of the stomach.

The elder bears a small black berry, which contains a viscous juice, employed more particularly for staining the hair. The berries, too, are boiled in water and eaten.

Detailed table of contents

CHAP. 72. (38.)

THE JUICES OF TREES.

There is a juice in the bark of trees, which must be looked upon as their blood, though it is not of a similar nature in all. In the fig it is of a milky consistency, and has the peculiar property of curdling milk, and so forming cheese. In the cherry-tree this juice is gummy, in the elm clammy, in the apple viscous and fatty, while in the vine and the pear it is watery. The more viscous this humour is, the more long-lived the tree. In a word, we find in the bodies of trees-as with all other beings that are animated-skin, blood, flesh, sinews, veins, bones, and marrow; the bark serving them in place of skin. It is a singular fact connected with the mulberry-tree, that when the medical men wish to extract its juice, if the incision is lightly made, by a blow with a stone, and at the second hour of the day in spring, the juice will flow: but if, on the other hand, a wound is inflicted to any depth, it has all the appearance of being dried up.

Immediately beneath the bark in most trees there is a fatty substance, which, from its colour, has obtained the name of alburnum: it is soft, and is the very worst part of the wood, and in the robur even will very easily rot, being particularly liable to wood-worm, for which reason it is invariably removed. Beneath this fat lies the flesh of the tree, and then under that, its bones, or, in other words, the choicest part of the wood. Those trees which have a dry wood, the olive, for instance, bear fruit every other year only: this is more the case with them than with those the wood of which is of a fleshy nature, such as the cherry, for instance. It is not all trees, too, that have this fat and flesh in any abundance, the same as we find to be the case among the more active animals. The box, the cornel, and the olive have none at all, nor yet any marrow, and a very small proportion, too, of blood. In the same way, too, the service-tree has no bones, and the elder no flesh, while both of them have marrow in the greatest abundance. Reeds, too, have hardly any flesh.

Detailed table of contents

CHAP. 73.

TE VEINS AND FIBRES OF TREES.

In the flesh of some trees we find both fibres and veins: they are easily distinguished. The veins are larger, while the fibres are of whiter material, and are to be found in those woods more particularly which are easily split. Hence it is that if the ear is applied to the extremity of a beam of wood, however long, a tap with a graver even upon the other end may be distinctly heard, the sound penetrating by the passages which run straight through it: by these means it is that we ascertain whether timber runs awry, or is interrupted by knots. The tuberosities which we find on trees resemble the kernels that are formed in flesh: they contain neither veins nor fibres, but only a kind of tough, solid flesh, rolled up in a sort of ball: it is these tuberosities that are the most esteemed parts in the citrus and the maple. As to the other kinds of wood which are employed for making tables, the trees are split into planks lengthwise, and the parts are then selected along which the fibres run, and properly rounded; for the wood would be too brittle to use if it were cut in segments crosswise. in the beech, the grain of the fibrous part runs crosswise; hence it is that the ancients held in such high esteem all vessels made with the wood of it. Manius Curius made oath, on one occasion, that he had not touched an article of all the spoil except a single oil cruet of beech, to use for sacrificing. Wood is always put lengthwise into the water to season, as that part which was nearest the root will sink to a greater depth than the other. In some wood there is fibre, without veins, and merely consisting of filaments slightly knit together: wood of this nature is remarkably fissile. Other wood, again, is more easily broken across than split, such as the wood of those trees that have no fibre, the olive and the vine, for instance: on the other hand, in the fig-tree, the whole of the body consists of flesh. The holm-oak, the cornel, the robur, the cytissus, the mulberry, the ebony, the lotus, and the other trees which we have mentioned as being destitute of marrow, consist entirely of bone. All these woods are of a blackish colour, with the exception of the cornel, of which glossy yellow hunting-spears are made, marked with incisions for their further embellishment. In the cedar, the juniper, and the larch, the wood is red.

(39.) In Greece the female larch furnishes a wood which is known as ægis, and is just the colour of honey. This wood has been found to be proof against decay, and forms the pannels used by painters, being never known to gape or split; the portion thus employed is that which lies nearest to the pith. In the fir-tree this part is called "leuson" by the Greeks. In the cedar, too, the hardest part is the wood that lies nearest to the sap: after the slimys pith has been carefully removed, it has a similar degree of hardness to the bones in the bodies of animals. It is said, too, that in Greece the inner part of the elder is

remarkably firm: indeed, those whose business it is to make hunting spears, prefer this material to all others, it being a wood composed wholly of skin and bone.

Detailed table of contents

CHAP. 74.

THE FELLING OF TREES.

The proper time for felling trees that are wanted for barking, the round, tapering trees, for instance, that are employed in temples and for other purposes, is at the period of germination: for at other times it is quite impossible to detach the bark from the rotten wood that adheres to it, while the wood itself assumes a blackish hue. Squared logs, and wood from which the bark has been lopped, are generally cut in the period that intervenes between the winter solstice and the prevalence of the west winds; or else, if it is necessary to anticipate that period, at the setting of Arcturus and before that of the Lyre, the very earliest period being the summer solstice: the days of these respective constellations will be mentioned in the appropriate place.

In general it is looked upon as quite sufficient to use all due precaution that a tree is not rough-hewn before it has borne its yearly crop. The robur, if cut in spring, is subject to the attacks of wood-worm, but if cut in winter, will neither rot nor warp: otherwise it is very liable to bend and become awry, as well as to crack; the same is the case, too, with the cork-tree, even if cut down at the proper time. The state of the moon, too, is of infinite importance, and it is generally recommended that trees should be cut only between the twentieth and the thirtieth days of the month. It is generally agreed, however, by all, that it is the very best time for felling timber, when the moon is in conjunction with the sun, a day which is called by some persons the interlunium, and by others the moon's silence. At all events, it was under these circumstances that Tiberius Cæsar gave orders for the larches to be cut in Rhætia, that were required for the purpose of rebuilding the bridge of the Naumachia after it had been destroyed by fire. Some persons say that the moon ought not only to be in conjunction, but below the horizon as well, a thing that can only happen in the night. If the conjunction should chance to fall on the very day of the winter solstice, the timber, they say, that is then felled will be of everlasting duration; the next best being the timber that is cut when the conjunction coincides with the constellations previously mentioned. There are some, too, who add the rising of the Dog-star as a favourable time, and say that it was at this period that the timber was cut which was employed in building the Forum of Augustus.

Wood which is intended for timber ought to be cut neither when too young nor too old. Some persons, too — and the practice is by no means without its utility — cut round the tree as far as the pith, and then leave the timber standing, so that all the juices may be enabled to escape. Going back to ancient times, it is a remarkable fact, that in the first Punic War the fleet commanded by Duillius was on the water within sixty days from the time the timber was cut: and, what is still more so, Piso relates that King Hiero had

two hundred and twenty ships wholly constructed in forty-five days: in the second Punic War, too, the fleet of Scipio was at sea the fortieth day after the axe had been put to the tree. Such is the energy and dispatch that can be displayed on occasions of emergency.

[Detailed table of contents](#)

CHAP. 75.

THE OPINION OF CATO ON THE FELLING OF TIMBER.

Cato, a man of consummate authority in all practical matters, expresses himself in relation to timber to the following effect:— “For making presses, employ the wood of the sappinus in preference. When you root up the elm, the pine, the nut- tree, or, indeed, any other kind of tree, mind and do so when the moon is on the wane, after midday, and when there is no south wind blowing. The proper time for cutting a tree is when the seed is ripe, but be careful not to draw it away or plane it while the dew is falling.” He then proceeds to say—” Never touch the timber, except when the moon is on the change, or else at the end of the second quarter: at those periods you may either root up the tree, or fell it as it stands. The next seven days after the full moon are the best of all for grubbing up a tree. Be particularly careful, too, not to rough- hew timber, or, indeed, to cut or touch it, unless it is perfectly dry; and by no means while it is covered with frost or dew.”

The Emperor Tiberius used also to observe the changes of the moon for cutting his hair. M. Varro has recommended that the hair should be cut at full moon only, if we would avoid baldness.

Detailed table of contents

CHAP. 76.

THE SIZE OF TREES: THE NATURE OF WOOD: THE SAPPINUS.

From the larch, and still more the fir, after it has been cut, a liquid flows for a considerable period: these are the loftiest and straightest of all the trees. The fir is preferred for making the masts and sailyards of ships, on account of its comparative lightness. It is a common feature with these trees, in common with the pine, to have four rows of veins running along the wood, or else two, or sometimes only one. The heart of these trees is peculiarly well adapted for joiners' work, and the best wood of all is that which has four layers of veins, it being softer than the rest: men of experience in these matters can instantly form a judgment of the quality from the bark. That part in the fir which is nearest to the ground is free from knots: when soaked in river water in the way we have already mentioned, and then barked, the wood of this part is known as sappinus; while that of the upper part, which is harder and knotty, goes by the name of "fusterna." In trees, the side which looks towards the northeast is the most robust, and it is universally the case, that those which grow in moist and damp localities are of inferior quality, while in those which grow in warm and sunny spots, the wood is more compact and durable; hence it is, that at Rome the fir is preferred that grows on the shores of the Tyrrhenian Sea to that of the shores of the Adriatic.

There are also considerable differences in the qualities of these trees according to the country of their growth: the most esteemed are those of the Alps and the Apennines; in Gaul, those of Jura and Mount Vogesus; those also of Corsica, Bithynia, Pontus, and Macedonia; while the firs of Ænea and Arcadia are of inferior quality. Those, however, of Parnassus and Eubœa are the worst of all, the trees being branchy and knotted, and the wood very apt to rot. As for the cedar, those of Crete, Africa, and Syria are the most esteemed. Wood, if well rubbed with oil of cedar, is proof against wood-worm and decay. The juniper, too, has the same virtues as the cedar; in Spain it grows to a very considerable size, in the territory of the Vacæi more particularly: the heart of this tree, too, is universally more firm and solid than cedar even. A general fault in all wood is that known as cross-grain, which is formed by contortions of the knots and veins. In the wood of some trees there are to be found knurs, like those in marble; these knurs are remarkably hard, and offer a resistance like that of a nail, to the great injury of the saw: in some cases, also, they are formed accidentally, from either a stone, or the branch of another tree lodging there, and being absorbed in the body of the tree.

In the Forum at Megara there long stood a wild olive upon which warriors who had distinguished themselves by their martial powers had been in the habit of suspending their arms. In the lapse of time the bark of this tree had closed, and quite concealed these arms from view. Upon it, however,

depended the fate of the city; for it had been announced by an oracle, that when a tree there should bring forth arms, the fall of the city would be close at hand: and such, in fact, was the result, when the tree was cut down and greaves and helmets were found within the wood. It is said that stones found under these circumstances have the property of preventing abortion.

(40.) It is generally thought that the largest tree that has ever been seen, was the one that was exhibited at Rome, by Tiberius Cæsar, as an object of curiosity, upon the bridge of the Naumachia previously mentioned. It had been brought thither along with other timber, and was preserved till the construction of the amphitheatre of the Emperor Nero: it was a log of larch, one hundred and twenty feet long, and of an uniform thickness of a couple of feet. From this fact we can form an estimate of the original height of the tree; indeed, measured from top to bottom it must have been originally of a length that is almost incredible. In our own time, too, in the porticos of the Septa, there was a log which had been left there by M. Agrippa, as being equally an object of curiosity, having been found too large to be used in the building of the vote office there: it was twenty feet shorter than the one previously mentioned, and a foot-and-a-half in thickness. There was a fir, too, that was particularly admired, when it formed the mast of the ship, which brought from Egypt, by order of the Emperor Caius, the obelisk that was erected in the Vaticanian Circus, with the four blocks of stone intended for its base. It is beyond all doubt that there has been seen nothing on the sea more wonderful than this ship: one hundred and twenty thousand modii of lentils formed its ballast; and the length of it took up the greater part of the left side of the harbour at Ostia. It was sunk at that spot by order of the Emperor Claudius, three moles, each as high as a tower, being built upon it; they were constructed with cement which the same vessel had conveyed from Puteoli. It took the arms of four men to span the girth of this tree, and we not unfrequently hear of the price of masts for such purposes, as being eighty thousand sesterces or more: rafts, too, of this wood are sometimes put together, the value of which is forty thousand. In Egypt and Syria, it is said, the kings, for want of fir, used to employ cedar for building their ships: the largest cedar that we find mentioned is said to have come from Cyprus, where it was cut to form the mast of a galley of eleven tiers of oars that belonged to Demetrius: it was one hundred and thirty feet in length, and took three men to span its girth. The pirates of Germany navigate their seas in vessels formed of a single tree hollowed out: some of these will hold as many as thirty men.

Of all woods, the most compact, and consequently the heaviest, are the ebony and the box, both of them of a slender make. Neither of these woods will float in water, nor, indeed, will that of the cork tree, if the bark is removed; the same is the case, too, with the wood of the larch. Of the other woods, the driest is that of the tree known at Rome as the lotus, and next, that of the robur, when the white sap has been removed. The wood of the robur is dark, and that of the cytissus still more so, approaching, in fact, the nearest of

all to the colour of ebony; though there are not wanting writers who assert that the wood of the Syrian terebinth is darker. An artist of the name of Thericles is highly spoken of for his skill in turning goblets from the wood of the terebinth: and, indeed, that fact is a proof of the goodness of the wood. Terebinth is the only wood that requires to be rubbed with oil, and is improved thereby. Its colour is imitated remarkably well with the walnut and the wild pear, which have its peculiar tint imparted to them by being boiled in colouring liquid. The wood of all the trees of which we have here made mention is firm and compact. Next after them comes the cornel, although it can hardly be looked upon as timber, in consequence of its remarkable slimness; the wood of it, in fact, is used for hardly any other purpose than the spokes of wheels, or else for making wedges for splitting wood, and pins or bolts, which have all the hardness of those of iron. Besides these, there are the holm-oak, the wild and the cultivated olive, the chesnut, the yoke-elm, and the poplar. This last is mottled similarly to the maple, and would be used for joiners' work if wood could be good for anything when the branches are so often lopped: that acting upon the tree as a sort of castration, and depriving it of its strength. In addition to these facts, most of these trees, but the robur more particularly, are so extremely hard, that it is quite impossible to bore the wood till it has been soaked in water; and even then, a nail once driven home cannot be drawn out again. On the other hand, a nail has no hold in cedar. The wood of the lime is the softest of all, and, as it would appear, the hottest by nature; a proof of this, they say, is the fact that it will turn the edge of the adze sooner than any other wood. In the number, also, of the trees that are hot by nature, are the mulberry, the laurel, the ivy, and all those woods from which fire is kindled by attrition.

Detailed table of contents

CHAP. 77.

METHODS OF OBTAINING FIRE FROM WOOD.

This is a method which has been employed by the outposts of armies, and by shepherds, on occasions when there has not been a stone at hand to strike fire with. Two pieces of wood are rubbed briskly together, and the friction soon sets them on fire; which is caught on dry and inflammable substances, fungi and leaves being found to ignite the most readily. There is nothing superior to the wood of the ivy for rubbing against, or to that of the laurel for rubbing with. A species of wild vine, too — not the same as the *labrusca* — which climbs up other trees like the ivy, is highly approved of. The coldest woods of all are those of the aquatic trees; but they are the most flexible also, and for that reason the best adapted for the construction of bucklers. On an incision being made in them, they will contract immediately, and so close up their wounds, at the same time rendering it more difficult for the iron to penetrate: in the number of these woods are the fig, the willow, the lime, the birch, the elder, and both varieties of the poplar.

The lightest of all these woods, and consequently the most useful, are the fig and the willow. They are all of them employed, however, in the manufacture of baskets and other utensils of wicker-work; while, at the same time, they possess a degree of whiteness and hardness which render them very well adapted for carving. The plane has considerable flexibility, but it is moist and slimy like the alder. The elm, too, the ash, the mulberry, and the cherry, are flexible, but of a drier nature; the wood, however, is more weighty. The elm is the best of all for retaining its natural toughness, and hence it is more particularly employed for socket beams for hinges, and cases for the pannelling of doors, being proof against warping. It is requisite, however, that the beam to receive the hinge should be inverted when set up, the top of the tree answering to the lower hinge, the root to the upper. The wood of the palm and the cork-tree is soft, while that of the apple and the pear is compact. Such, however, is not the case with the maple, its wood being brittle, as, in fact, all veined woods are. In every kind of tree, the varieties in the wood are still more augmented by the wild trees and the males. The wood, too, of the barren tree is more solid than that of the fruit-bearing ones, except in those species in which the male trees bear fruit, the cypress and the cornel, for instance.

CHAP. 78.

TREES WHICH ARE PROOF AGAINST DECAY: TREES WHICH NEVER SPLIT.

The following trees are proof against decay and the other- wise injurious effects of age — the cypress, the cedar, the ebony, the lotus, the box, the yew, the juniper, and both the wild and cultivated olive. Among the others, the larch, the robur, the cork-tree, the chesnut, and the walnut are also remarkably durable. The cedar, cypress, olive, and box are never known to split or crack spontaneously.

Detailed table of contents

CHAP. 79.

HISTORICAL FACTS CONNECTED WITH THE DURABILITY OF WOOD.

Of all the woods, the ebony, the cypress, and the cedar are considered to be the most durable, a good proof of which is to be seen in the timber of which the Temple of Diana at Ephesus is built: it being now four hundred years since it was erected, at the joint expense of the whole of Asia; and, what is a well-known fact, the roof is wholly constructed of planks of cedar. As to the statue of the goddess, there is some doubt of what wood it is made; all the writers say that it is ebony, with the exception of Mucianus, who was three times consul, one of the very latest among the writers that have seen it; he declares that it is made of the wood of the vine, and that it has never been changed all the seven times that the temple has been rebuilt. He says, too, that it was Endæus who made choice of this wood, and even goes so far as to mention the artist's name, a thing that really surprises me very much, seeing that he attributes to it an antiquity that dates before the times of Father Liber, and of Minerva even. He states, also, that, by the aid of numerous apertures, it is soaked with nard, in order that the moist nature of that drug may preserve the wood and keep the seams close together: I am rather surprised, however, that there should be any seams in the statue, considering the very moderate size it is. He informs us, also, that the doors are made of cypress, and that the wood, which has now lasted very nearly four hundred years, has all the appearance of new. It is worthy of remark, too, that the wood of these doors, after the pieces had been glued together, was left to season four years before they were put up: cypress was made choice of from the circumstance that it is the only kind of wood that maintains its polish to all future time.

And have we not the statue of Vejovis, also, made of cypress, still preserved in the Capitol, where it was consecrated in the year of the City 661? The Temple of Apollo, too, at Utica, is equally celebrated: there we may see beams of cedar still in existence, and in just the same condition in which they were when erected at the first building of that city, eleven hundred and seventy-eight years ago. At Saguntum, too, in Spain, there is a temple of Diana, which was brought thither by the original founders of the place, from the island of Zacynthus, in the year 200 before the taking of Troy, Bocchus says — It is preserved beneath the town, they say. Hannibal, being induced thereto by feelings of religious veneration, spared this temple, and its beams, made of juniper, are still in existence at this very day. But the most memorable instance of all is that of the temple which was dedicated to the same goddess at Aulis, several ages before the Trojan War: of what wood, however, it was originally built is a fact that has been long lost in oblivion. Speaking in general terms, we may say that those woods are of the greatest durability which are the most odoriferous.

Next to those woods of which we have just spoken, that of the mulberry is held in the highest degree of esteem, and it will even turn black when old. There are some trees, again, that are more durable than others, when employed for certain purposes. The wood of the elm lasts the best in the open air, that of the robur when buried in the ground, and that of the quercus when exposed to the action of water: indeed, the wood of this last, if employed in works above ground, is apt to split and warp. The wood of the larch thrives best in the midst of moisture; the same is the case, too, with that of the black alder. The wood of the robur spoils by exposure to the action of sea-water. The beech and the walnut are far from disapproved of for constructions under water, and, in fact, these are the principal woods, too, that are used for works under ground: the same is the case, also, with the juniper; which is equally serviceable when exposed to the atmosphere. The woods of the beech and the cirrus very quickly deteriorate, and that of the æsculus will not withstand the action of water. On the other hand, the alder, when driven into the ground in marshy localities, is of everlasting duration, and able to support the very heaviest weights. The wood of the cherry is strong, while those of the elm and the ash are pliable, though apt to warp: these last will still retain their flexibility, and be less liable to warp, if the wood is left to stand and dry upon the trunk after the pith has been cut around. It is said that the larch, when used for sea-going ships, is liable to the attacks of the teredo, as, in fact, all the woods are, with the exception of the wild and cultivated olive. It is a fact, too, that there are some woods that are more liable to spoil in the sea, and others in the ground.

[Detailed table of contents](#)

CHAP. 80. (41.)

VARIETIES OF THE TEREDO.

There are four kinds of insects that attack wood. The teredo has a head remarkably large in proportion to the other part of the body, and gnaws away the wood with its teeth: its attacks, however, are confined solely to the sea, and it is generally thought that this is the only insect that is properly so called. The wood-worm that prevails on the land is known as the “tinea,” while those which resemble a gnat in appearance are called “thripes.” The fourth kind of wood-worm belongs to the maggot class; some of them being engendered by the corruption of the juices of the wood itself, and others being produced, just as in the trees, by the worm known as the cerastes. When this worm has eaten away enough of the wood to enable it to turn round, it gives birth to another. The generation of these insects is prevented, however, by the bitterness that exists in some woods, the cypress, and the hardness of others, the box, for instance.

It is said, too, that the fir, if barked about the time of budding, and at the period of the moon already mentioned, will never spoil in water. The followers of Alexander the Great have left a statement that, at Tylos, an island in the Red Sea, there are trees, of which ships are built, the wood of which has been found uninjured at the end of two hundred years, even if it has been under water all that time. They say, also, that in the same island there is a certain shrub, about the thickness of a walking-stick only, and spotted like a tiger’s skin: it is very heavy, and will break like glass if it happens to fall upon a hard substance.

Detailed table of contents

CHAP. 81. (42.)

THE WOODS USED IN BUILDING.

We have in Italy some woods that are apt to split of themselves: to prevent this, architects recommend that they should be first seasoned in manure and then dried, in order to render them proof against the action of the atmosphere. The woods of the fir and larch are well adapted, even when used transversely, for the support of heavy burdens; while the robur and the olive are apt to bend and give way under a weight. The wood of the poplar and the palm are also strong, but this last will bend, though in a manner different from the others; for, while in all other instances the wood bends downwards, in the palm it bends in the contrary direction, and forms an arch. The woods of the pine and the cypress are proof against decay and all attacks of wood-worm. The walnut is easily warped, but we sometimes see beams even made of it. It gives warning, however, before it breaks, by a loud cracking noise; such was the case at Antandros, at the public baths there — the bathers took the alarm upon hearing the beams crack, and made their escape. The pine, the pitch-tree, and the alder are employed for making hollow pipes for the conveyance, of water, and when buried in the earth will last for many years. If, however, they are not well covered over, they will very soon rot; and the resistance they offer to decay will increase in a most surprising degree if the outer surface as well is left in contact with the water.

Detailed table of contents

CHAP. 82.

CARPENTERS' WOODS.

The wood of the fir is strongest in a vertical position: it is remarkably well adapted for the pannels of doors, and all kinds of in-door joiners' work, whether in the Grecian, the Campanian, or the Sicilian style. The shavings of this wood when briskly planed, always curl up in circles like the tendrils of the vine. This wood, too, unites particularly well with glue: it is used in this state for making vehicles, and is found to split sooner in the solid parts than in a place where the pieces have been glued together.

[Detailed table of contents](#)

CHAP. 83. (43.)

WOODS UNITED WITH GLUE.

Glue, too, plays one of the principal parts in all veneering and works of marqueterie. For this purpose, the workmen usually employ wood with a threaded vein, to which they give the name of “ferulea,” from its resemblance to the grain of the giant fennel, this part of the wood being preferred from its being dotted and wavy. In every variety there are some woods to be found that will not take the glue, and which refuse to unite either with wood of the same kind or of any other; the wood of the robur for example. Indeed, it is mostly the case that substances will not unite unless they are of a similar nature; a stone, for instance, cannot be made to adhere to wood. The wood of the service-tree, the yoke-elm, the box, and, in a less degree, the lime, have a particular aversion to uniting with the cornel. All the yielding woods which we have already spoken of as flexible readily adapt themselves to every kind of work; and in addition to them, the mulberry and the wild fig. Those which are moderately moist are easily sawn and cut, but dry woods are apt to give way beyond the part that is touched by the saw; while, on the other hand, the green woods, with the exception of the robur and the box, offer a more obstinate resistance, filling the intervals between the teeth of the saw with sawdust, and rendering its edge uniform and inert; it is for this reason that the teeth are often made to project right and left in turns, a method by which the saw-dust is discharged. The ash is found the most pliable wood of all for working; and, indeed, for making spears it is better even than the hazel, being lighter than the cornel, and more pliable than the wood of the service-tree. The Gallic variety is so supple, that it is employed in the construction of vehicles even. The elm would rival the trunk of the vine for some purposes, were it not that its weight is so much against it.

Detailed table of contents

CHAP. 8.

VENEERING.

The wood, too, of the beech is easily worked, although it is brittle and soft. Cut into thin layers of veneer, it is very flexible, but is only used for the construction of boxes and desks. The wood, too, of the holm-oak is cut into veneers of remarkable thinness, the colour of which is far from unsightly; but it is more particularly where it is exposed to friction that this wood is valued, as being one to be depended upon; in the axle-trees of wheels, for instance; for which the ash is also employed, on account of its pliancy, the holm-oak for its hardness, and the elm, for the union in it of both those qualities. There are also various workman's tools made of wood, which, though but small, are still remarkably useful; in this respect, it is said that the best materials for making auger handles are the wild olive, the box, the holm-oak, the elm, and the ash. Of the same woods also mallets are made; the larger ones, however, are made of the pine and the holm-oak. These woods, too, have a greater degree of strength and hardness if cut in season than when hewn prematurely; indeed, it has been known for hinge-jambs, made of olive, a wood of remarkable hardness, after having remained a considerable time on the spot, to put out buds like a growing plant. Cato recommends levers to be made of holly, laurel, or elm; and Hyginus speaks highly of the yoke-elm, the holm-oak, and the cerrus, for the handles of agricultural implements.

The best woods for cutting into layers, and employing as a veneer for covering others, are the citrus, the terebinth, the different varieties of the maple, the box, the palm, the holly, the holm-oak, the root of the elder, and the poplar. The alder furnishes also, as already stated, a kind of tuberosity, which is cut into layers like those of the citrus and the maple. In all the other trees the tuberosities are of no value whatever. It is the central part of trees that is most variegated, and the nearer we approach to the root the smaller are the spots and the more wavy. It was in this appearance that originated that requirement of luxury which displays itself in covering one tree with another, and bestowing upon the more common woods a bark of higher price. In order to make a single tree sell many times over, laminæ of veneer have been devised; but that was not thought sufficient — the horns of animals must next be stained of different colours, and their teeth cut into sections, in order to decorate wood with ivory, and, at a later period, to veneer it all over. Then, after all this, man must go and seek his materials in the sea as well! For this purpose he has learned to cut tortoise-shell into sections; and of late, in the reign of Nero, there was a monstrous invention devised of destroying its natural appearance by paint, and making it sell at a still higher price by a successful imitation of wood.

It is in this way that the value of our couches is so greatly enhanced; it is in

this way, too, that they bid the rich lustre of the terebinth to be outdone, a mock citrus to be made that shall be more valuable than the real one, and the grain of the maple to be feigned. At one time luxury was not content with wood; at the present day it sets us on buying tortoiseshell in the guise of wood.

Detailed table of contents

CHAP. 85. (44.)

THE AGE OF TREES. A TREE THAT WAS PLANTED BY THE FIRST SCIPIO AFRICANUS. A TREE AT ROME FIVE HUNDRED YEARS OLD.

The life of some trees might really be looked upon as of infinite duration, if we only think of the dense wilds and inaccessible forests in some parts of the world. In relation, however, to those, the date of which is still within the memory of man, there are some olive-trees still in existence at Liternum, which were planted by the hand of the first Scipio Africanus, as also a myrtle there of extraordinary size; beneath them there is a grotto, in which, it is said, a dragon keeps watch over that hero's shade. There is a lotus tree in the open space before the Temple of Lucina at Rome, which was built in the year of the City 379, a year in which the republic had no magistrates. How much older the tree is than the temple, is a matter of doubt; but that it is older is quite certain, for it was from that same grove that the goddess Lucina derived her name; the tree in question is now about four hundred and fifty years old. The lotus tree, which is known as the Capillata, is still older than this, though it is uncertain what is its age; it received that name from the circumstance of the Vestal Virgins suspending locks of their hair from it.

[Detailed table of contents](#)

CHAP. 86.

TREES AS OLD AS THE CITY.

There is another lotus in the Vulcanal, which Romulus erected with the tenth part of the spoil taken from the enemy: according to Massurius, it is generally considered to be as old as the City. The roots of this tree penetrate as far as the Forum of Cæsar, right across the meeting-places of the municipalities. There was a cypress of equal age growing with it till towards the latter part of Nero's reign, when it fell to the ground, and no attempts were made to raise it again.

Detailed table of contents

CHAP. 87.

TREES IN THE SUBURBAN DISTRICTS OLDER THAN THE CITY.

Still older than the City is the holm-oak that stands on the Vaticanian Hill: there is an inscription in bronze upon it, written in Etruscan characters, which states that even in those days it was an object of religious veneration. The foundation of the town of Tibur, too, dates many years before that of the City of Rome: there are three holm-oaks there, said to be more ancient than Tiburnus even, who was the founder of that place; the tradition is that in their vicinity he was inaugurated. Tradition states also that he was a son of Amphiaraüs, who died before Thebes, one generation before the period of the Trojan war.

Detailed table of contents

CHAP. 88.

TREES PLANTED BY AGAMEMNON THE FIRST YEAR OF THE TROJAN WAR:
OTHER TREES WHICH DATE FROM THE TIME THAT THE PLACE WAS CALLED
ILIAM, ANTERIOR TO THE TROJAN WAR.

There are some authors, too, who state that a plane-tree at Delphi was planted by the hand of Agamemnon, as also another at Caphyæ, a sacred grove in Arcadia. At the present day, facing the city of Ilium, and close to the Hellespont, there are trees growing over the tomb of Protesilaiis there, which, in all ages since that period, as soon as they have grown of sufficient height to behold Ilium, have withered away, and then begun to flourish again. Near the city, at the tomb of Ilus, there are some oaks which are said to have been planted there when the place was first known by the name of Ilium.

Detailed table of contents

CHAP. 89.

TREES PLANTED AT ARGOS BY HERCULES: OTHERS PLANTED BY APOLLO. A TREE MORE ANCIENT THAN ATHENS ITSELF.

At Argos an olive-tree is said to be still in existence, to which Argus fastened Io, after she had been changed into a cow. In the vicinity of Heraclea in Pontus, there are certain altars called after Jupiter surnamed Stratios; two oaks there were planted by Hercules. In the same country, too, is the port of Amycus, rendered famous by the circumstance that King Bcbryx was slain there. Since the day of his death his tomb has been covered by a laurel, which has obtained the name of the “frantic laurel,” from the fact that if a portion of it is plucked and taken on board ship, discord and quarrelling are the inevitable result, until it has been thrown overboard. We have already made mention of Aulocrene, a district through which you pass in going from Apamia into Phrygia: at this place they show a plane upon which Marsyas was hanged, after he had been conquered by Apollo, it having been chosen even in those days for its remarkable height. At Delos, also, there is a palm to be seen which dates from the birth of that divinity, and at Olympia there is a wild olive, from which Hercules received his first wreath: at the present day it is preserved with the most scrupulous veneration. At Athens, too, the olive produced by Minerva, is said still to exist.

Detailed table of contents

CHAP. 90.

TREES WHICH ARE THE MOST SHORT-LIVED.

On the other hand, the pomegranate, the fig, and the apple are remarkably short-lived; the precocious trees being still more so than the later ripeners, and those with sweet fruit than those with sour: among the pomegranates, too, that variety which bears the sweetest fruit lives the shortest time. The same is the case, too, with the vine, and more particularly the more fruitful varieties. Græcinus informs us that vines have lasted so long as sixty years. It appears, also, that the aquatic trees die the soonest. The laurel, the apple, and the pomegranate age rapidly, it is true, but then they throw out fresh shoots at the root. The olive must be looked upon, then, as being one of the most long-lived, for it is generally agreed among authors that it will last two hundred years.

[Detailed table of contents](#)

CHAP. 91.

TREES THAT HAVE BEEN RENDERED FAMOUS BY REMARKABLE EVENTS.

In the territory about the suburbs of Tusculum, upon a hill known by the name of Corne, there is a grove which has been consecrated to Diana by the people of Latium from time immemorial; it is formed of beeches, the foliage of which has all the appearance of being trimmed by art. Passienus Crispus, the orator, who in our time was twice consul, and afterwards became still more famous as having Nero for his step-son, on marrying his mother Agrippina, was passionately attached to a fine tree that grew in this grove, and would often kiss and embrace it: not only would he lie down, too, beneath it, but he would also moisten its roots with wine. In the vicinity of this grove there is a holm-oak, likewise of very considerable celebrity, the trunk of which is no less than thirty-four feet in circumference; giving birth to ten other trees of remarkable size, it forms of itself a whole forest.

Detailed table of contents

CHAP. 92.

PLANTS THAT HAVE NO PECULIAR SPOT FOR THEIR GROWTH: OTHERS THAT GROW UPON TREES, AND WILL NOT GROW IN THE GROUND. NINE VARIETIES OF THEM: CADYTAS, POLYPODION, PHAULIAS, HIPPOPHÆSTON.

It is a well-known fact that trees are killed by ivy. The mistletoe also has a similar influence, although it is generally thought that its injurious effects are not so soon perceptible: and, indeed, this plant, apart from the fruit that it bears, is looked upon as by no means the least remarkable. There are certain vegetable productions which cannot be propagated in the ground, and which grow nowhere but on trees; having no domicile of their own, they live upon others; such, for instance, is the case with the mistletoe, and a herb that grows in Syria, and is known as the “cadytas.” This last entwines around not only trees, but brambles even; in the neighbourhood of Tempe, too, in Thessaly, there is found a plant which is called “polypodion; the dolichos is found also, and wild thyme. After the wild olive has been pruned there springs up a plant that is known as “phaulias; while one that grows upon the fuller’s thistle is called the “hippophæston;” it has a thin, hollow stem, a small leaf, and a white root, the juice of which is considered extremely beneficial as a purgative in epilepsy.

Detailed table of contents

CHAP. 93.

THREE VARIETIES OF MISTLETOE. THE NATURE OF MISTLETOE AND SIMILAR PLANTS.

There are three varieties of the mistletoe. That which grows upon the fir and the larch has the name of stelis in Eubœa; and there is the hyphear of Arcadia. It grows also upon the quercus, the robur, the holm-oak, the wild plum, and the terebinth, but upon no other tree. It is most plentiful of all upon the quercus, and is then known as “adasphear.” In all the trees, with the exception of the holmoak and the quercus, there is a considerable difference in its smell and pungency, and the leaf of one kind has a disagreeable odour; both varieties, however, are sticky and bitter. The hyphear is the best for fattening cattle with; it begins, however, by purging off all defects, after which it fattens all such animals as have been able to withstand the purging. It is generally said, however, that those animals which have any radical malady in the intestines cannot withstand its drastic effects. This method of treatment is generally adopted in the summer for a period of forty days.

Besides the above, there is yet another difference in the mistletoe; that which grows upon the trees which lose their leaves, loses its leaves as well; while, on the other hand, that which grows upon evergreens always retains its leaves. In whatever way the seed may have been sown, it will never come to anything, unless it has been first swallowed and then voided by birds, the wood-pigeon more particularly, and the thrush: such being the nature of the plant, that it will not come to anything unless the seed is first ripened in the crop of the bird. It never exceeds a single cubit in height, and is always green and branchy. The male plant is fruitful, the female barren; sometimes, indeed, the male even bears no berry.

Detailed table of contents

CHAP. 94.

THE METHOD OF MAKING BIRDLIME.

Birdlime is made of the berries of the mistletoe, which are gathered at harvest, and while in an unripe state; for if the rainy season comes on, though they increase in size, the viscous juice is apt to lose its virtues. They are then dried, and when brought to a state of perfect aridity, are first pounded, and then put in water, in which they are left to rot for twelve days; this being, in fact, the only thing that finds improvement in decay. After this, they are again beaten in running water with a mallet, and after losing the outer coat there is only the viscous inner pulp remaining. This substance is birdlime; and after it has been thinned by the addition of walnut oil, it is found particularly useful for catching birds, it being quite sufficient if they only touch it with the wings.

Detailed table of contents

CHAP. 95.

HISTORICAL FACTS CONNECTED WITH THE MISTLETOE.

Upon this occasion we must not omit to mention the admiration that is lavished upon this plant by the Gauls. The Druids — for that is the name they give to their magicians — held nothing more sacred than the mistletoe and the tree that bears it, supposing always that tree to be the robur. Of itself the robur is selected by them to form whole groves, and they perform none of their religious rites without employing branches of it; so much so, that it is very probable that the priests themselves may have received their name from the Greek name for that tree. In fact, it is the notion with them that everything that grows on it has been sent immediately from heaven, and that the mistletoe upon it is a proof that the tree has been selected by God himself as an object of his especial favour.

The mistletoe, however, is but rarely found upon the robur; and when found, is gathered with rites replete with religious awe. This is done more particularly on the fifth day of the moon, the day which is the beginning of their months and years, as also of their ages, which, with them, are but thirty years. This day they select because the moon, though not yet in the middle of her course, has already considerable power and influence; and they call her by a name which signifies, in their language, the all-healing. Having made all due preparation for the sacrifice and a banquet beneath the trees, they bring thither two white bulls, the horns of which are bound then for the first time. Clad in a white robe the priest ascends the tree, and cuts the mistletoe with a golden sickle, which is received by others in a white cloak. They then immolate the victims, offering up their prayers that God will render this gift of his propitious to those to whom he has so granted it. It is the belief with them that the mistletoe, taken in drink, will impart fecundity to all animals that are barren, and that it is an antidote for all poisons. Such are the religious feelings which we find entertained towards trifling objects among nearly all nations.

Detailed table of contents

CHAP. 1. (1.)

TREES WHICH HAVE BEEN SOLD AT ENORMOUS PRICES.

WE have described the trees which grow spontaneously on land and in the sea, and it now remains for us to speak of those which owe their formation, properly speaking, rather than birth, to art and the inventive genius of man. Here, however, I cannot but express my surprise, that after the state of penury in which man lived, as already described, in primitive times, holding the trees of the forest in common with the wild beasts, and disputing with them the possession of the fruits that fell, and with the fowls of the air that of the fruits as they hung on the tree, luxury has now attached to them prices so enormous.

The most famous instance, in my opinion, of this excess, was that displayed by L. Crassus and Cneius Domitius Ahenobarbus. Crassus was one of the most celebrated of the Roman orators; his house was remarkable for its magnificence, though in some measure surpassed even by that of Q. Catulus, also upon the Palatine Hill; the same Catulus, who, in conjunction with C. Marius, defeated the Cimbri. But by far the finest house of all that period, it was universally acknowledged, was that of C. Aquilius, a Roman of Equestrian rank, situate upon the Viminal Hill; a house, indeed, that conferred a greater degree of celebrity upon him than even his acquaintance with the civil law. This, however, did not prevent Crassus being reproached with the magnificence of his. Crassus and Domitius, members, both of them, of the most illustrious families, after holding the consulship, were appointed jointly to the censorship, in the year from the building of the City 662, a period of office that was fruitful in strife, the natural result of their dissimilarity of character. On one occasion, Cneius Domitius, naturally a man of hasty temper, and inflamed besides by a hatred that rivalry only tends to stimulate, gravely rebuked Crassus for living, and he a Censor too, in a style of such magnificence, and in a house for which, as he said, he himself would be ready to pay down ten millions of sesterces. Crassus, a man who united to singular presence of mind great readiness of wit, made answer that, deducting six trees only, he would accept the offer; upon which Domitius replied, that upon those terms he would not give so much as a single denarius for the purchase. “*Well then, Domitius,*” was the rejoinder of Crassus, “which of the two is it that sets a bad example, and deserves the reproof of the censorship; I, who live like a plain man in a house that has come to me by inheritance, or you, who estimate six trees at a value of ten millions of sesterces?” These trees were of the lotus kind, and by the exuberance of their branches afforded a most delightful shade. Cæcina Largus, one of the grandees of Rome, and the owner of the house, used often to point them out to me in my younger days; and, as I have already made mention of the remarkable longevity of trees, I would here add, that they were in existence down to the period when the Emperor Nero set fire

to the City, one hundred and eighty years after the time of Crassus; being still green and with all the freshness of youth upon them, had not that prince thought fit to hasten the death of the very trees even.

Let no one, however, imagine that the house of Crassus was of no value in other respects, or that, from the rebuke of Domitius, there was nothing about it worthy of remark with the exception of these trees. There were to be seen erected in the atrium four columns of marble from Mount Hymettus, which in his ædileship he had ordered to be brought over for the decoration of the stage; and this at a time, too, when no public buildings even as yet possessed any pillars made of that material. Of such recent date is the luxury and opulence which we now enjoy, and so much greater was the value which in those days trees were supposed to confer upon a property! A pretty good proof of which, was the fact that Domitius even, with all his enmity, would not keep to the offer he had made, if the trees were not to be included in the bargain.

The trees have furnished surnames also to the ancients, such, for instance, as that of Fronditius to the warrior who swam across the Volturnus with a wreath of leaves on his head, and distinguished himself by his famous exploits in the war against Hannibal; and that of Stolo to the Licinian family, such being the name given by us to the useless suckers that shoot from trees; the best method of clearing away these shoots was discovered by the first Stolo, and hence his name. The ancient laws also took the trees under their protection; and by the Twelve Tables it was enacted, that he who should wrongfully cut down trees belonging to another person, should pay twenty-five asses for each. Is it possible then to imagine that they, who estimated the fruit-trees at so low a rate as this, could ever have supposed that so exorbitant a value would be put upon the lotus as that which I have just mentioned? And no less marvellous, too, are the changes that have taken place in the value of fruit; for at the present day we find the fruit alone of many of the trees in the suburbs valued at no less a sum than two thousand sesterces; the profits derived from a single tree thus being more than those of a whole estate in former times. It was from motives of gain that the grafting of trees and the propagation thereby of a spurious offspring was first devised, so that the growth of the fruits even might be a thing interdicted to the poor. We shall, therefore, now proceed to state in what way it is that such vast revenues are derived from these trees, and with that object shall set forth the true and most approved methods of cultivation; not taking any notice of the more common methods, or those which we find generally adopted, but considering only those points of doubt and uncertainty, in relation to which practical men are most apt to find themselves at a loss: while, at the same time, to affect any scrupulous exactness in cases where there is no necessity for it, will be no part of our purpose. In the first place, however, we will consider in a general point of view, those influences of soil as well as weather which are exercised upon all the trees in common.

Detailed table of contents

CHAP. 2. (2.)

THE INFLUENCE OF WEATHER UPON THE TREES: WHAT IS THE PROPER SITUATION FOR THE VINE.

Trees are fond of a site more particularly that faces the north-east; the breezes rendering their foliage more thick and exuberant, and imparting additional solidity to the wood. This is a point, however, upon which most people are very greatly deceived; thus in vineyards, for instance, the props ought not to be placed in such a position as to shelter the stems from the wind in that quarter, it being only against the northern blasts that this precaution should be taken. Nay, even more than this — if the cold weather only comes on in due season, it contributes very materially to the strengthening of the trees, and promotes the process of germination; while, on the other hand, if at that period the southern breezes should caress them, they will grow weak and languid, and more particularly so, if the blossom is just coming on. If rainy weather, too, should happen to follow close upon blossoming, the total destruction of the fruit is the necessary result: indeed, if the weather should be only cloudy, or south winds happen to prevail, it is quite sufficient to ensure the loss of the fruit in the almond and the pear. Rains, if prevalent about the rising of the Vergiliæ, are most injurious to the vine and the olive, as it is at that season that germination is commencing with them; indeed, this is a most critical four days for the olive, being the period at which the south wind, as we have already stated, brings on its dark and lowering clouds. The cereals, too, ripen more unfavourably when south winds prevail, though at the same time it proceeds with greater rapidity. All cold, too, is injurious to vegetation, which comes with the northern winds, or out of the proper season. It is most advantageous to all plants for north-east winds to prevail throughout the winter.

In this season, too, showers are very necessary, and the reason is self-evident — the trees, being exhausted by the fruit they have borne, and weakened by the loss of their leaves, are, of course, famished and hungry; and it is the showers that constitute their aliment. Experience has led us to believe that there is nothing more detrimental than a warm winter; for it allows the trees, the moment they have parted with their fruits, to conceive again, or, in other words, to germinate, and then exhaust themselves by blossoming afresh. And what is even worse than this, should there be several years of such weather in succession, even the trees themselves will die; for there can be little doubt that the effort must of necessity be injurious, when they put forth their strength, and are at the same time deprived of their natural sustenance. The poet then, who has said that serene winters are to be desired, certainly did not express those wishes in favour of the trees. And no more does rain, if prevalent at the summer-solstice, conduce to the benefit of the vine: while, at the same time, to say that a dusty winter produces a luxuriant harvest, is

certainly the mistake of a too fertile imagination. It is a thing greatly to be wished, too, both in behalf of the trees as well as the cereals, that the snows should lie for a considerable time upon the ground; the reason being that they check the escape of the spirit of the earth by evaporation, and tend to throw it back again upon the roots of the plants, adding greatly to their strength thereby; and not only this, but they afford a gradual supply of moisture as well, that is both pure and of remarkable lightness, from the fact that snow is only the foam of the waters of heaven. Hence it is that the moisture of snow does not drench and engulph everything all at once, but gradually trickles downwards, in proportion to the thirst of the plant, nurturing it as though from the breast, instead of producing an inundation. The earth, too, ferments under this influence, and becomes filled with her own emanations: not exhausted by the seeds in her bosom, swollen as they are with milk, she smiles in the warm and balmy hours, when the time comes for opening it. It is in this way, more particularly, that corn fattens apace, except, indeed, in those climates in which the atmosphere is always warm, Egypt for example; for there the continuance of the same temperature and the force of habit are productive of the same effects as the modifications of temperature in other countries.

At the same time it is equally necessary in every climate that there should be no noxious influence in existence. Thus, for instance, in the greater part of the world, that precocious germination which has been encouraged by the indulgent temperature of the weather, is sure to be nipped by the intense colds that ensue. Hence it is that late winters are so injurious, and such they prove to the trees of the forest even; indeed, these last are more particularly exposed to the ill effects of a late winter, oppressed as they are by the density of their foliage, and human agency being unable to succour them; for it would be quite impossible to cover the more tender forest trees with wisps of straw. Rains, then, are favourable to vegetation—first of all, during the winter season, and next, just previously to germination; the third period for them being that of the formation of the fruit, though not immediately, and only, in fact, when the produce of the tree shows itself strong and healthy.

Those trees which are the slowest in bringing their fruits to maturity, and require a more prolonged supply of nutriment, receive benefit also from late rains, such as the vine, the olive, and the pomegranate, for instance. These rains, however, are required at different seasons by the different trees, some of them coming to maturity at one period and some at another; hence it is that we see the very same rain productive of injury to some trees and beneficial to others, even when they are of the very same species, as in the pear for instance: for the winter pear stands in need of rain at one period, and the early pear at another, though at the same time they, all of them, require it in an equal degree. Winter precedes the period of germination, and it is this fact that makes the north-east wind more beneficial than the south, and renders the parts that lie in the interior preferable to those near the coast,—the former being generally the coldest,—mountainous districts better than level ones, and rain at

night better than showers in the day. Vegetation, too, receives a greater degree of benefit from the water when the sun does not immediately soak it up.

Connected, too, with this subject is the question of the best situation for planting vines, and the trees which support them. Virgil condemns a western aspect, while there are some persons, again, who prefer it to an easterly one: I find, however, that most authors approve of the south, though I do not think that any abstract precepts can be given in relation to the point. The most careful attention on the part of the cultivator ought to be paid to the nature of the soil, the character of the locality, and the respective influences of climate. The method of giving to the vine a southern aspect, as practised in Africa and * * * is injurious to the tree, as well as unhealthy for the cultivator, from the very circumstance that the country itself lies under a southern meridian: hence it is, that he who selects for his plants there a western or a northerly aspect, will combine on the most advantageous terms the benefits of soil with those of climate. When Virgil condemns a western aspect, there can be no doubt that he includes in his censure a northern aspect as well: and yet, in Cisalpine Italy, where most of the vineyards have an aspect to the north, it has been found by experience that there are none that are more prolific.

The winds are also a very important consideration. In the provinces of Gallia Narbonensis, and in Liguria and part of Etruria, it is considered a proof of great want of skill to plant the vine on a site that lies in the teeth of the wind Circius, while, on the other hand, it is a mark of prudence to catch its breezes in an oblique direction; it is this wind, in fact, that modifies the heat in those countries, though at the same time it is usually so violent, as to sweep away the roofs of the houses.

(3.) There are some persons who employ a method of making the question of weather dependent upon the nature of the soil; thus in the case of a vineyard, for instance, in a dry locality, they give it an eastern or a northern aspect; but where it is planted on a humid site, it is made to face the south. From the varieties of the vine also, they borrow various modifications in reference to site; taking care to plant the early vine in a cold locality, in order that the fruit may ripen before the frosts come on; while such fruit trees and vines as have an antipathy to dews are exposed to the east, that the sun may carry off their humidity at the earliest moment. On the other hand, such as manifest a partiality to dews are planted with a western or even a northern aspect, to give them an opportunity of enjoying them all the longer. Others, again, borrowing their notions pretty nearly from Nature, have recommended that vines and trees should be planted facing the north-east; indeed Democritus is of opinion, that by so doing the fruit will be all the more odoriferous.

(4.) We have already spoken, in the Second Book, of the points of the north-east and other winds, and shall have occasion in the succeeding one to make mention of several more of the heavenly phenomena. In the mean time,

however, we may observe that it would appear to be a manifest proof of the salubrity of a north-east site, that the leaves are always the first to fall in the trees that have an aspect towards the south. A similar reason exists, too, in the maritime districts; in certain localities the sea breezes are detrimental, though in most they are nutritious. For some plants, again, it is pleasant to behold the sea at a distance, while at the same time they will gain nothing by approaching closer to its saline exhalations. The same, too, is the influence exercised by rivers and lakes; they will either scorch the vegetation by the fogs they emit, or else modify by their coolness the excess of heat. We have already mentioned the plants that thrive in the shade, and in the cold even; but in all these matters experience will be found the best of guides.

CHAP. 3.

WHAT SOILS ARE TO BE CONSIDERED THE BEST.

Next after the influences of the heavens, we have to treat of those of the earth, a task that is in no way more easy than the previous one. It is but rarely that the same soil is found suited to trees as well as corn: indeed, the black earth which prevails in Campania is not everywhere found suited to the vine, nor yet that which emits light exhalations, or the red soil that has been so highly praised by many. The cretaceous earth that is found in the territory of Alba Pompeia, and an argillaceous soil, are preferred to all others for the vine, although, too, they are remarkably rich, a quality that is generally looked upon as not suited to that plant. On the other hand, again, the white sand of the district of Ticinum, the black sand of many other places, and the red sand as well, even though mixed with a rich earth, will prove unproductive.

The very signs, also, from which we form our judgment are often very deceptive; a soil that is adorned with tall and graceful trees is not always a favourable one, except, of course, for those trees. What tree, in fact, is there that is taller than the fir? and yet what other plant could possibly exist in the same spot? Nor ought we always to look upon verdant pastures as so many proofs of richness of soil; for what is there that enjoys a greater renown than the pastures of Germany? and yet they consist of nothing but a very thin layer of turf, with sand immediately beneath. Nor yet is the soil which produces herbage of large growth always to be looked upon as humid; no, by Hercules! no more than a soil is to be looked upon as unctuous and rich, which adheres to the fingers — a thing that is proved in the case of the argillaceous earths. The earth when thrown back into the hole from which it has just been dug will never fill it, so that it is quite impossible by that method to form any opinion as to its density or thinness. It is the fact, too, that every soil, without exception, will cover iron with rust. Nor yet can we determine the heaviness or lightness of soils in relation to any fixed and ascertained weight: for what are we to understand as the standard weight of earth? A soil, too, that is formed from the alluvion of rivers is not always to be recommended, for there are some crops that decay all the sooner in a watery soil; indeed, those soils even of this description which are highly esteemed, are never found to be long good for any kind of vegetation but the willow.

Among other proofs of the goodness of soil, is the comparative thickness of the stem in corn. In Laborium, a famous champaign country of Campania, the stalk is of such remarkable thickness, that it may be used even to supply the place of wood: and yet this very soil, from the difficulty that is everywhere experienced in cultivating it, and the labour required in working it, may be almost said to give the husbandman more trouble by its good qualities than it could possibly have done by reason of any defects. The soil, too, that is

generally known as charcoal earth, appears susceptible of being improved by being planted with a poor meagre vine: and tufa, which is naturally rough and friable, we find recommended by some authors. Virgil, too, does not condemn for the vine a soil which produces fern: while a salted earth is thought to be much better entrusted with the growth of vegetation than any other, from the fact of its being comparatively safe from noxious insects breeding there. Declivities, too, are far from unproductive, if a person only knows how to dig them properly; and it is not all champaign spots that are less accessible to the sun and wind than is necessary for their benefit. We have already alluded to the fact, that there are certain vines which find nutriment in hoar frosts and fogs.

In every subject there are certain deep and recondite secrets, which it is left to the intelligence of each to penetrate. Do awe not, for instance, find it the fact, that soils which have long offered opportunities for a sound judgment being formed on their qualities have become totally altered? In the vicinity of Larissa, in Thessaly, a lake was drained; and the consequence was, that the district became much colder, and the olive-trees which had formerly borne fruit now ceased to bear. When a channel was cut for the Hebrus, near the town of Ænos, the place was sensible of its nearer approach, in finding its vines frost-bitten, a thing that had never happened before; in the vicinity, too, of Philippi, the country having been drained for cultivation, the nature of the climate became entirely altered. In the territory of Syracuse, a husbandman, who was a stranger to the place, cleared the soil of all the stones, and the consequence was, that he lost his crops from the accumulation of mud; so that at last he was obliged to carry the stones back again. In Syria again, the plough-share which they use is narrow, and the furrows are but very superficial, there being a rock beneath the soil that in summer scorches up the seeds.

Then, too, the effects of excessive cold and heat in various places are similar; thus, for instance, Thrace is fruitful in corn, by reason of the cold, while Africa and Egypt are so in consequence of the heat that prevails there. At Chalcia, an island belonging to the Rhodians, there is a certain place which is so remarkably fertile, that after reaping the barley that has been sown at the ordinary time, and gathering it in, they immediately sow a fresh crop, and reap it at the same time as the other corn. A gravelly soil is found best suited for the olive in the district of Venafrum, while one of extreme richness is required for it in Bætica. The wines of Pucinum are ripened upon a rock, and the vines of Cæcubum are moistened by the waters of the Pomptine marshes; so great are the differences that have been detected by human experience in the various soils. Cæsar Vopiscus, when pleading a cause before the Censors, said that the fields of Rosia are the very marrow of Italy, and that a stake, left in the ground there one day, would be found covered by the grass the next: the soil, however, is only esteemed there for the purposes of pasturage. Still, however, Nature has willed that we should not remain uninstructed, and has made full

admission as to existing defects in soil, even in cases where she has failed to give us equal information as to its good qualities: we shall begin, therefore, by speaking of the defects that are found in various soils.

(5.) If it is the wish of a person to test whether a soil is bitter, or whether it is thin and meagre, the fact may be easily ascertained from the presence of black and undergrown herbs. If, again, the herbage shoots up dry and stunted, it shows that the soil is cold, and if sad and languid, that it is moist and slimy. The eye, too, is able to judge whether it is a red earth or whether it is argillaceous, both of them extremely difficult to work, and apt to load the harrow or ploughshare with enormous clods; though at the same time it should be borne in mind that the soil which entails the greatest amount of labour is not always productive of the smallest amount of profit. So, too, on the other hand, the eye can distinguish a soil that is mixed with ashes or with white sand, while earth that is sterile and dense may be easily detected by its peculiar hardness, at even a single stroke of the mattock.

Cato, briefly and in his peculiar manner, characterizes the defects that exist in the various soils. "Take care," he says, "where the earth is rotten not to shake it either with carts or by driving cattle over it." Now what are we to suppose that this term "rotten" means, as applied to a soil, about which he is so vastly apprehensive as to almost forbid our setting foot upon it? Let us only form a comparison 'by thinking what it is that constitutes rottenness in wood, and we shall find that the faults which are held by him in such aversion are the being arid, full of holes, rough, white, mouldy, worm eaten, in fact, just like pumice-stone; and thus has Cato said more in a single word than we could have possibly found means to express in a description, however long. Indeed, if we could find means of expressing the various defects that exist in soils, we should find that there are some of them that are old, not with age (for age cannot be concerned in relation to the earth), but of their own nature, and are hence unfruitful and powerless for every purpose from the first. The same writer, too, considers that as the very best of soils, which, situate at the foot of a declivity, runs out into a champaign country, taking a southward direction; such, in fact, being the aspect of the whole of Italy: he says also, that the earth generally known as black earth is of a tender nature, and is consequently the most easily worked and the best for cereals. If we only appreciate with due care the signification of this word "tender," we shall find that it expresses its intended meaning remarkably well, and that in this word is comprised every quality that is desirable for the purposes of cultivation. In a tender soil we shall find fertility combined with moderation, a softness and a pliancy easily adapted to cultivation, and an equal absence of humidity and of dryness. Earth of this nature will shine again after the plough-share has passed through it, just as Homer, that great fountain-head of all genius, has described it sculptured by the Divinity upon the arms [of Achilles], adding, too, a thing that is truly marvellous, that it was of a blackish hue, though gold was the material in which it was wrought. This, too, is that kind of earth, which, when

newly turned up, attracts the ravenous birds that follow the plough-share, the ravens even going so far as to peck at the heels of the ploughman.

We may in this place appropriately make mention of an opinion that has been pronounced by an Italian writer also with reference to a matter of luxury. Cicero, that other luminary of literature, has made the following remark: "Those unguents which have a taste of earth are better," says he, "than those which smack of saffron;" it seeming to him more to the purpose to express himself by the word "taste" than "smell." And such is the fact, no doubt; that soil is the best which has the flavour of a perfume. If the question should be put to us, what is this odour of the earth that is held in such estimation, our answer is, that it is the same that is often to be recognized at the moment of sunset, without the necessity even of turning up the ground, at the spots where the extremities of the rainbow have been observed to meet the earth; as also when, after long-continued drought, the rain has soaked the ground. Then it is that the earth exhales this divine odour, that is so peculiarly its own, and to which, imparted to it by the sun, there is no perfume, however sweet, that can possibly be compared. It is this odour that the earth, when turned up, ought to emit, and which, when once found, can never deceive a person; and this will be found the best criterion for judging of the quality of the soil. Such, too, is the odour that is usually perceived on land newly cleared, when an ancient forest has been just cut down; its excellence is a thing that is universally admitted.

For the culture of the cereals, too, the same land is generally looked upon as the more improved the oftener it has been allowed to rest from cultivation, a thing that is not the case with vineyards; for which reason all the greater care is required in the selection of their site, if we would not have the opinions of those to appear well founded who entertain the notion that the soil of Italy is already worn out. In other kinds of soil the work of cultivation depends entirely upon the weather; as, for instance, in those which cannot be ploughed just after rain, because the natural exuberance of the earth renders it viscous and cloggy. On the other hand, in Byzantium, a district of Africa, and a champaign country of such singular fertility as to render grain one hundred and fifty fold, the soil is such, that in time of drought, not even bulls are able to plough it; while, on another occasion, just after a shower of rain, one poor ass, with an old woman to guide it, is quite sufficient, as ourselves we have witnessed, to do the ploughing. But as to amending one soil by the agency of another, as some persons recommend, by throwing rich earth over one that is poor and thin, or by laying a soaking light soil over one that is humid and unctuous, it is a labour of perfect madness. What can a man possibly hope for who cultivates such a soil as this?

CHAP. 4. (6.)

THE EIGHT KINDS OF EARTH BOASTED OF BY THE GAULS AND GREEKS.

There is another method, which has been invented both in Gaul and Britain, of enriching earth by the agency of itself, being * * * * and that kind known as marl. This soil is looked upon as containing a greater amount of fecundating principles, and acts as a fat in relation to the earth, just as we find glands existing in the body, which are formed by a condensation of the fatty particles into so many kernels. (7.) This mode of proceeding, too, has not been overlooked by the Greeks; indeed, what subject is there that they have not touched upon? They call by the name of leucargillon a white argillaceous earth which is used in the territory of Megara, but only where the soil is of a moist, cold nature.

It is only right that I should employ some degree of care and exactness in treating of this marl, which tends so greatly to enrich the soil of the Gallic provinces and the British islands. There were formerly but two varieties known, but more recently, with the progress of agricultural knowledge, several others have begun to be employed; there being, in fact, the white, the red, the columbine, the argillaceous, the tufaceous, and the sandy marls. It has also one of these two peculiarities, it is either rough or greasy to the touch; the proper mode of testing it being by the hand. Its uses, too, are of a twofold nature — it is employed for the production of the cereals only, or else for the enrichment of pasture land as well. The tufaceous kind is nutrimental to grain, and so is the white; if found in the vicinity of springs, it is fertile to an immeasurable extent; but if it is rough to the touch, when laid upon the land in too large a quantity, it is apt to burn up the soil. The next kind is the red marl, known as *acaunumarga*, consisting of stones mingled with a thin sandy earth. These stones are broken upon the land itself, and it is with considerable difficulty during the earlier years that the stalk of the corn is cut, in consequence of the presence of these stones; however, as it is remarkably light, it only costs for carriage one-half of the outlay required in using the other varieties. It is laid but very thinly on the surface, and it is generally thought that it is mixed with salt. Both of these varieties, when once laid on the land, will fertilize it for fifty years, whether for grain or for hay. (8.) Of the marls that are found to be of an unctuous nature, the best is the white. There are several varieties of it: the most pungent and biting being the one already mentioned. Another kind is the white chalk that is used for cleaning silver; it is taken from a considerable depth in the ground, the pits being sunk, in most instances, as much as one hundred feet. These pits are narrow at the mouth, but the shafts enlarge very considerably in the interior, as is the case in mines; it is in Britain more particularly that this chalk is employed. The good effects of it are found to last full eighty years; and there is no instance known of an

agriculturist laying it twice on the same land during his life. A third variety of white marl is known as glisomarga; it consists of fullers' chalk mixed with an unctuous earth, and is better for promoting the growth of hay than grain; so much so, in fact, that between harvest and the ensuing seed-time there is cut a most abundant crop of grass. While the corn is growing, however, it will allow no other plant to grow there. Its effects will last so long as thirty years; but if laid too thickly on the ground, it is apt to choke up the soil, just as if it had been covered with Signine cement. The Gauls give to the columbine marl in their language the name of eglecopala; it is taken up in solid blocks like stone, after which it is so loosened by the action of the sun and frost, as to split into laminæ of extreme thinness; this kind is equally beneficial for grass and grain. The sandy marl is employed if there is no other at hand, and on moist slimy soils, even when other kinds can be procured.

The Ubii are the only people that we know of, who, having an extremely fertile soil to cultivate, employ methods of enriching it; wherever the land may happen to be, they dig to a depth of three feet, and, taking up the earth, cover the soil with it in other places a foot in thickness; this method, however, to be beneficial, requires to be renewed at the end of every ten years. The Ædui and the Pictones have rendered their lands remarkably fertile by the aid of limestone, which is also found to be particularly beneficial to the olive and the vine. Every marl, however, requires to be laid on the land immediately after ploughing, in order that the soil may at once imbibe its properties; while at the same time, it requires a little manure as well, as it is apt, at first, to be of too acrid a nature, at least where it is not pasture land that it is laid upon; in addition to which, by its very freshness it may possibly injure the soil, whatever the nature of it may be; so much so, indeed, that the land is never fertile the first year after it has been employed. It is a matter of consideration also for what kind of soil the marl is required; if the soil is moist, a dry marl is best suited for it; and if dry, a rich unctuous marl. If, on the other hand, the land is of a medium quality, chalk or columbine marl is the best suited for it.

CHAP. 5. (9.)

THE EMPLOYMENT OF ASHES.

The agriculturists of the parts of Italy beyond the river Padus, are such admirers of ashes for this purpose, that they even prefer it as a manure to the dung of beasts of burden; indeed, they are in the habit of burning dung for this purpose, on account of its superior lightness. They do not, however, use them indiscriminately upon the same soil, nor do they employ ashes for promoting the growth of shrubs, nor, in fact, of some of the cereals, as we shall have occasion to mention hereafter. There are some persons who are of opinion also that dust imparts nutriment to grapes, and cover them with it while they are growing, taking care to throw it also upon the roots of the vines and other trees. It is well known that this is done in the province of Gallia Narbonensis, and it is a fact even better ascertained that the grape ripens all the sooner for it; indeed, the dust there contributes more to its ripeness than the heat of the sun.

CHAP. 6.

MANURE.

There are various kinds of manure, the use of which is of very ancient date. In the times of Homer even, the aged king is represented as thus enriching the land by the labour of his own hands. Tradition reports that King Augeas was the first in Greece to make use of it, and that Hercules introduced the practice into Italy; which country has, however, immortalized the name of its king, Stercutus, the son of Faunus, as claiming the honour of this invention. M. Varro assigns the first rank for excellence to the dung of thrushes kept in aviaries, and lauds it as being not only good for land, but excellent food for oxen and swine as well; indeed, he goes so far as to assert that there is no food that they will grow fat upon more speedily. We really have some reason to augur well of the manners of the present day, if it is true that in the days of our ancestors there were aviaries of such vast extent as to be able to furnish manure for the fields.

Columella gives the second rank to pigeon manure, and the next to that of the poultry-yard; but he condemns that of the aquatic birds. Some authors, again, are agreed in regarding the residue of the human food as the very best of all manures; while others would only employ the superfluous portion of our drink, mixing with it the hair that is to be found in the curriers' workshops. Some, however, are for employing this liquid by itself, though they would mix water with it once more, and in larger quantities even than when originally mixed with the wine at our repasts; there being a double share of noxious qualities to correct, not only those originally belonging to the wine, but those imparted to it by the human body as well. Such are the various methods by which we vie with each other in imparting nutriment to the earth even.

Next to the manures above mentioned, the dung of swine is highly esteemed, Columella being the only writer that condemns it. Some, again, speak highly of the dung of all quadrupeds that have been fed on cytissus, while there are others who prefer that of pigeons. Next to these is the dung of goats, and then of sheep; after which comes that of oxen, and, last of all, of the beasts of burden. Such were the distinctions that were established between the various manures among the ancients, such the precepts that they have left us, and these I have here set forth as being not the mere subtle inventions of genius, but because their utility has been proved in the course of a long series of years. In some of the provinces, too, which abound more particularly in cattle, by reason of their prolific soil, we have seen the manure passed through a sieve like so much flour, and perfectly devoid, through lapse of time, of all bad smell or repulsive look, being changed in its appearance to something rather agreeable than otherwise. In more recent times it has been

found that the olive thrives more particularly in soil that has been manured with the ashes of the lime-kiln. To the ancient rules Varro has added, that corn land should be manured with horsedung, that being the lightest manure of all, while meadow land, he says, thrives better with a manure of a more heavy nature, and supplied by beasts that have been fed upon barley; this last tending more particularly to the better growth of grass. Some persons, indeed, prefer the dung of the beasts of burden to that of oxen even, the manure of the sheep to that of the goat, and the manure of the ass to all others, the reason being that that animal masticates the most slowly of them all. Experience, however, has pronounced against these dicta of Varro and Columella; but it is universally agreed by all writers that there is nothing more beneficial than to turn up a crop of lupines, before they have podded, with either the plough or the fork, or else to cut them and bury them in heaps at the roots of trees and vines. It is thought, also, that in places where no cattle are kept, it is advantageous to manure the earth with stubble or even fern. “ You can make manure,” Cato says, “of litter, or else of lupines, straw, beanstalks, or the leaves of the holm-oak and quercus. Pull up the wallwort from among the crops of corn, as also the hemlock that grows there, together with the thick grass and sedge that you find growing about the willow-plots; of all this, mixed with rotten leaves, you may make a litter for sheep and oxen. If a vine should happen to be but poor and meagre, prune the shoots of it, and plough them in round about it.” The same author says, also, “When you are going to sow corn in a field, fold your sheep there first.”

Detailed table of contents

CHAP. 7.

COPS WHICH TEND TO IMPROVE THE LAND: CROPS WHICH EXHAUST IT.

Cato says, also, that there are some crops which tend to nourish the earth: thus, for instance, corn land is manured by the lupine, the bean, and the vetch; while, on the other hand, the chick-pea exercises a contrary influence, both because it is pulled up by the roots and is of a salt nature; the same is the case, too, with barley, fenugreek, and fitches, all of which have a tendency to burn up corn land, as, in fact, do all those plants which are pulled up by the roots. Take care, too, not to plant stone-fruits on corn land. Virgil is of opinion, also, that corn land is scorched by flax, oats, and poppies.

[Detailed table of contents](#)

CHAP. 8.

THE PROPER MODE OF USING MANURE.

It is recommended, also, that the dung-heap should be kept in the open air, in a spot deep sunk and well adapted to receive the moisture: it should be covered, too, with straw, that it may not dry up with the sun, care being taken to drive a stake of robur into the ground, to prevent serpents from breeding there. It is of the greatest consequence that the manure should be laid upon the land while the west winds prevail, and during a dry moon. Most persons, however, misunderstand this precept, and think this should be done when the west winds are just beginning to blow, and in the month of February only: it being really the fact that most crops require manuring in other months as well. At whatever period, however, it may be thought proper to manure the land, the greatest care should be taken that the wind is blowing due west at the time, and that the moon is on the wane, and quite dry. Such precautions as these will increase in a most surprising degree the fertilizing effects of manure.

CHAP. 9. (10.)

THE MODES IN WHICH TREES BEAR.

Having now treated at sufficient length of the requisite conditions of the weather and the soil, we shall proceed to speak of those trees which are the result of the care and inventive skill of man. Indeed, the varieties of them are hardly less numerous than of those which are produced by Nature, so abundantly have we testified our gratitude in return for her numerous bounties. For these trees, we find, are reared either from seed, or else by transplanting, by layers, by slips torn from the stock, by cuttings, by grafting, or by cutting into the trunk of the tree. But as to the story that the leaves of the palm are planted by the Babylonians, and so give birth to a tree, I am really surprised that Trogus should have ever believed it. Some of the trees are reproduced by several of the methods above enumerated, others, again, by all of them.

Detailed table of contents

CHAP. 10.

PLANTS WHICH ARE PROPAGATED BY SEED.

It is Nature herself that has taught us most of these methods, and more particularly that of sowing seed, as it was very soon evident how the seed on falling to the ground revived again in germination. Indeed, there are some trees that are capable of being propagated in no other way, the chesnut and the walnut, for instance; with the sole exception, of course, of such as are employed for coppice wood. By this method, too, as well as the others, some trees are propagated, though from a seed of a different nature, such, for instance, as the vine, the apple, and the pear; the seed being in all these cases in the shape of a pip, and not the fruit itself, as in that of the chesnut and the walnut. The medlar, too, can also be propagated by the agency of seed. All trees, however, that are grown by this method are very slow in coming to maturity, degenerate very rapidly, and must often be renewed by grafting: indeed, the chesnut even sometimes requires to be grafted.

Detailed table of contents

CHAP. 11.

TREES WHICH NEVER DEGENERATE.

On the other hand, there are some trees which have the property of never degenerating, in whatever manner they are reproduced, the cypress, palm, and laurel, for instance: for we find that the laurel is capable of being propagated in several ways. We have already made mention of the various kinds of laurel; those known as the Augustan, the baccalis, and the tinus are all reproduced in a similar manner. The berries are gathered in the month of January, after they have been dried by the north-east winds which then prevail; they are then kept separate and exposed to the action of the air, being liable to ferment if left in a heap. After this, they are first seasoned with smoke, and then steeped in urine, preparatory to sowing. Some persons put them in baskets of osier, and tread them down with the feet in running water, until the outer skin is removed, as it is found that the moisture which they contain is detrimental to them, and prevents them from germinating. A trench is then dug, about a palm in depth, and somewhere about twenty of the berries are then put into it, being laid in a heap: this is usually done in the month of March. These kinds of laurel admit of being propagated from layers also; but the triumphal laurel can be reproduced from cuttings only.

All the varieties of the myrtle are produced in Campania from the berry only, but at Rome from layers. Democritus, however, says that the Tarentine myrtle may be re-produced another way. They take the largest berries and pound them lightly so as not to crush the pips: with the paste that is thus made a rope is covered, and put lengthwise in the ground; the result of which is that a hedge is formed as thick as a wall, with plenty of slips for transplanting. In the same way, too, they plant brambles to make a hedge, by first covering a rope of rushes with a paste made of bramble-berries. In case of necessity, it is possible at the end of three years to transplant the suckers of the laurel and the myrtle that have been thus re-produced.

With reference to the plants that are propagated from seed, Mago treats at considerable length of the nut-trees—he says that the almond should be sown in a soft argillaceous earth, upon a spot that looks towards the south—that it thrives also in a hard, warm soil, but that in a soil which is either unctuous or moist, it is sure to die, or else to bear no fruit. He recommends also for sowing those more particularly which are of a curved shape like a sickle, and the produce of a young tree, and he says that they should be steeped for three days in diluted manure, or else the day before they are sown in honey and water. He says, also, that they should be put in the ground with the point downwards, and the sharp edge towards the north-east; and that they should be sown in threes and placed triangularly, at the distance of a palm from each other, care being taken to water them for ten days, until such time as they

have germinated.

Walnuts when sown are placed lengthwise, lying upon the sides where the shells are joined; and pine nuts are mostly put, in sevens, into perforated pots, or else sown in the same way as the berries are in the laurels which are reproduced by seed. The citron is propagated from pips as well as layers, and the sorb from seed, by sucker, or by slip: the citron, however, requires a warm site, the sorb a cold and moist one.

Detailed table of contents

CHAP. 12.

PROPAGATION BY SUCKERS.

Nature, too, has taught us the art of forming nurseries; when from the roots of many of the trees we see shooting up a dense forest of suckers, an offspring that is destined to be killed by the mother that has borne them. For by the shade of the tree these suckers are indiscriminately stifled, as we often see the case in the laurel, the pomegranate, the plane, the cherry, and the plum. There are some few trees, the elm and the palm for instance, in which the branches spare the suckers; however, they never make their appearance in any of the trees except those in which the roots, from their fondness for the sun and rain, keep close, as they range, to the surface of the ground. It is usual not to place all these suckers at once in the ground upon the spot which they are finally to occupy, but first to entrust them to the nursery, and to allow them to grow in seed-plots, after which they are finally transplanted. This transplanting softens down, in a most remarkable manner, those trees even which grow wild; whether it is that trees, like men, are naturally fond of novelty and change of scene, or that, on leaving the spots of their original growth, or to which they have been transplanted, they lay aside their bad qualities and become tame, like the wild animals, the moment they are separated from the parent stock.

Detailed table of contents

CHAP. 13.

PROPAGATION BY SLIPS AND CUTTINGS.

Nature has also discovered another method, which is very similar to the last — for slips torn away from the tree will live. In adopting this plan, care should be taken to pull out the haunch of the slip where it adheres to the stock, and so remove with it a portion of the fibrous body of the parent tree. It is in this way that the pomegranate, the hazel, the apple, the sorb, the medlar, the ash, the fig, and more particularly the vine, are propagated. The quince, however, if planted in this way will degenerate, and it has been consequently found a better plan to cut slips and plant them: a method which was at first adopted for making hedges, with the elder, the quince, and the bramble, but came afterwards to be applied to cultivated trees, such as the poplar, the alder, and the willow, which last will grow if even the slip is planted upside down. In the case of cuttings, they are planted at once in the spot which it is intended they should occupy: but before we pass on to the other methods of propagation, it seems as well to mention the care that should be expended upon making seedplots.

Detailed table of contents

CHAP. 14.

SEED-PLOTS.

In laying out a seed-plot it is necessary that a soil of the very highest quality should be selected; for it is very often requisite that a nurse should be provided for the young plants, who is more ready to hamour them than their parent soil. The ground should therefore be both dry and nutritious, well turned up with the mattock, replete with hospitality to the stranger plants, and as nearly as possible resembling the soil to which it is intended they should be transplanted. But, a thing that is of primary importance, the stones must be carefully gathered from off the ground, and it should be walled in, to ensure its protection from the depredations of poultry; the soil too, should have as few chinks and crannies as possible, so that the sun may not be enabled to penetrate and burn up the roots. The young trees should be planted at distances of a foot and a-half; for if they happen to touch one another, in addition to other inconveniences, they are apt to breed worms; for which reason it is that they should be hoed as often as possible, and all weeds pulled up, the young plants themselves being carefully pruned, and so accustomed to the knife.

Cato recommends, too, that hurdles should be set up upon forks, the height of a man, for the purpose of intercepting the rays of the sun, and that they should be covered with straw to keep off the cold. He says that it is in this way that the seeds of the apple and the pear are reared, the pine-nut also, and the cypress, which is propagated from seed as well. In this last, the seed is remarkably small, so much so, in fact, as to be scarcely perceptible. It is a marvellous fact, and one which ought not to be overlooked, that a tree should be produced from sources so minute, while the grains of wheat and of barley are so very much larger, not to mention the bean. What proportion, too, is there between the apple and the pear tree, and the seeds from which they take their rise? It is from such beginnings, too, as these that springs the timber that is proof against the blows of the hatchet, presses that weights of enormous size even are unable to bend, masts that support the sails of ships, and battering-rams that are able to shake even towers and walls! Such is the might, such is the power that is displayed by Nature. But, a marvel that transcends all the rest, is the fact of a vegetable receiving its birth from a tear-like drop, as we shall have occasion to mention in the appropriate place.

To resume, however: the tiny balls which contain the seed are collected from the female cypress — for the male, as I have already stated, is barren. This is done in the months which I have previously mentioned, and they are then dried in the sun, upon which they soon burst, and the seed drops out, a substance of which the ants are remarkably fond; this fact, too, only serves to enhance the marvel, when we reflect that an insect so minute is able to destroy

the first germ of a tree of such gigantic dimensions. The seed is sown in the month of April, the ground being first levelled with rollers, or else by means of rammers; after which the seed is thickly sown, and earth is spread upon it with a sieve, about a thumb deep. If laid beneath a considerable weight, the seed is unable to spring up, and is consequently thrown back again into the earth; for which reason it is often trodden only into the ground. It is then lightly watered after sunset every three days, that it may gradually imbibe the moisture until such time as it appears above ground. The young trees are transplanted at the end of a year, when about three-quarters of a foot in length, due care being taken to watch for a clear day with no wind, such being the best suited for the process of transplanting. It is a singular thing, but still it is a fact, that if, on the day of transplanting, and only that day, there is the slightest drop of rain or the least breeze stirring, it is attended with danger to the young trees; while for the future they are quite safe from peril, though at the same time they have a great aversion to all humidity. The jujube-tree is propagated from seed sown in the month of April. As to the tuber, it is the best plan to graft it upon the wild plum, the quince, and the calabrix, this last being the name that is given to a wild thorn. Every kind of thorn, too, will receive grafts remarkably well from the myxa plum, as well as from the sorb.

(11.) As to recommending transferring the young plants from the seed-plot to another spot before finally planting them out, I look upon it as advice that would only lead to so much unnecessary trouble, although it is most confidently urged that by this process the leaves are sure to be considerably larger than they otherwise would.

Detailed table of contents

CHAP. 15.

THE MODE OF PROPAGATING THE ELM.

The elm seed is collected about the calends of March, before the tree is covered with leaves, but is just beginning to have a yellow tint. It is then left to dry two days in the shade, after which it is thickly sown in a broken soil, earth that has been riddled through a fine sieve being thrown upon it, to the same thickness as in the case of the cypress. If there should happen to be no rain, it is necessary to water the seed. From the nursery the young plants are carried at the end of a year to the elm-plots, where they are planted at intervals of a foot each way. It is better to plant elms in autumn than to support the vine, as they are destitute of seed and are only propagated from plants. In the vicinity of the City, the young elms are transplanted into the vineyard at five years old, or, according to the plan adopted by some, when they are twenty feet in height. A furrow is first drawn for the purpose, the name given to which is “novenarius,” being three feet in depth, and the same in breadth or even more; into this the young tree is put, and the earth is moulded up around it to the height of three feet every way. These mounds are known by the name of “arula” in Campania. The intervals are arranged according to the nature of the spot; but where the country is level, it is requisite that the trees should be planted wider apart. Poplars and ashes, too, as they germinate with greater rapidity, ought to be planted out at an earlier period, or, in other words, immediately after the ides of February. In arranging trees and shrubs for the support of the vine, the form of the quincunx is the one that is generally adopted, and, indeed, is absolutely necessary: it not only facilitates the action of the wind, but presents also a very Pleasing appearance, for whichever way you look at the plantation the trees will always present themselves in a straight Line. The same method is employed in propagating the poplar from seed as the elm, and the mode of transplanting it from the seed-plot is the same as that adopted in transplanting it from the forests.

Detailed table of contents

CHAP. 16.

THE HOLES FOR TRANSPLANTING.

But it is more particularly necessary in transplanting, that the trees should always be removed to a soil that is similar, or else superior, to the one in which they grew before. If taken from warm or early ripening localities, they ought not to be re- moved to cold or backward sites, nor yet, on the other hand, from these last to the former. If the thing can possibly be done, the holes for transplanting should be dug sufficiently long before to admit of their being covered throughout with a thick coat of grass. Mago recommends that they should be dug a whole year beforehand, in order that they may absorb the heat of the sun and the moisture of the showers; or, if circumstances do not admit of this, that fires should be made in the middle of them some two months before transplanting, that being only done just after rain has fallen. He says, too, that in an argillaceous or a hard soil, the proper measurement is three cubits every way, and on declivitous spots one palm more, care being taken in every case to make the hole like the chimney of a furnace, narrower at the orifice than at the bottom. Where the earth is black, the depth should be two cubits and a palm, and the hole dug in a quadrangular form.

The Greek writers agree in pointing out much the same proportions, and are of opinion that the holes ought not to be more than two feet and a half in depth, or more than two feet wide: at the same time, too, they should never be less than a foot and a half in depth, even though the soil should be wet, and the vicinity of water preclude the possibility of the soil going any deeper. "If the soil is watery," says Cato, "the hole should be three feet in width at the orifice, and one palm and a foot at the bottom, and the depth four feet. It should be paved, too, with stones, or, if they are not at hand, with stakes of green willow, or, if these cannot be procured, with a layer of twigs; the depth of the layer so made being a foot and a half."

It appears to me that I ought here to add, after what has been said with reference to the nature of trees, that the holes should be sunk deeper for those which have a tendency to run near the surface of the earth, such as the ash and the olive, for instance. These trees, in fact, and others of a similar nature, should be planted at a depth of four feet, while for the others three feet will be quite sufficient. "Cut down that stump," said Papirius Cursor, the general, when to the great terror of the prætor of Præneste, he had ordered the lictors to draw their axes. And, indeed, there is no harm in cutting away those portions [of the root] which have become exposed. Some persons recommend that a bed should be formed at the bottom, of potsherds or round pebbles, which both allow the moisture to pass and retain as much as is wanted; while at the same time they are of opinion that flat stones are of no use in such a case, and only prevent the root from penetrating the earth. To line the bottom with a

layer of gravel would be to follow a middle course between the two opinions.

Some persons recommend that a tree should not be transplanted before it is two years old, nor yet after three, while others, again, are of opinion that if it is one year old it is quite sufficient; Cato thinks that it ought to be more than five fingers in thickness at the time. The same author, too, would not have omitted, if it had been of any importance, to recommend that a mark should be made on the bark for the purpose of pointing out the southern aspect of the tree; so that, when transplanted, it may occupy exactly the same position that it has previously done; from an apprehension that the north side of the tree, on finding itself opposite to a southern sun, might split, and the south side be nipped by the north-eastern blasts. Indeed, there are some persons who follow a directly opposite practice even in the vine and the fig, by placing the north side of the tree, when transplanted, towards the south, and vice versa; being, of opinion that by adopting this plan the foliage becomes all the thicker and the better able to protect the fruit, which is less liable to fall off in consequence, and that the tree is rendered all the better for climbing. Most people, however, take the greatest care to turn to the south that part of the tree from which the branches have been lopped at the top, little thinking that they expose it thereby to a chance of splitting from the excessive heat. For my own part, I should prefer that this part of the tree should face that point of the heavens which is occupied by the sun at the fifth or even the eighth hour of the day. People are also equally unaware that they ought not, through neglect, to let the roots be exposed to the air long enough to get dry; and that the ground should not be worked about the roots of trees while the wind is blowing from the north, or, indeed, from any point of the heavens that lies between north and southeast; or, at all events, that the roots should not be left to lie exposed to these winds; the result of such modes of proceeding being, that the trees die, the grower being all the while in total ignorance of the cause.

Cato disapproves, too, of all wind and rain whenever the work of transplanting is going on. When this is the case, it will be beneficial to let as much adhere to the roots as possible of the earth in which the tree has grown, and to cover them all round with clods of earth: it is for this reason that Cato recommends that the young trees should be conveyed in baskets, a very desirable method, no doubt. The same writer, too, approves of the earth that has been taken from the surface being laid at the bottom of the hole. Some persons say, that if a layer of stones is placed beneath the root of the pomegranate, the fruit will not split while upon the tree. In transplanting, it is the best plan to give the roots a bent position, but it is absolutely necessary that the tree should be placed in such a manner as to occupy exactly the centre of the hole. The fig-tree, it the slip when planted is stuck in a squill — such being the name of a species of bulb — is said to bear with remarkable rapidity, while the fruit is exempt from all attacks of the worm: the same precaution, too, in planting, will preserve the fruit of all other trees in a

similar manner. Who is there, too, that can entertain a doubt that the very greatest care ought to be taken of the roots of the fig-tree when transplanted? — indeed, it ought to bear every mark of being taken, and not torn, from out of the earth. Upon this subject I omit various other practical precepts, such, for instance, as the necessity of moulding up the roots with a rammer, a thing that Cato looks upon as of primary importance; while, at the same time, he recommends that the wound made in the stock should be first covered with dung, and then bound with a layer of leaves.

[Detailed table of contents](#)

CHAP. 17. (12.)

THE INTERVALS TO BE LEFT BETWEEN TREES.

The present seems to me to be the proper occasion for making some mention of the intervals that ought to be left between the trees. Some persons have recommended that pomegranates, myrtles, and laurels should be planted closer together than the other trees, leaving, however, a space of nine feet between them. Apple-trees, they say, should be planted a little wider apart, and pear-trees, almonds, and figs even still more so. The best rule, however, is to consult the length of the branches, and the nature of the spot, as well as the shade that is formed by the tree; for it is of great importance to take this last into consideration. The shadow thrown by the large trees even is but of small dimensions, when the branches are disposed around the body of the tree in a spherical form, as in the apple and the pear, for instance. In the cherry, on the other hand, and the laurel, the shadow projected is of enormous extent.

Detailed table of contents

CHAP. 18.

THE NATURE OF THE SAD THROWN BY TREES.

The shadows of trees are possessed of certain properties. That of the walnut is baneful and injurious to man, in whom it is productive of head-ache, and it is equally noxious to everything that grows in its vicinity. The shadow, too, of the pine has the effect of killing the grass beneath it; but in both of these trees the foliage presents an effectual resistance to the winds, while, at the same time, the vine is destitute of such protection. The drops of water that fall from the pine, the quercus, and the holm-oak are extremely heavy, but from the cypress none fall; the shadow, too, thrown by this last tree is extremely small, its foliage being densely packed. The shadow of the fig, although widely spread, is but light, for which reason it is allowed to be planted among vines. The shadow of the elm is refreshing and even nutrimental to whatever it may happen to cover; though, in the opinion of Atticus, this tree is one of the most injurious of them all; and, indeed, I have no doubt that such may be the case when the branches are allowed to become too long; but at the same time I am of opinion that when they are kept short it can be productive of no possible harm. The plane also gives a very pleasant shade, though somewhat dense: but in this case we must look more to the luxuriant softness of the grass beneath it than the warmth of the sun; for there is no tree that forms a more verdant couch on which to recline.

The poplar gives no shade whatever, in consequence of the incessant quivering of its leaves: while that of the alder is very dense, but remarkably nutritive to plants. The vine affords sufficient shade for its wants, the leaf being always in motion, and from its repeated movement tempering the heat of the sun with the shadow that it affords; at the same time too it serves as an effectual protection against heavy rains. In nearly all trees the shade is thin, where the footstalks of the leaves are long.

This branch of knowledge is one by no means to be despised or deserving to be placed in the lowest rank, for in the case of every variety of plant the shade is found to act either as a kind nurse or a harsh step-mother. There is no doubt that the shadow of the walnut, the pine, the pitch-tree, and the fir is poisonous to everything it may chance to light upon.

[Detailed table of contents](#)

CHAP. 19.

THE DROPPINGS OF WATER FROM THE LEAVES.

A very few words will suffice for the water that drops from the leaves of trees. In all those which are protected by a foliage so dense that the rain will not pass through, the drops are of a noxious nature. In our enquiries, therefore, into this subject it will be of the greatest consequence what will be the nature developed by each tree in the soil in which we are intending to plant it. Declivities, taken by themselves, require smaller intervals between the trees, and in localities that are exposed to the wind it is beneficial to plant them closer together. However, it is the olive that requires the largest intervals to be left, and on this point it is the opinion of Cato, with reference to Italy, that the very smallest interval ought to be twenty-five feet, and the largest thirty: this, however, varies according to the nature of the site. The olive is the largest of all the trees in Bætica: and in Africa — if, indeed, we may believe the authors who say so — there are many olive-trees that are known by the name of *milliariæ*, being so called from the weight of oil that they produce each year. Hence it is that Mago has prescribed an interval between these trees of no less than seventy-five feet every way, or of forty-five at the very lowest, when the soil happens to be meagre, hard, and exposed to the winds. There is no doubt, however, that Bætica reaps the most prolific harvests from between her olives.

It will be generally agreed that it is a most disgraceful piece of ignorance to lop away the branches more than is absolutely necessary in trees of vigorous growth, and so precipitate old age; as also, on the other hand, what is generally tantamount to an avowal of unskilfulness on the part of those who have planted them, to have to cut them down altogether. Nothing can reflect greater disgrace upon agriculturists than to have to undo what they have done, and it is therefore much the best to commit an error in leaving a superfluity of room.

Detailed table of contents

CHAP. 20. (13.)

TREES WHICH GROW BUT SLOWLY: THOSE WHICH GROW WITH RAPIDITY.

Some trees are naturally slow in their growth; and those in particular which grow solely from seed and are long-lived. On the other hand, those that are short-lived grow with great rapidity, such as the fig, pomegranate, plum, apple, pear, myrtle, and willow, for instance; and yet these are the very first to display their productions, for they begin to bear at three years old, and make some show of it even before that period. The pear is the slowest in bearing of all the trees above enumerated. The cypirus, however, and the shrub known as the pseudo-cypirus are the earliest in coming to maturity, for they flower almost immediately, and then produce their seed. All trees will come to maturity more rapidly when the suckers are removed, and the nutrimental juices are thrown into the stock only.

Detailed table of contents

CHAP. 21.

TREES PROPAGATED FROM LAYERS.

Nature; too, has taught us the art of reproduction from layers. The bramble, by reason of its thinness and the excessive length to which it grows, bends downwards, and throws the extremities of its branches into the earth; these immediately take root again, and would fill every place far and wide, were it not that the arts of cultivation put a check to it; so much so, indeed, that it would almost appear that men are born for nothing else but to take care of the earth. Hence it is, that a thing that is in itself most noxious and most baneful, has taught us the art of reproduction by layers and quicksets. The ivy, too, has a similar property.

Cato says, that in addition to the vine, the fig, as well as the olive, the pomegranate, every variety of the apple, the laurel, the plum, the myrtle, the filbert, the nut of Præste, and the plane, are capable of being propagated by layers.

Layers are of two kinds; in the one, a branch, while still adhering to the tree, is pressed downwards into a hole that measures four feet every way: at the end of two years it is cut at the part where it curves, and is then transplanted at the expiration of three years more. If it is intended to carry the plant to any distance, it is the best plan to place the layer, directly it is taken up, either in an osier basket or any earthen vessel, for its better security when carried. The other mode of reproduction by layers is a more costly one, and is effected by summoning forth a root from the trunk of the tree even. For this purpose, earthen vessels or baskets are provided, and are then well packed with earth; through these the extremities of the branches are passed, and by this mode of encouragement a root is obtained growing amid the fruit itself, and at the very summit of the tree; for it is at the summit that this method is generally adopted. In this way has a bold and daring inventiveness produced a new tree aloft and far away from the ground. At the end of two years, in the manner already stated, the layer is cut asunder, and then planted in the ground, basket and all.

The herb savin is reproduced by layers, as also by slips; it is said, too, that lees of wine or pounded wall-bricks make it thrive wonderfully well. Rosemary also is reproduced in a similar manner, as also from cuttings of the branches; neither savin nor rosemary having any seed. The rhododendrum is propagated by layers and from seed.

CHAP. 22. (14.)

GRAFTING: THE FIRST DISCOVERY OF IT.

Nature has also taught us the art of grafting by means of seed. We see a seed swallowed whole by a famished bird; when softened by the natural heat of the crop, it is voided, with the fecundating juices of the dung, upon some soft couch formed by a tree; or else, as is often the case, is carried by the winds to some cleft in the bark of a tree. Hence it is that we see the cherry growing upon the willow, the plane upon the laurel, the laurel upon the cherry, and fruits of various tints and hues all springing from the same tree at once. It is said, too, that the jack-daw, from its concealment of the seeds of plants in holes which serve as its store-houses, gives rise to a similar result.

[Detailed table of contents](#)

CHAP. 23.

INOCULATION OR BUDDING.

In this, too, the art of inoculating took its rise. By the aid of an instrument similar to a shoe-maker's paring-knife an eye is opened in a tree by paring away the bark, and another bud is then enclosed in it, that has been previously removed with the same instrument from another tree. This was the ancient mode of inoculation with the fig and the apple. That again, described by Virgil, requires a slight fissure to be made in the knot of a bud which has burst through the bark, and in this is enclosed a bud taken from another tree. Thus far has Nature been our instructor in these matters.

[Detailed table of contents](#)

CHAP. 24.

THE VARIOUS KINDS OF GRAFTING.

A different mode of engrafting, however, has been taught us by chance, another great instructor, and one from whom, perhaps, we have learnt a still greater number of lessons. A careful husbandman, being desirous, for its better protection, to surround his cottage with a palisade, thrust the stakes into growing ivy, in order to prevent them from rotting. Seized by the tenacious grasp of the still living ivy, the stakes borrowed life from the life of another wood, and it was found that the stock of a tree acted in place of earth.

For this method of grafting the surface is made level with a saw, and the stock carefully smoothed with the pruning-knife. This done, there are two modes of proceeding, the first of which consists in grafting between the bark and the wood. The ancients were fearful at first of cutting into the wood, but afterwards they ventured to pierce it to the very middle, and inserted the graft in the pith, taking care to enclose but one, because the pith, they thought, was unable to receive more. An improved method has, however, in more recent times, allowed of as many as six grafts being inserted, it being considered desirable by additional numbers to make a provision for the contingency of some of them not surviving. With this view, an incision is carefully made in the middle of the stock, a thin wedge being inserted to prevent the sides from closing, until the graft, the end of which is first cut to a point, has been let into the fissure. In doing this many precautions are necessary, and more particularly every care should be taken that the stock is that of a tree suitable for the purpose, and that the graft is taken from one that is proper for grafting. The sap, too, is variously distributed in the several trees, and does not occupy the same place in all. In the vine and the fig the middle of the tree is the driest, and it is in the summit that the generative power resides; hence it is, that from the top the grafts are selected. In the olive, again, the sap lies in the middle of the tree, and the grafts are accordingly taken from thence: the upper part being comparatively dry. The graft takes most easily in a tree, the bark of which is of a similar nature to its own, and which, blossoming at the same time as itself, has an affinity with it in the development of the natural juices. On the other hand, the process of uniting is but slow where the dry is brought in contact with the moist, and the hard bark with the soft.

The other points to be observed are the following: the incision must not be made in a knot, as such an inhospitable rigidity will certainly repel the stranger plant; the incision should be made, too, in the part which is most compact, and it must not be much more than three fingers in length, not in a slanting direction, nor yet such as to pierce the tree from side to side. Virgil is of opinion, that the grafts should not be taken from the top, and it is universally agreed that it is best to select them from the shoulders of the tree

which look towards the north-east; from a tree, too, that is a good bearer, and from a young shoot, unless, indeed, the graft is intended for an old tree, in which case it should be of a more robust growth. In addition to this, the graft ought to be in a state of impregnation, that is to say, swelling with buds, and giving every promise of bearing the same year; it ought, too, to be two years old, and not thinner than the little finger. The graft is inserted at the smaller end, when it is the object of the grower that it should not grow to any considerable length, but spread out on either side. But it is more particularly necessary that the buds upon the graft should be smooth and regular, and there must be nothing upon it at all scabbed or shrivelled. Success may be fully reckoned on if the pith of the graft is brought in contact with the wood and bark of the stock; that being a much better plan than merely uniting them bark to bark. In pointing the graft, the pith ought not to be laid bare; still, however, it should be pared with a small knife, so that the point may assume the form of a fine wedge, not more than three fingers in length, a thing that may be very easily effected by first steeping it in water and then scraping it. The graft, however, must not be pointed while the wind is blowing, and care must be taken that the bark is not rubbed off from either graft or stock. The graft must be thrust into the stock up to the point where the bark begins; care, too, must be taken not to wrench off the bark during the process of insertion, nor must it be thrust back so as to form any folds or wrinkles. It is for this reason that a graft should not be used that is too full of sap, no, by Hercules! no more than one that is dry and parched; for by doing so, in the former case, from the excess of moisture, the bark becomes detached, and in the latter, from want of vitality, it yields no secretions, and consequently will not incorporate with the stock.

It is a point most religiously observed, to insert the graft during the moon's increase, and to be careful to push it down with both hands; indeed, it is really the fact, that in this operation, the two hands, acting at the same moment, are of necessity productive of a more modified and better regulated effort. Grafts that have been inserted with a vigorous effort are later in bearing, but last all the longer; when inserted more tenderly, the contrary is the result. The incision in the stock should not be too open or too large; nor ought it to be too small, for in such case it would either force out the graft or else kill it by compression. But the most necessary precaution of all is to see that the graft is fairly inserted, and that it occupies exactly the middle of the fissure in the stock.

Some persons are in the habit of making the place for the fissure in the stock with the knife, keeping the edges of the incision together with bands of osier bound tightly round the stock; they then drive in the wedges, the bands keeping the stock from opening too wide. There are some trees that are grafted in the seed-plot and then transplanted the very same day. If the stock used for grafting is of very considerable thickness, it is the best plan to insert the graft between the bark and the wood; for which purpose a wedge made of

bone is best, for fear lest when the bark is loosened the wood should be bruised. In the cherry, the bark is removed before the incision in the stock is made; this, too, is the only tree that is grafted after the winter solstice. When the bark is removed, this tree presents a sort of downy substance, which, if it happens to adhere to the graft, will very speedily destroy it. When once the graft is safely lodged by the aid of the wedge, it is of advantage to drive it home. It is an excellent plan, too, to graft as near the ground as possible, if the conformation of the trunk and knots will admit of it. The graft should not project from the stock more than six fingers in length.

Cato recommends a mixture of argil or powdered chalk, and cow-dung, to be stirred together till it is of a viscous consistency, and then inserted in the fissure and rubbed all round it. From his writings on the subject it is very evident that at that period it was the practice to engraft only between the wood and the bark, and in no other way; and that the graft was never inserted beyond a couple of fingers in depth. He recommends, too, that the pear and the apple should be grafted in spring, as also during fifty days at the time of the summer solstice, and during the time of vintage; but that the olive and the fig should be grafted in spring only, in a thirsting, or in other words, a dry moon: he says also, that it should be done in the afternoon, and not while a south wind is blowing. It is a singular thing, that, not content with protecting the graft in the manner already mentioned, and with sheltering it from showers and frosts by means of turfs and supple bands of split osiers, he recommends that it should be covered with bugloss as well — a kind of herb so called — which is to be tied over it and then covered up with straw. At the present day, however, it is thought sufficient to cover the bark with a mixture of mud and chaff, allowing the graft to protrude a couple of fingers in length.

Those who wait for spring to carry on these operations, will find themselves pressed for time; for the buds are then just bursting, except, indeed, in the case of the olive, the buds of which are remarkably long in developing themselves, the tree itself having extremely little sap beneath the bark; this, too, is apt, when in too large quantities, to injure the grafts. As to the pomegranate, too, the fig, and the rest of the trees that are of a dry nature, it is far from beneficial to them to put off the process of grafting till a late period. The pear may be grafted even when in blossom, so that with it the operation may be safely delayed to the month of May even. If grafts of fruit trees have to be carried to any distance, it is considered the best plan, with the view of preserving the juices, to insert them in a turnip; they may also be kept alive by placing them near a stream or a pond, between two hollow tiles covered up at each end with earth. (15.) The grafts of vines, however, are kept in dry holes, in which they are covered over with straw, and then with earth, care being taken to let the tops protrude.

CHAP. 25.

GRAFTING THE VINE.

Cato speaks of three methods of grafting the vine. The first consists in piercing the stock to the pith, and then inserting the grafts, sharpened at the end, in manner already mentioned, care being taken to bring the pith of the two in contact. The second is adopted in case the two vines are near one another, the sides of them both being cut in a slanting direction where they face each other; after which the pith of the two trees is united by tying them together. In employing the third method, the vine is pierced obliquely to the pith, and grafts are inserted a couple of feet in length; they are then tied down and covered over with prepared earth, care being taken to keep them in an upright position. In our time, however, this method has been greatly improved by making use of the Gallic angler. which pierces the tree without scorching it; it being the fact, that everything that burns the tree weakens its powers. Care, too, is taken to select a graft that is just beginning to germinate, and not to leave more than a couple of the buds protruding from the stock. The vine, too, should be carefully bound with withes of elm, incisions being made in it on either side, in order that the slimy juices may exude through them in preference, which are so particularly injurious to the vine. After this, when the graft has grown a couple of feet, the withe by which it is fastened should be cut, and the graft left to increase of its own natural vigour.

The proper time for grafting the vine has been fixed as from the autumnal equinox to the beginning of the budding season. The cultivated plants are generally grafted on the roots of wild ones, where these last are of a drier nature. But if a cultivated tree should be grafted on a wild one, it will very soon degenerate and become wild. The rest depends entirely on the weather. Dry weather is the best suited for grafting; an excellent remedy for any evil effects that may possibly be caused by the drought, being a few pots of earth placed near the stock and filled with ashes; through which a little water is slowly filtered. Light dews are extremely favourable to grafting by inoculation.

Detailed table of contents

CHAP. 26. (16)

GRAFTING BY SUTCHEONS.

Grafting by scutcheons would appear to owe its origin to that by inoculation; but it is suited more particularly to a thick bark, such as that of the fig-tree for instance. For this purpose, all the branches are cut off, in order that they may not divert the sap, after Which the smoothest part is selected in the stock, and a scutcheon of the bark removed, due care being taken that the knife does not go below it. A similar piece of bark from another tree, with a protuberant bud upon it, is then inserted in its place, care being taken that the union is so exact that there is no room left for a cicatrix to form, and the juncture so perfect as to leave no access to either damp or air: still, however, it is always the best plan to protect the scutcheon by means of a plaster of clay and a band. Those who favour the modern fashions pretend that this method has been only discovered in recent times; but the fact is, that we find it employed by the ancient Greeks, and described by Cato, who recommends it for the olive and the fig; and he goes so far as to determine the very dimensions even, in accordance with his usual exactness. The scutcheon, he says, when taken off with the knife should be four fingers in length, and three in breadth. It is then fitted to the spot which it is to occupy, and anointed with the mixture of his which has been previously described. This method, too, he recommends for the

Some persons have adopted another plan with the vine, which consists partly of that of grafting by scutcheon, and partly by fissure; they first remove a square piece of bark from the stock, and then insert a slip in the place that is thus laid bare. I once saw at Thulix, near Tibur, a tree that had been grafted upon all these various ways, and loaded with fruit of every kind. Upon one branch there were nuts to be seen, upon another berries, upon another grapes, upon another pears, upon another figs, and upon others pomegranates, and several varieties of the apple; the tree, however, was but very short-lived. But, with all our experiments, we find it quite impossible to rival Nature; for there are some plants that can be reproduced in no other manner than spontaneously, and then only in wild and desert spots. The plane is generally considered the best adapted to receive every kind of graft, and next to it the robur; both of them, however, are very apt to spoil the flavour of the fruit. Some trees admit of grafting upon them in any fashion, the fig and the pomegranate for instance; the vine, however, cannot be grafted upon by scutcheon, nor, indeed, any other of the trees which has a bark that is thin, weak, or cracked. So, too, those trees which are dry, or which contain but little moisture, will not admit of grafting by inoculation. This last method is the most prolific of them all, and next to it that by scutcheon, but neither of them can be depended upon, and this last more particularly; for when the adherence of the bark is the only point of union the scutcheon is liable to be

immediately displaced by the slightest gust of wind. Grafting by insertion is the most reliable method, and the tree so produced will bear more fruit than one that is merely planted.

(17.) We must not here omit one very singular circumstance. Corellius, a member of the Equestrian order at Rome, and a native of Ateste, grafted a chesnut, in the territory of Neapolis, with a slip taken from the same tree, and from this was produced the chesnut which is so highly esteemed, and from him has derived its name. At a later period again, Etereius, his freedman, grafted the Corellian chesnut afresh. There is this difference between the two; the Corellian is more prolific, but the Etereian is of superior quality.

CHAP. 27.

PLANTS WHICH GROW FROM A BRANCH.

It is accident that has the credit of devising the other methods of reproduction, and has taught us how to break off a branch of a tree and plant it in the earth, from seeing stakes, when driven in the earth, take root, and grow. It is in this way that many of the trees are reproduced, and the fig more particularly; which may be propagated also by all the methods previously stated, with the exception, indeed, of that by cuttings. The best plan, however, is to take a pretty large branch, and, after sharpening it like a stake, to drive it to a considerable depth in the earth, taking care to leave only a small portion above ground, and then to cover it over with sand. The pomegranate, too, may be planted in a similar manner, the hole being first widened with a stake; the same, too, with the myrtle. For all trees of this nature a branch is required three feet in length, and not quite the thickness of the arm, care being taken to keep the bark on, and to sharpen the branch to a point at the lower end.

Detailed table of contents

CHAP. 28.

TREES WHICH GROW FROM CUTTINGS; THE MODE OF PLANTING THEM.

The myrtle, too, may be propagated from cuttings, and the mulberry is grown no other way, the religious observances relative to lightning forbidding it to be grafted on the elm; hence it would appear that the present is a fitting opportunity for speaking of reproduction from cuttings. Care should be taken more particularly to select the slips from fruitful trees, and it should be seen that they are neither bent, scabbed, nor bifurcated. The cuttings, too, should be thick enough to fill the hand, and not less than a foot in length: the bark, too, should be uninjured, and the end which is cut and lies nearest the root should always be the one inserted in the earth. While the work of germination is going on, the slip should be kept well moulded up, until such time as it has fully taken root.

Detailed table of contents

CHAP. 29. (18.)

THE CULTIVATION OF THE OLIVE.

Cato has treated so well of the precautions that are necessary in cultivating the olive, that we cannot do better than employ his own words on the subject. "Let the slips of olive," says he, "which you are about to plant in the hole, be three feet long, and be very careful in your treatment of them, so as not to injure the bark when you are smoothing or cutting them. Those that you are going to plant in the nursery, should be a foot in length; and you should plant them the following way: let the spot be turned up with the mattock, and the soil be well loosened. When you put the cutting in the ground, press it down with the foot only. If there is any difficulty in making it descend, drive it down with a mallet or the handle of the dibble, but be careful not to break the bark in doing so. Take care, too, not to make a hole first with the dibble, for the slip will have the better chance of surviving the other way. When the slip is three years old, due care must be taken to observe the direction in which each side of the bark is situate. If you are planting in holes or furrows, you must put in the cuttings by threes, but be careful to keep them separate. Above ground, however, they should not be more than four fingers distant from one another, and each of them must have a bud or eye above ground. In taking up the olive for transplanting, you must use the greatest caution, and see that there is as much earth left about the roots as possible. When you have covered the roots well up, tread down the earth with the foot, so that nothing may injure the plant."

Detailed table of contents

CHAP. 30.

TRANSPLANTING OPERATIONS AS DISTRIBUTED THROUGHOUT THE VARIOUS SEASONS OF THE YEAR.

If the enquiry is made what is the proper season for planting the olive, my answer will be, “ where the soil is dry, at seed-time; where it is rich, in spring.” The following is the advice given by Cato on the subject: “Begin pruning your olive-yard fifteen days before the vernal equinox; from that period for forty days will be a good time for doing so. In pruning, adopt the following rules: when the ground is extremely productive, remove all the dry branches or such as may have been broken by the wind; where it is not so prolific, you must cut away still more, then tie them well up, and remove all tangled branches, so as to lighten the roots. In autumn clear away the roots of the olive, and then manure them. The man who labours most assiduously and most earnestly will remove the very smallest fibres that are attached to the roots. If, however, he hoes negligently, the roots will soon appear again above ground, and become thicker than ever; the consequence of which will be, that the vigour of the tree will be expended in the roots.”

We have already stated, when speaking on the subject of oil, what are the different varieties of the olive, in what kind of soil it ought to be planted, and what is the proper aspect for the olive-yard. Mago recommends that the olive should be planted on declivities and in dry spots, in an argillaceous soil, and between autumn and the winter equinox. If, on the other hand, the soil is thick, humid, or somewhat damp even, it ought to be planted between harvest and the winter solstice; advice, however, it should be remembered, applicable to Africa more particularly. At the present day, it is mostly the custom in Italy to plant the olive in spring, but if it is thought desirable to do so in the autumn as well, there are only four days in the forty between the equinox and the setting of the Vergiliæ that are unfavourable for planting it. It is a practice peculiar to Africa, to engraft the olive on the wild olive only, a tree which is made to be everlasting, as it were; for when it becomes old the best of the suckers are carefully trained for adoption by grafting, and in this way in another tree it grows young again; an operation which may be repeated continuously as often as needed; so much so, indeed, that the same olive-yard will last for ages. The wild olive also is propagated both by insertion and inoculation.

It is not advisable to plant the olive in a site where the quercus has been lately rooted up; for the earth-worms, known as “rauæ” which breed in the root of the quercus, are apt to get into that of the olive. It has been found, from practical experience, that it is not advisable to bury the cuttings in the ground nor yet to dry them before they are planted out. Experience has also taught us that it is the best plan to clean an old olive-yard every other year, between the vernal equinox and the rising of the Vergiliæ, and to lay moss about the roots;

to dig holes also round the trees every year, just after the summer solstice, two cubits wide by a foot in depth, and to manure them every third year.

Mago, too, recommends that the almond should be planted between the setting of Arcturus and the winter solstice. All the varieties, however, of the pear, he says, should not be planted at the same time, as they do not all blossom together. Those with oblong or round fruit should be planted between the setting of the Vergiliæ and the winter solstice, and the other kinds in the middle of the winter, after the setting of the constellation of the Arrow, on a site that looks towards the east or north. The laurel should be planted between the setting of the Eagle and that of the Arrow; for we find that the proper time for planting is equally connected with the aspect of the heavenly bodies. For the most part it has been recommended that this should be done in spring and autumn; but there is another appropriate period also, though known to but few, about the rising of the Dog-star, namely; it is not, however, equally advantageous in all localities. Still, I ought not to omit making mention of it, as I am not setting forth the peculiar advantages of any one country in particular, but am enquiring into the operations of Nature taken as a whole.

In the region of Cyrenaica, the planting is generally done while the Etesian winds prevail, and the same is the case in Greece, and with the olive more particularly in Laconia. At this period, also, the vine is planted in the island of Cos; and in the rest of Greece they do not neglect to inoculate and graft, though they do not plant, their trees just then. The natural qualities, too, of the respective localities, exercise a very considerable influence in this respect; for in Egypt they plant in any month, as also in all other countries where summer rains do not prevail, India and Æthiopia, for instance. When trees are not planted in the spring they must be planted in autumn, as a matter of course.

There are three stated periods, then, for germination; spring, the rising of the Dog-star, and that of Arcturus. And, indeed, it is not the animated beings only that are ardent for the propagation of their species, for this desire is manifested in even a greater degree by the earth and all its vegetable productions; to employ this tendency at the proper moment is the most advantageous method of ensuring an abundant increase. These moments, too, are of peculiar importance in relation to the process of grafting, as it is then that the two productions manifest a mutual desire of uniting. Those who prefer the spring for grafting commence operations immediately after the vernal equinox, reckoning on the fact that then the buds are just coming out, a thing that greatly facilitates the union of the barks. On the other hand, those who prefer the autumn graft immediately after the rising of Arcturus, because then the graft at once takes root in some degree, and becomes seasoned for spring, so as not to exhaust its strength all at once in the process of germination. However, there are certain fixed periods of the year, in all cases, for certain trees; thus, the cherry, for instance, and the almond, are either planted or grafted about the winter solstice. For many trees the nature of the locality will be the best guide; thus, where the soil is cold and moist it is best

to plant in spring, and where it is dry and hot, in autumn.

Taking Italy in general, the proper periods for these operations may be thus distributed: — The mulberry is planted at any time between the ides of February and the vernal equinox; the pear, in the autumn, but not beyond the fifteenth day before the winter solstice; the summer apples, the quince, the sorb, and the plum, between mid-winter and the ides of February: the Greek carob and the peach, at any time in autumn before the winter solstice; the various nuts, such as the walnut, pine, filbert, almond, and chesnut, between the calends of March and the ides of that month; the willow and the broom about the calends of March. The broom is grown from seed, and in a dry soil, the willow from plants, in a damp locality, as already stated on former occasions.

(19.) That I may omit nothing to my knowledge of the facts that I have anywhere been able to ascertain, I shall here add a new method of grafting, which has been discovered by Columella, as he asserts, by the aid of which trees even of a heterogeneous or dissociable nature may be made to unite; such, for instance, as the fig and the olive. In accordance with this plan, he recommends that a fig-tree should be planted near an olive, at a distance sufficiently near to admit of the fig being touched by a branch of the olive when extended to its full length; as supple and pliant a one as possible being selected for' the purpose, and due care being taken all the time to render it seasoned by keeping it constantly on the stretch. After this, when the fig has gained sufficient vigour, a thing that generally happens at the end of three or five years at most, the top of it is cut off, the end of the olive branch being also cut to a point in the manner already stated. This point is then to be inserted in the trunk of the fig, and made secure with cords, lest, being bent, it should happen to rebound: in this way we find the method of propagating by layers combined with that of grafting. This union between the two parent trees is allowed to continue for three years, and then in the fourth the branch is cut away and left entirely upon the tree that has so adopted it. This method however, is not at present universally known, at all events, so far as I have been able to ascertain.

Detailed table of contents

CHAP. 31.

CLEANING AND BARING THE ROOTS, AND MOULDING THEM.

In addition to these particulars, the same considerations that I have already mentioned in reference to warm or cold, moist or dry soils, have also taught us the necessity of trenching around the roots. These trenches, however, in a moist, watery soil, should be neither wide nor deep; while the contrary is the case where the ground is hot and dry; it being the object, in the latter instance, to let them receive and retain as much water as possible. This rule is applicable to the culture of old trees as well; for in very hot places the roots are well moulded in summer, and carefully covered up, to prevent the heat of the sun from parching them. In other places, again, the ground is cleared away from the roots, in order to give free access to the air, while in winter they are carefully moulded to protect them from the frost. The contrary is the case, however, in hot climates, for there they bare the roots in winter for the purpose of ensuring a supply of moisture to the parched fibres.

In all places the rule is to make a circular trench three feet in width at the foot of the tree; this, however, it is not possible to do in meadows, where the roots, in their fondness for the sun and showers, range near the surface far and wide. Such, then, are the general observations that we have to make in reference to the planting and grafting of trees that we value for their fruits.

[Detailed table of contents](#)

CHAP. 32. (20.)

WILLOW-BEDS.

It now remains to give an account of those trees which are planted for the sake of others — the vine more particularly — and the wood of which is cut from time to time. Holding the very first rank among these we find the willow, a tree that is always planted in a moist soil. The hole, however, should be two feet and a half in depth, and the slip a foot and a half only in length. Willow stakes are also used for the same purpose, and the stouter they are the better: the distance left between these last should be six feet. When they are three years old their growth is checked by cutting them down within a couple of feet from the ground, the object being to make them spread out, so that by the aid of their branches they may be cleared without the necessity of using a ladder; for the willow is the more productive the nearer its branches are to the ground. It is generally recommended to trench round the willow every year, in the month of April. Such is the mode of cultivation employed for the osier willow.

The stake willow is reproduced both from suckers and cuttings, in a trench of the same dimensions. Stakes may be cut from it at the end of about three years mostly. These stakes are also used to supply the place of the trees as they grow old, being fixed in the ground as layers, and cut away from the trunk at the end of a year. A single jugerum of osier willows will supply osiers sufficient for twenty-five jugera of vines. It is for a similar purpose that the white poplar is grown; the trenches being two feet deep and the cutting a foot and a half in length. It is left to dry for a couple of days before it is planted, and a space is left between the plants a foot and a palm in width, after which they are covered with earth to the depth of a couple of cubits.

[Detailed table of contents](#)

CHAP. 33.

REED-BEDS

The reed requires a soil still moister even than that employed for the willow. It is planted by placing the bulb of the root, that part which some people call the “eye,” in a trench three quarters of a foot in depth, at intervals of two feet and a half. A reed-bed will renew itself spontaneously after the old one has been rooted up, a circumstance which it has been found more beneficial to take advantage of than merely to thin them, as was formerly the practice; the roots being in the habit of creeping and becoming interlaced, a thing that ends eventually in the destruction of the bed. The proper time for planting reeds is before the eyes begin to swell, or, in other words, before the calends of March. The reed continues to increase until the winter solstice but ceases to do so when it begins to grow hard, a sign that it is fit for cutting. It is generally thought, too, that the reed requires to be trenched round as often as the vine.

The reed also is planted in a horizontal position, and then covered with earth to a very great depth; by this method as many plants spring up as there are eyes. It is propagated, also, by planting out in trenches a foot in depth, care being taken to cover up two of the eyes, while a third knot is left just on a level with the ground; the head, too, is bent downwards, that it may not become charged with dew. The reed is usually cut when the moon is on the wane. When required for the vineyard, it is better dried for a year than used in a green state.

OTHER PLANTS THAT ARE CUT FOR POLES AND STAKES.

The chesnut is found to produce better stays for the vine than any other tree, both from the facility with which they are worked, their extremely lasting qualities, and the circumstance that, when cut, the tree will bud again more speedily than the willow even. It requires a soil that is light without being gravelly, a moist, sandy one more particularly, or else a charcoal earth, or a fine tufa even; while at the same time a northern aspect, however cold and shady, and if upon a declivity even, greatly promotes its growth. It refuses to grow, however, in a gravelly soil, or in red earth, chalk, or, indeed, any kind of fertilizing ground. We have already stated, that it is reproduced from the nut, but it will only grow from those of the largest size, and then only when they are sown in heaps of five together. The ground above the nuts should be kept broken from the month of November to February, as it is at that period that the nuts lose their hold and fall of themselves from the tree, and then take root. There ought to be intervals of a foot in width left between them, and the hole in which they are planted should be nine inches every way. At the end of two years or more they are transplanted from this seed plot into another, where they are laid out at intervals of a couple of feet.

Layers are also employed for the reproduction of this tree, and there is none to which they are better adapted: the root of the plant is left exposed, and the layer is placed in the trench at full length, with the summit also protruding from the earth; the result being, that it shoots from the top as well as the root. When transplanted, however, it is very hard to be reconciled, as it stands in dread of all change. Hence it is, that it is nearly two years before it will begin to shoot upward; from which circumstance it is generally preferred to rear the slips in the nursery from the nut itself, to obtaining them from quicksets. The mode of cultivation does not differ from that employed with the plants already mentioned. It is trenched around, and carefully lopped for two successive years; after which it is able to take care of itself, the shade it gives sufficing to stifle all superfluous suckers: before the end of the sixth year it is fit for cutting.

A single jugerum of chesnuts will provide stays for twenty jugera of vineyard, and the branches that are taken from near the roots afford a supply of two-forked uprights; they will last, too, till after the next cutting of the tree.

The æsculus, too, is grown in a similar manner, the time for cutting being three years at the latest. Being less difficult, too, to propagate, it may be planted in any kind of earth, the acorn — and it is only with the æsculus that this is done — being sown in spring, in a hole nine inches in depth, with intervals between the plants of two feet in width. This tree is lightly hoed, four times a year. This kind of stay is the least likely to rot of them all; and the

more the tree is cut, the more abundantly it shoots. In addition to the above, they also grow other trees for cutting that we have already mentioned — the ash for instance, the laurel, the peach, the hazel, and the apple; but then they are of slower growth, and the stays made from them, when fixed in the ground, are hardly able to withstand the action of the earth, and much less any moisture. The elder, on the other hand, which affords stakes of the very stoutest quality, is grown from cuttings, like the poplar. As to the cypress, we have already spoken of it at sufficient length.

CHAP. 35. (21.)

THE CULTURE OF THE VINE AND THE VARIOUS SHRUBS WHICH SUPPORT IT.

Having now described what we may call the armoury of the vine, it remains for us to treat with a particular degree of care of the nature of the vine itself.

The shoots of the vine, as also of certain other trees, the interior of which is naturally of a spongy quality, have certain knots or joints upon the stem that intercept the pith. The intervals between these joints in the branches are short, and more particularly so towards the extremities. The pith, in itself the vivifying spirit of the tree, is always taking an onward direction, so long as the knot, by being open in the centre, allows it a free passage. If, however, the knot should become solidified and deny it a passage, the pith is then thrown downward upon the knot that lies next below it, and making its escape, issues forth there in the shape of a bud, these buds always making their appearance on each side alternately, as already mentioned in the case of the reed and the giant-fennel; in other words, here one bud makes its appearance at the bottom of a knot to the right, the next one takes its place on the left, and so on alternately. In the vine this bud is known as the “gem,” as soon as the pith has formed there a small round knob; but before it has done this, the concavity that is left upon the surface is merely called the “eye:” when situate at the extremity of the shoot, it is known as the “germ.” It is in the same way, too, that the stock branches, suckers, grapes, leaves, and tendrils of the vine are developed: and it is a very surprising fact, that all that grows on the right side of the tree is stronger and stouter than on the left.

Hence it is, that when slips of this tree are planted, it is necessary to cut these knots in the middle, in order to prevent the pith from making its escape. In the same way, too, when planting the fig, suckers are taken, nine inches in length, and after the ground is opened they are planted with the part downwards that grew nearest to the tree, and with a couple of eyes protruding from the earth — in slips of trees, that part is properly called the eye which is to give birth to the: future bud. It is for this reason that, in the seed-plots even the slips that are thus planted sometimes bear the same year the fruit that they would have borne if they had remained upon the tree: this takes place when they have been planted in good seasons and are replete with fecundity, for then they bring to maturity the fruits the conception of which was commenced in another spot. Fig-trees that are thus planted may very easily be transplanted in the third year. As some compensation for the rapidity with which this tree becomes old, it has thus received the privilege of coming to maturity at a very early period.

The vine throws out a great number of shoots. In the first place, however, none of them are ever used for planting, except those which are useless, and would have been cut away as mere brushwood; while, on the other hand,

every part is pruned off that has borne fruit the previous year. In former times, it was the custom to plant the slip with a head at the extremity, consisting of a piece of the hard wood on each side of it, the same, in fact, that is called a mallet shoot at the present day. In more recent times, however, the practice has been adopted of pulling it off merely with a heel attached to it, as in the fig; and there is no kind of slip that takes with greater certainty. A third method, again, has been added to the former ones, and a more simple one as well, that of taking the slip without any heel at all. These slips are known by the name of arrow-shoots, when they are twisted before planting; and the same, when they are neither cut short nor twisted, are called three-budded slips. The same sucker very often furnishes several slips of this kind. To plant a stock-shoot of the vine is unproductive, and, indeed, no shoots will bear unless they are taken from a part that has borne fruit already. A slip that has but few knots upon it, is looked upon as likely not to bear; while a great number of buds is considered an indication of fruitfulness. Some persons say that no suckers ought to be planted, but those which have already blossomed. It is far from advantageous to plant arrow-slips, for after being twisted, they are apt to break in transplanting. The slips when planted should be a foot in length, and not less, and they ought to have five or six knots upon them; with the dimensions above stated, they cannot, however, possibly have less than three buds. It is considered the most advantageous plan to plant them out the same day that they are cut; but if it is found necessary to plant them some time after, they should be kept in the way that we have already mentioned; particular care being taken not to let them protrude from the earth, lest they should become dried by the action of the sun, or nipped by the wind or frost. When they have been kept too long in a dry place, they must be put in water for several days, for the purpose of restoring their verdancy and freshness.

The spot selected, whether for nursery or vineyard, ought to be exposed to the sun, and of as great extent as possible; the soil being turned up to a depth of three feet with a two-pronged fork. The earth, on being thrown up with the mattock, swells naturally, and ridges are formed with it four feet in height, intersected by trenches a couple of feet in depth. The earth in the trenches is carefully cleansed and raked out, so that none of it may be left unbroken, care being taken also to keep it exactly level; if the ridges are unequal, it shows that the ground has been badly dug. At the same time the breadth should be measured of each ridge that lies between the trenches. The slips are planted either in holes or else in elongated furrows, and then covered with very fine earth; but where it is a light soil, the grower will lose his pains should he neglect to place a layer of richer mould beneath. Not less than a couple of slips should be planted together, keeping them exactly on a level with the adjoining earth, which should be pressed down and made compact with the dibble. In the seed-plot there should be intervals left between each two settings a foot and a half in breadth and half a foot in length: when thus planted, it is usual, at the end of two years, to cut the mallet-shoots at the knot

nearest the ground, unless there is some good reason for sparing them. When this is done, they throw out eyes, and with these upon them at the end of three years the quicksets are transplanted.

There is another method, also, of planting the vine, which a luxurious refinement in these matters has introduced. Four mallet-shoots are tightly fastened together with a cord in the greenest part, and when thus arranged are passed through the shank-bone of an ox or else a tube of baked earth, after which they are planted in the ground, care being taken to leave a couple of buds protruding: in this way they become impregnated with moisture, and, immediately on being cut, throw out fresh wood. The tube is then broken, upon which the root, thus set at liberty, assumes fresh vigour, and the clusters ultimately bear upon them grapes belonging to the four kinds thus planted together.

In consequence of a more recent discovery, another method has been adopted. A mallet-shoot is split down the middle and the pith extracted, after which the two portions are fastened together, every care being taken not to injure the buds. The mallet-shoot is then planted in a mixture of earth and manure, and when it begins to throw out branches it is cut, the ground being repeatedly dug about it. Columella assures us that the grapes of this plant will have no stones, but it is a more surprising thing that the slip itself should survive when thus deprived of the pith. Still, however, I think I ought not to omit the fact that there are some slips that grow without the ordinary articulations of trees upon them; thus, for instance, five or six very small sprigs of box if tied together and put in the ground, will take root. It was formerly made a point to take these sprigs from a box-tree that had not been lopped, as it was fancied that in the last case they would not live; experience, however, has since put an end to that notion.

The culture of the vineyard naturally follows the training of the nursery. There are five different kinds of vine: that with the branches running along the ground, the vine that stands without support, the vine that is propped and requires no cross-piece, the vine that is propped and requires a single cross-piece, and the vine that requires a trellis of four compartments. The mode of cultivation requisite for the propped vine may be understood as equally adapted to the one that stands by itself and requires no support, for this last method is only employed where there is a scarcity of wood for stays. The stay with the single cross-piece in a straight line is known by the name of "canterius." It is the best of all for the wine, for then the tree throws no shadow, and the grape is ripened continuously by the sun, while, at the same time, it derives more advantage from the action of the wind, and disengages the dew with greater facility: the superfluous leaves and shoots, too, are more easily removed, and the breaking up of the earth and other operations about the tree are effected with greater facility. But, above all, by the adoption of this method, the tree sheds its blossoms more beneficially than under any other circumstances. This cross-piece is generally made of a stake, or a reed,

or else of a rope of hair or hemp, as is usually the case in Spain and at Brundisium. When the trellis is employed, wine is produced in greater quantities; this method has its name of "compluviata" from the "compluvium" or square opening in the roofs of our houses; the trellis is divided into four compartments by as many crosspieces. This mode of planting the vine will now be treated of, and it will be found equally applicable to every kind, with the only difference that under this last method the operation is somewhat more complicated.

The vine is planted three different ways; in a soil that has been turned up with the spade-the best of the three; in furrows, which is the next best; and in holes, the least advisable method of all: of the way in which ground is prepared by digging, we have made sufficient mention already. (22.) In preparing the furrows for the vine it will be quite sufficient if they are a spade in breadth; but if holes are employed for the purpose, they should be three feet every way. The depth required for every kind of vine is three feet; it should, therefore, be made a point not to transplant any vine that is less than three feet in length, allowing then two buds to be above the ground. It will be necessary, too, to soften the earth by working little furrows at the bottom of the hole, and mixing it up with manure. Where the ground is declivitous, it is requisite that the hole should be deeper, in addition to which it should be artificially elevated on the edge of the lower side. Holes of this nature, which are made a little longer, to receive two vines, are known as "alvei," or beds. The root of the vine should occupy the middle of the hole, and when firmly fixed in the ground it should incline at the top due east; its first support it ought to receive from a reed. The vineyard should be bounded by a decuman path eighteen feet in width, sufficiently wide, in fact, to allow two carts to pass each other; others, again, should run at right angles to it, ten feet in width, and passing through the middle of each jugerum; or else, if the vineyard is of very considerable extent, cardinal paths may be formed instead of them, of the same breadth as the decuman path. At the end, too, of every five of the stays a path should be made to run, or, in other words, there should be one continuous cross-piece to every five stays; each space that is thus included from one end to the other forming a bed.

Where the soil is dense and hard it must be turned up only with the spade, and nothing but quicksets should be planted there; but where, on the other hand, it is thin and loose, mallet-shoots even may be set either in hole or furrow. Where the ground is declivitous it is a better plan to draw furrows across than to turn up all the soil with the spade, so that the falling away of the earth may be counteracted by the position of the cross-pieces. It will be best, too, where the weather is wet or the soil naturally dry, to plant the mallet-shoots in autumn, unless, indeed, there is anything in the nature of the locality to counteract it; for while a dry, hot soil makes it necessary to plant in autumn, in a moist, cold one it may be necessary to defer it until the end of spring even. In a parched soil, too, it would be quite in vain to plant quicksets,

and it is far from advantageous to set mallet-shoots in a dry ground, except just after a fall of rain. On the other hand, in moist localities, a vine in leaf even may be transplanted and thrive very well, and that, too, even as late as the summer solstice, in Spain, for example. It is of very considerable advantage that there should be no wind stirring on the day of planting, and, though many persons are desirous that there should be a south wind blowing at the time, Cato is of quite a different way of thinking.

In a soil of medium quality, it is best to leave an interval of five feet between every two vines; where it is very fertile the distance should be five feet at least, and where it is poor and thin eight at the very most. The Umbri and the Marsi leave intervals between their vines of as much as twenty feet in length, for the purpose of ploughing between them; such a plot of ground as this they call by the name of "porculetum." In a rainy, foggy locality, the plants ought to be set wider apart, but in dry spots nearer to one another. Careful observation has discovered various methods of economizing space; thus, for instance, when a vineyard is planted in shaded ground, a seed-plot is formed there as well; or, in other words, at the same time that the quickset is planted in the place which it is finally to occupy, the mallet-shoot intended for transplanting is set between the vines, as well as between the rows. By adopting this method, each jugerum will produce about sixteen thousand quicksets; and the result is, that two years' fruit is gained thereby, a cutting planted being two years later in bearing than a quickset transplanted. Quicksets, when growing in a vineyard, are cut down at the end of a year, leaving only a single eye above ground; some manure is then placed upon the spot, and a stay driven in close to the plant. In the same manner it is again cut down at the end of the second year, and from this it acquires additional strength, and receives nutriment to enable it to endure the onerous task of reproduction. If this is neglected, in its over-haste to bear it will shoot up slim and meagre, like a bulrush, and from not being subjected to such a training, will grow to nothing but wood. In fact, there is no tree that grows with greater eagerness than the vine, and if its strength is not carefully husbanded for the bearing of fruit, it will be sure to grow to nothing but wood.

The best props for supporting the vine are those which we have already mentioned, or else stays made of the robur and the olive; if these cannot be procured, then props of juniper, cypress, laburnum, or elder, must be employed. If any other wood is used for the purpose, the stakes should be cut at the end each year: reeds tied together in bundles make excellent cross-rails for the vine, and will last as long as five years. Sometimes the shorter stock-branches of the vines are brought together and tied with vine-cuttings, like so many cords: by this method an arcade is formed, known to us by the name of "funetum."

The vine, by the end of the third year, throws out strong and vigorous stock-branches with the greatest rapidity, and these in due time form the tree; after this, it begins to mount the cross-piece. Some persons are in the habit of

“blinding” the vine at this period, by removing the eyes with the end of the pruning-knife turned upwards, their object being to increase the length of the branches — a most injurious practice, however; for it is far better to let the tree become habituated to grow of itself, and to prune away the tendrils every now and then when they have reached the cross-rail, so long as it may be deemed proper to add to its strength. There are some persons who forbid the vine to be touched for a whole year after it has been transplanted, and who say that the pruning-knife ought never to be used before it is five years old; and then at that period they are for cutting it down so completely as to leave three buds only. Others, again, cut down the vine within a year even after it has been transplanted, but then they take care to let the stem increase every year by three or four joints, bringing it on a level with the cross-piece by the fourth. These two methods, however, both of them, retard the fruit and render the tree stunted and knotty, as we see the case in all dwarf trees. The best plan is to make the parent stem as robust and vigorous as possible, and then the wood will be sure to be strong and hardy. It is far from safe, too, to take slips from a cicatrized stem; such a practice is erroneous, and only the result of ignorance. All cuttings of this nature are sure to be the offspring of acts of violence, and not in reality of the tree itself. The vine, while growing, should be possessed of all its natural strength; and we find that when left entirely to itself, it will throw out wood in every part; for there is no portion of it that Nature does not act upon. When the stem has grown sufficiently strong for the purpose, it should at once be trained to the cross-piece; if, however, it is but weak, it should be cut down so as to lie below the hospitable shelter of the cross-piece. Indeed, it is the strength of the stem, and not its age, that ought to decide the matter. It is not advisable to attempt to train a vine before the stem has attained the thickness of the thumb; but in the year after it has reached the frame, one or two stock-branches should be preserved, according to the strength developed by the parent tree. The same, too, must be done the succeeding year, if the weakness of the stem demands it; and in the next, two more should be added. Still, however, there should never be more than four branches allowed to grow; in one word, there must be no indulgence shown, and every exuberance in the tree must in all cases be most carefully repressed; for such is the nature of the vine, that it is more eager to bear than it is to live. It should be remembered, too, that all that is subtracted from the wood is so much added to the fruit. The vine, in fact, would much rather produce shoots and tendrils than fruit, because its fruit, after all, is but a transitory possession: hence it is that it luxuriates to its own undoing, and instead of really gaining ground, exhausts itself.

The nature, too, of the soil will afford some very useful suggestions. Where it is thin and hungry, even though the vine should display considerable vigour, it should be pruned down below the cross-piece and kept there, so that all the shoots may be put forth below it. The interval, however, between the top of the vine and the cross-piece ought to be but very small; so much so, indeed, as

to leave it hopes, as it were, of reaching it, which, however, it must never be suffered to do; for it should never be allowed to recline thereon and spread and run on at its ease. This mode of culture ought, in fact, to be so nicely managed, that the vine should show an inclination rather to grow in body than to run to wood.

The main branch should have two or three buds left below the cross-piece that give promise of bearing wood, and it should be carefully trained along the rail, and drawn close to it in such a manner as to be supported by it, and not merely hang loosely from it. When this is done, it should be tightly fastened also with a binding three buds off, a method which will greatly contribute to check the too abundant growth of the wood, while stouter shoots will be thrown out below the ligature: it is absolutely forbidden, however, to tie the extremity of the main branch. When all this is done, Nature operates in the following way — the parts that are allowed to fall downward, or those which are held fast by the ligature, give out fruit, those at the bend of the branch more particularly. On the other hand, the portion that lies below the ligature throws out wood; by reason, I suppose, of the interception of the vital spirit and the marrow or pith, previously mentioned: the wood, too, that is grown under these circumstances will bear fruit in the following year. In this way there are two kinds of stock branches: the first of which, issuing from the solid stock, gives promise of wood only for this year, and is known as the leaf stock-branch; while that which grows beyond the mark made by the ligature is a fruit stock-branch. There are other kinds, again, that shoot from the stock-branches when they are a year old, and these are in all cases fruit stock-branches. There is left, also, beneath the cross-piece a shoot that is known as the reserve shoot, being always a young stock-branch, with not more than three buds upon it. This is intended to give out wood the next year, in case the vine by over-luxuriance should happen to exhaust itself. Close to it there is another bud left, no bigger than a wart; this is known as the “furunculus,” and is kept in readiness in case the reserve shoot should fail.

The vine, if enticed to bear fruit before the seventh year from its being planted as a slip, will pine away, become as slim as a bulrush, and die. It is thought equally undesirable, too, to let an old stock-branch range far and wide, and extend as far as the fourth stay from the stem; to such a branch the name of dragon-branch is given by some, and of juniculus by others; if these are allowed to spread, they will run to wood only, and make male vines, as they are called. When a vine has become quite hard, it is an extremely bad plan to use it for reproduction by layers. When the vine is five years old the stock-branches are twisted, but each is allowed to throw out some new wood; and so from one to another, care being taken to prune away the old wood. It is always the best plan, however, to leave a reserve shoot; but this should always be very near the main stem of the vine, not at a greater distance, in fact, than that already mentioned. If, too, the stock branches should throw out too luxuriantly, they must be twisted, the object being that the vine may put forth

no more than four secondary branches, or even two only, if it happens to be a single cross-railed vine.

If the vine is to be trained to grow without any stay at all, still it will stand in need, at first, of some support or other, until it has learnt to support itself: in all other respects the mode of proceeding will be the same at first. When pruning, it will be necessary that the thumb-branches should be arranged in equal numbers on either side, in order that the fruit may not overload one side of the tree; and we may here remark by the way, that the fruit by its weight is apt to bear down the tree and counteract any tendency to increase in height. The vine, unsupported, when more than three feet in height, begins to bend, but the others do not, until they are five feet high at the least; care should be taken, however, never to let them exceed the height of a man of moderate stature. Growers are in the habit of surrounding the vines that creep along the ground with a low fence for them to lean upon; and round this fence they dig a trench by way of precaution, for fear lest the branches in their range should meet one another and so come into collision. The greater part of the world, in fact, gather grapes at their vintage, grown in this fashion, and lying upon the ground — at all events, it is so in Africa, Egypt, and Syria; throughout the whole of Asia, too, and in many parts of Europe as well, this method prevails. In such cases the vine ought to be kept down close to the ground, and the root should be nurtured at the same time and in just the same way as in the case of the vine that grows on the cross-piece. Care, too, should be taken to leave only the young thumb-shoots, together with three buds, where it is a prolific soil, two where it is poor and thin: it is better, too, that the shoots should be numerous than individually long. The influences of soil, of which we have made mention already, will make themselves felt all the more powerfully the nearer the grapes grow to the ground.

It is a very advantageous plan to separate the various species of vines and to set them in different compartments — for the mixture of different varieties is apt to deteriorate the flavour not only of the must, but the wine even as well. If, again, for some reason or other, the different kinds must be intermingled, it will be requisite to keep all those together which ripen at exactly the same period. The more fertile and the more level the soil, the higher the cross-pieces must be placed. High cross-pieces, too, are best suited to localities that are subject to heavy dews and fogs, but not to those that are exposed to high winds; on the other hand, where the soil is thin, parched, and arid, or exposed to the wind, the cross-pieces should be set lower. The cross-piece should be fastened to the stay with cords tied as tight as possible, while the bindings used for tying the vine should be thin. As to the various species of vines, and the soils and climates requisite for the growth of each, we have already treated of them, when enumerating the several varieties of the vine and the wines which they produce.

With reference to other points connected with the culture of the vine, there are very considerable doubts. Many persons recommend that the vineyard

should be turned up with the spade after every dew that falls in the summer. Others, again, forbid this practice when the vine is in bud; for the clothes, they say, of the people coming and going to and fro are apt to catch the buds, and either knock or rub them off; it is for this reason, too, that they are so careful to keep all animals away from the vines, those with long wool in particular, as it is very apt to pull off the buds. Raking, too, they say, is very injurious to the vine while the grape is forming; and it will be quite sufficient, they assure us, if the ground is turned up three times in the year, after the vernal equinox — first, at the rising of the Vergiliæ, the second at the rising of the Dog-star, and the third time just as the grape is turning black. Some persons make it a rule that an old vineyard shall have one turning up between the time of vintage and the winter solstice, though others, again, are of opinion that it is quite sufficient to bare the roots and manure them. They turn up the ground again after the ides of April, but before the time for germination, or, in other words, the sixth of the ides of May; then again before the tree begins to blossom, after it has shed its blossom, and, last of all, when the grape is just on the turn. The most skilful growers say that if the ground is dug up oftener than necessary, the grapes will become so remarkably thin-skinned as to burst. When the ground is turned up, care should be taken to do it before the hot hours of the day; a clayey soil, too, should never be ploughed or dug. The dust that is raised in digging is beneficial to the vine, it is said, by protecting it from the heat of the sun and the injurious effects of fogs.

The spring clearing ought to be done, it is universally admitted, within ten days after the ides of May, and before the blossoming begins; in addition to which, it should always be done below the cross-piece. As to the second clearing, opinions differ very considerably. Some think it ought to be done when the blossoming is over, others, again, when the grapes are nearly at maturity. This point, however, may be decided by following the advice of Cato on the subject; for we must now pass on to a description of the proper mode of pruning the vine.

Immediately after the vintage, and while the weather is still warm, the work of pruning begins; this, however, ought never to be done, for certain physical reasons, before the rising of the Eagle, as we shall have occasion to explain in the following Book. Nor should it be done either when the west winds begin to prevail, for even then there is great doubt whether a fault may not be committed by being in too great haste to commence the work. If any return of wintry weather should chance to nip the vines, while still labouring under the wounds recently inflicted on them in pruning, there is little doubt that their buds will become quite benumbed with cold, the wounds will open again, and the eyes, moistened by the juices that distil from the tree, will become frost-bitten by the rigour of the weather. For who is there, in fact, that does not know that the buds are rendered brittle by frost? All this, however, depends upon accurate calculations in the management of large grounds, and the blame of precipitation cannot with any justice be laid upon Nature. The

earlier the vine is pruned, in suitable weather, the greater is the quantity of wood, while the later the pruning, the more abundant is the fruit. Hence it is that it is most advisable to prune the poor meagre vines first, and to defer pruning the more thriving ones to the very last. In pruning, due care should always be taken to cut in a slanting direction, in order that the rain may run off with all the greater facility. The wounds, too, should look downwards towards the ground, and should be made as lightly as possible, the edge of the knife being well-sharpened for the purpose, so as to make a clean cut each time. Care should be taken, too, to cut always between two buds, and that the eyes are not injured in the operation. It is generally thought that wherever the vine is black, all those parts may be cut off, the healthy parts not being touched; as no useful shoots can be put forth by wood that is bad in itself. If a meagre vine has not good stock-shoots, the best plan is to cut it down to the ground, and then to train new ones. In clearing away the leaves, too, those leaves should not be removed which accompany the clusters, for by so doing the grapes are made to fall off, except where the vine happens to be young. Those leaves are regarded as useless which grow on the sides of the trunk and not from an eye; and so, too, are the bunches which shoot from the hard, strong wood, and are only to be removed by the aid of the knife.

Some persons are of opinion that it is a better plan to fix the stay midway between two vines; and, indeed, by the adoption of this method the roots are cleared with greater facility. It is best, however, where the vine needs but a single cross-rail, due care being taken that the rail is a strong one, and the locality not exposed to high winds. In the case of those vines which require trellissed cross-rails, the stay should be placed as near as possible to the burden it has to support; in order, however, that there may be no impediment thrown in the way of clearing the roots, it may be placed at the distance of one cubit from the stock, but not more. It is generally recommended to clear the roots before the pruning is commenced.

Cato gives the following general precepts in relation to the culture of the vine:—"Let the vine grow as high as possible, and fasten it firmly, but not too tight. You should treat it in the following manner. Clean the roots of the vine at seedtime, and after pruning it dig about it, and then begin to labour at the ground, by tracing with the plough continuous furrows every way. Plant the young vines in layers as early as possible, and then break up the ground about them. If the vine is old, take care and prune it as little as possible. In preference, bend the vine into the ground for layers, if necessary, and cut it at the end of two years. The proper time for cutting the young vine, is when it has gained sufficient strength. If the vineyard is bald of vines, then draw furrows between them, and plant quicksets there: but let no shadow be thrown on the furrows, and take care and dig them often. If the vineyard is old, sow ocinum there, in case the trees are meagre: but take care and sow there nothing that bears seed. Put manure, chaff, and grape-husks about the roots, or, indeed, anything of a similar nature that will give the tree additional

strength. As soon as the vine begins to throw out leaves, set about clearing them. Fasten the young trees in more places than one, so that the stem may not break. As soon as it begins to run along the stay, fasten down the young branches lightly, and extend them, in order that they may gain the right position. When the grape begins to be mottled, then tie down the vine. The first season for grafting the vine is the spring, the other when the grape is in blossom; the last period is the best. If it is your wish to transplant an old vine, you will only be able to do so in case it is no thicker than the arm: first, however, you must prune it, taking care not to have more than two buds upon the stem. Then dig it well up by the roots, being careful to trace them, and using every possible precaution not to injure them. Place it in the hole or furrow exactly in the position in which it has stood before, then cover it with earth, which should be well trodden down. You must then prop it up, fasten it, and turn it in the same direction as before; after which, dig about it repeatedly." The ocinum that Cato here recommends to be sown in the vineyards, is a fodder known by that name by the ancients; it thrives in the shade remarkably well, and received its name from the rapidity with which it grows.

(23.) We come now to speak of the method of growing vines upon trees, a mode that has been condemned in the strongest terms by the Saserna's, both father and son, and upheld by Scrofa, these being our most ancient writers on agriculture next to Cato, and men of remarkable skill. Indeed, Scrofa himself will not admit that it is beneficial anywhere except in Italy. The experience of ages, however, has sufficiently proved that the wines of the highest quality are only grown upon vines attached to trees, and that even then the choicest wines are produced by the upper part of the tree, the produce of the lower part being more abundant; such being the beneficial results of elevating the vine. It is with a view to this that the trees employed for this purpose are selected. In the first rank of all stands the elm, with the exception of the Atinian variety, which is covered with too many leaves; and next comes the black poplar, which is valued for a similar reason, being not so densely covered with leaves. Most people, too, by no means hold the ash and the fig in disesteem, as also the olive, if it is not overshadowed with branches. We have treated at sufficient length already of the planting and culture of these several trees.

They must not be touched with the knife before the end of three years; and then the branches are preserved, on each side in its turn, the pruning being done in alternate years. In the sixth year the vine is united to the tree. In Italy beyond the Padus, in addition to the trees already mentioned, they plant for their vines the cornel, the opulus, the linden, the maple, the ash, the yoke-elm, and the quercus; while in Venetia they grow willows for the purpose, on account of the humidity of the soil. The top of the elm is lopped away, and the branches of the middle are regularly arranged in stages; no tree in general being allowed to exceed twenty feet in height. The stories begin to spread out

in the tree at eight feet from the ground, in the hilly districts and upon dry soils, and at twelve in champaign and moist localities. The hand of the trunk ought to have a southern aspect, and the branches that project from them should be stiff and rigid like so many fingers; at the same time due care should be taken to lop off the thin beardlike twigs, in order to check the growth of all shade. The interval best suited for the trees, if it is the grower's intention to keep the soil turned up with the plough, is forty feet back and front, and twenty at the side; if it is not to be turned up, then twenty feet every way will do. A single tree is often made to support as many as ten vines, and the grower is greatly censured who attaches less than three. It is worse than useless to attach the vine before the tree has gained its full strength, as in such case its rapidity of growth would only tend to kill the tree. It is necessary to plant the vine in a trench three feet in depth, leaving an interval of one foot between it and the tree. In this case there is no necessity for using mallet shoots, or for going to any expense in spading or digging; for this method of training on trees has this advantage in particular, that it is beneficial even to the vine that corn should be sown in the same soil; in addition to which, from its height, it is quite able to protect itself, and does not call for the necessity, as in the case of an ordinary vineyard, of enclosing it with walls and hedges or ditches, made at a considerable expense, to protect it from injury by animals.

In the method of training upon trees, reproduction from quicksets or from layers is the only mode employed of all those that have been previously described; the growing by layers being effected two different ways, as already mentioned. The plan, however, of growing from layers in baskets set upon the stages of the tree is the most approved one, as it ensures an efficient protection from the ravages of cattle; while, according to another method, a vine or else a stock-branch is bent into the ground near the tree it has previously occupied, or else the nearest one that may be at liberty. It is recommended that all parts of the parent tree that appear above ground should then be scraped, so that it may not throw out wood; while at the same time there are never less than four buds on the part that is put into the ground for the purpose of taking root; there are also two buds left above ground at the head. The vine intended for training on a tree is planted in a furrow four feet long, three broad, and two and a half in depth. At the end of a year the layer is cut to the pith, to enable it to strengthen gradually at the root; after which, the end of the branch is pruned down to within two buds from the ground. At the end of two years the layer is completely separated from the stock, and buried deeper in the ground, that it may not shoot at the place where it has been cut. As to the quicksets, they ought to be removed directly after the vintage.

In more recent times, a plan has been discovered of planting a dragon branch near the tree — that being the name given to an old stock-branch that has become hard and tough in the course of years. For this purpose, it is cut as long as possible, and the bark is taken off from three-fourths of its length, that being the portion which is to be buried in the ground; hence it is, too, that it is

called a “barked” plant. It is then laid at full length in the furrow, the remaining part protruding from the ground and reclining against the tree. This method is the most speedy one that can be adopted for growing the vine. If the vine is meagre or the soil impoverished, it is usual to keep it cut down as near to the ground as possible, until such time as the root is strengthened. Care, too, should be taken not to plant it covered with dew, nor yet while the wind is blowing from the north. The vine itself ought to look towards the north-east, but the young stock-shoots should have a southern aspect.

There should not be too great haste in pruning a young vine, but a beginning should be made by giving the wood and foliage a circular form, care being taken not to prune it until it has become quite strong; it should be remembered, too, that the vine, when trained upon a tree, is generally a year later in bearing fruit than when grown on the cross-piece. There are some persons, again, who altogether forbid that a vine should be pruned until such time as it equals the tree in height. At the first pruning it may be cut to within six feet from the ground, below which a shoot must be left, and encouraged to run out by bending the young wood. Upon this shoot, when pruned, there should not be more than three buds left. The branches that take their rise from these buds should be trained in the following year upon the lowermost stages of the tree, and so in each successive year taught to climb to the higher ones. Care, too, should always be taken to leave one hard, woody branch at each stage, as well as one breeding shoot, at liberty to mount as high as it pleases. In addition to these precautions, in all pruning, those shoots should be cut off which have borne fruit the last year, and after the ten- drills have been cut away on every side fresh branches should be trained to run along the stages. In Italy the pruning is so managed that the shoots and tendrils of the vines are arranged so as to cover the branches of the tree, while the shoots of the vine in their turn are surrounded with clusters of grapes. In Gallia, on the other hand, the vine is trained to pass from tree to tree. On the Æmilian Way, again, the vine is seen embracing the trunks of the Atinian elms that line the road, while at the same time it carefully avoids their foliage.

It is a mark of ignorance in some persons to suspend the vine with a cord beneath the branches of the tree, to the great risk of stifling it; for it ought to be merely kept up with a withe of osier, and not tightly laced. Indeed, in those places where the willow abounds, the withes that it affords are preferred, on account of their superior suppleness, while the Sicilians employ for the purpose a grass, which they call “ampelodesmos:” throughout the whole of Greece, rushes, cyperus, and sedge are similarly employed. When at any time the vine has been liberated from its bonds, it should be allowed to range uncontrolled for some days, and to spread abroad at pleasure, as well as to recline upon the ground which it has been looking down upon the whole year through. For in the same manner that beasts of burden when released from the yoke, and dogs when they have returned from the chase, love to roll themselves on the ground, just so does the vine delight to stretch its loins. The

tree itself, too, seems to rejoice, and, thus relieved from the continuous weight which has burdened it, to have all the appearance of now enjoying a free respiration. Indeed, there is no object in all the economy of Nature that does not desire certain alternations for the enjoyment of rest, witness the succession of night and day, for instance. It is for this reason that it is forbidden to prune the vine directly the vintage is over, and while it is still exhausted by the process of reproduction.

Directly the vine has been pruned, it ought to be fastened again to the tree, but in another place; for there is no doubt that it feels very acutely the indentations that are made in it by the holdfasts. In the Gallic method of cultivation they train out two branches at either side, if the trees are forty feet apart, and four if only twenty; where they meet, these branches are fastened together and made to grow in unison; if, too, they are anywhere deficient in number or strength, care is taken to fortify them by the aid of small rods. In a case, however, where the branches are not sufficiently long to meet, they are artificially prolonged by means of a hook, and so united to the tree that desires their company. The branches thus trained to unite they used to prime at the end of the second year. But where the vine is aged, it is a better plan to give them a longer time to reach the adjoining tree, in case they should not have gained the requisite thickness; besides which, it is always good to encourage the growth of the hard wood in the dragon branches.

There is yet another method, which occupies a middle place between this mode of propagation and that by layers. It consists of laying the entire vine in the earth, and then splitting the stock asunder by means of wedges; the fibrous portions are then trained out in as many furrows, care being taken to support each of the slender plants by fastening it to a stake, and not to cut away the branches that shoot from the sides. The growers of Novara, not content with the multitude of shoots that run from tree to tree, nor yet with an abundance of branches, encourage the stock-branches to entwine around forks planted in the ground for the purpose; a method, however, which, in addition to the internal defects arising from the soil, imparts a harshness to the wine.

There is another fault, too, that is committed by the people of Varracina, near Rome—they only prune their vines every other year; not, indeed, because it is advantageous to the tree, but from a fear lest, from the low prices fetched by their wines, the expense might exceed the profits. At Carseoli they adopt a middle course, by pruning away only the rotten parts of the vine, as well as those which are beginning to wither, and leaving the rest to bear fruit, after thus clearing away all superfluous incumbrances. The only nutriment they give it is this exemption from frequent pruning; but unless the soil should happen to be a very rich one, the vine, under such a method of cultivation, will very soon degenerate to a wild state.

The vine that is thus trained requires the ground to be ploughed very deep, though such is not the case for the sowing there of grain. It is not customary to cut away the leaves in this case, which, of course, is so much labour spared.

The trees themselves require pruning at the same period as the vine, and are thinned by clearing away all useless branches, and such parts as would only absorb the nutriment. We have already stated that the parts that are lopped should never look north or south: and it will be better still, if they have not a western aspect. The wounds thus made are very susceptible for a considerable time, and heal with the greatest difficulty, if exposed to excesses of cold or heat. The vine when trained on a tree enjoys advantages that are not possessed by the others; for the latter have certain fixed aspects, .while in the former, it is easy to cover up the wounds made in pruning, or to turn them whichever way you please. When trees are pruned at the top, cup-like cavities should be formed there, to prevent the water from lodging.

CHAP. 36.

HOW GRAPES ARE PROTECTED FROM THE RAVAGES OF INSECTS.

Stays, too, should be given to the vine for it to take hold of and climb upwards, if they are taller than it. (24.) Espaliers for vines of a high quality should be cut, it is said, at the Quinquatria, and when it is intended to keep the grapes, while the moon is on the wane. We are assured, moreover, that those which are cut at the change of the moon, are exempt from the attacks of all insects. According to another system, it is said that vines should be pruned by night at full moon, and while it is in Leo, Scorpio, Sagittarius, or Taurus: and that, in general, they ought to be planted either when the moon is at full or on the increase. In Italy, ten workmen will suffice for one hundred jugera of vineyard.

CHAP. 37.

THE DISEASES OF TREES.

Having now treated sufficiently at length of the planting and cultivation of trees — (for we have already said enough of the palm and the cytissus, when speaking of the exotic trees) — we shall proceed, in order that nothing may be omitted, to describe other details relative to their nature, which are of considerable importance, when taken in connection with all that precedes. Trees, we find, are attacked by maladies; and, indeed, what created thing is there that is exempt from these evils? Still however, the affections of the forest trees, it is said, are not attended with danger to them, and the only damage they receive is from hail-storms while they are budding and blossoming; with the exception, indeed, of being nipped either by heat or cold blasts in unseasonable weather; for frost, when it comes at the proper times, as we have already stated, is serviceable to them. “Well but,” it will be said, “is not the vine sometimes killed with cold?” No doubt it is, and this it is through which we detect inherent faults in the soils, for it is only in a cold soil that the vine will die. Just in the same way, too, in winter we approve of cold, so long as it is the cold of the weather, and not of the ground. It is not the weakest trees, too, that are endangered in winter by frost, but the larger ones. When they are thus attacked, it is the summit that dries away the first, from the circumstance that the sap becomes frozen before it is able to arrive there.

Some diseases of trees are common to them all, while others, again, are peculiar to individual kinds, Worms are common to them all, and so, too, is sideration, with pains in the limbs, which are productive of debility in the various parts. Thus do we apply the names of the maladies that prevail among mankind to those with which the plants are afflicted. In the same way, too, we speak of their bodies being mutilated, the eyes of the buds being burnt up, with many other expressions of a similar nature. It is in accordance with the same phraseology that we say that trees are afflicted with hunger or indigestion, both of which result from the comparative amount of sap that they contain; while some, again, are troubled with obesity, as in the case of all the resinous trees, which, when suffering from excessive fatness, are changed into a torch-tree. When the roots, too, begin to wax fat, trees, like animals, are apt to perish from excess of fatness. Sometimes, too, a pestilence will prevail in certain classes of trees, just as among men, we see maladies attack, at one time the slave class, and at another the common people, in cities or in the country, as the case may be.

Trees are more or less attacked by worms; but still, nearly all are subject to them in some degree, and this the birds are able to detect by the hollow sound produced on tapping at the bark. These worms even have now begun to be looked upon as delicacies by epicures, and the large ones found in the robur

are held in high esteem; they are known to us by the name of "cossis;" and are even fed with meal, in order to fatten them! But it is the pear, the apple, and the fig that are most subject to their attacks, the trees that are bitter and odoriferous enjoying a comparative exemption from them. Of those which infest the fig, some breed in the tree itself, while others, again, are produced by the worm known as the cerastes; they all, however, equally assume the form of the cerastes, and emit a small shrill noise. The service-tree is infested, too, with a red hairy worm, which kills it; and the medlar, when old, is subject to a similar malady.

The disease known as sideration entirely depends upon the heavens; and hence we may class under this head, the ill effects produced by hail-storms, carbunculation, and the damage caused by hoar-frosts. When the approach of spring tempts the still tender shoots to make their appearance, and they venture to burst forth, the malady attacks them, and scorches up the eyes of the buds, filled as they are with their milky juices: this is what upon flowers they call "charcoal" blight. The consequences of hoar-frost to plants are even more dangerous still, for when it has once settled, it remains there in a frozen form, and there is never any wind to remove it, seeing that it never prevails except in weather that is perfectly calm and serene. Sideration, however, properly so called, is a certain heat and dryness that prevails at the rising of the Dog-star, and owing to which grafts and young trees pine away and die, the fig and the vine more particularly. The olive, also, besides the worm, to which it is equally subject with the fig, is attacked by the measles, or as some think fit to call it, the fungus or platter; it is a sort of blast produced by the heat of the sun. Cato says that the red moss is also deleterious to the olive. An excessive fertility, too, is very often injurious to the vine and the olive. Scab is a malady common to all trees. Eruptions, too, and the attacks of a kind of snail that grows on the bark, are diseases peculiar to the fig, but not in all countries; for there are some maladies that are prevalent in certain localities only.

In the same way that man is subject to diseases of the sinews, so are the trees as well, and, like him, in two different ways. Either the virulence of the disease manifests itself in the feet, or, what is the same thing, the roots of the tree, or else in the joints of the fingers, or, in other words, the extremities of the branches that are most distant from the trunk. The parts that are thus affected become dry and shrivel up: the Greeks have appropriate names by which to distinguish each of these affections. In either case the first symptoms are that the tree is suffering from pain, and the parts affected become emaciated and brittle; then follows rapid consumption and ultimately death; the juices being no longer able to enter the diseased parts, or, at all events, not circulating in them. The fig is more particularly liable to this disease: but the wild fig is exempt from all that we have hitherto mentioned. Scab is produced by viscous dews which fall after the rising of the Vergiliæ; but if they happen to fall copiously, they drench the tree, without making the bark rough. When the fig is thus attacked, the fruit falls off while green; and so, too, if there is

too much rain. The fig suffers also from a superfluity of moisture in the roots.

In addition to worms and sideration, the vine is subject to a peculiar disease of its own, which attacks it in the joints, and is produced from one of the three following causes: — either the destruction of the buds by stormy weather, or else the fact, as remarked by Theophrastus, that the tree, when pruned, has been cut with the incisions upwards, or has been injured from want of skill in the cultivator. All the injury that is inflicted in these various ways is felt by the tree in the joints more particularly. It must be considered also as a species of sideration, when the cold dews make the blossoms fall off, and when the grapes harden before they have attained their proper size. Vines also become sickly when they are perished with cold, and the eyes are frost-bitten just after they have been pruned. Heat, too, out of season, is productive of similar results: for everything is regulated according to a fixed order and certain determinate movements. Some maladies, too, originate in errors committed by the vine-dresser; when they are tied too tight, for instance, as already mentioned, or when in trenching round them the digger has struck them an unlucky blow, or when in ploughing about them the roots have been strained through carelessness, or the bark has been stripped from off the trunk: sometimes, too, contusions are produced by the use of too blunt a pruning-knife. Through all the causes thus enumerated the tree is rendered more sensitive to either cold or heat, as every injurious influence from without is apt to concentrate in the wounds thus made. The apple, however, is the most delicate of them all, and more particularly the one that bears the sweetest fruit. In some trees weakness induced by disease is productive of barrenness, and does not kill the tree; as in the pine for instance, or the palm, when the top of the tree has been removed; for in such case the tree becomes barren, but does not die. Sometimes, too, the fruit itself is sickly, independently of the tree; for example, when there is a deficiency of rain, or of warmth, or of wind, at the periods at which they usually prevail, or when, on the other hand, they have prevailed in excess; for in such cases the fruit will either drop off or else deteriorate. But the worst thing of all that can befall the vine or the olive, is to be pelted with heavy showers just when the tree is shedding its blossom, for then the fruit is sure to fall off as well.

Rain, too, is productive of the caterpillar, a noxious insect that eats away the leaves, and, some of them, the blossoms as well; and this in the olive even, as we find the case at Miletus; giving to the half-eaten tree a most loathsome appearance. This pest is produced by the prevalence of a damp, languid heat; and if the sun should happen to shine after this with a more intense heat and burn them up, this pest only gives place to another just as bad, the aspect only of the evil being changed.

There is still one other affection that is peculiar to the olive and the vine, known as the “cobweb,” the fruit being enveloped in a web, as it were, and so stifled. There are certain winds, too, that are particularly blighting to the olive and the vine, as also to other fruits as well: and then besides, the fruits

themselves, independently of the tree, are very much worm-eaten in some years, the apple, pear, medlar, and pomegranate for instance. In the olive the presence of the worm may be productive of a twofold result: if it grows beneath the skin, it will destroy the fruit, but if it is in the stone, it will only gnaw it away, making the fruit all the larger. The prevalence of showers after the rising of Arcturus prevents them from breeding; but if the rains are accompanied with wind from the south, they will make their appearance in the ripe fruit even, which are then very apt to fall. This happens more particularly in moist, watery localities; and even if they do not fall, the olives that are so affected are good for nothing. There is a kind of fly also that is very troublesome to some fruit, acorns and figs for instance: it would appear that they breed from the juices secreted beneath the bark, which at this period are sweet. These trees, too, are generally in a diseased state when this happens.

There are certain temporary and local influences which cause instantaneous death to trees, but which cannot properly be termed diseases; such, for example, as consumption, blast, or the noxious effects of some winds that are peculiar to certain localities; of this last nature are the Atabulus that prevails in Apulia, and the Olympias of Eubœa. This wind, if it happens to blow about the winter solstice, nips the tree with cold, and shrivels it up to such a degree that no warmth of the sun can ever revive it. Trees that are planted in valleys, and are situate near the banks of rivers, are especially liable to these accidents, the vine more particularly, the olive, and the fig. When this has been the case, it may instantly be detected the moment the period for germination arrives, though, in the olive, somewhat later. With all of these trees, if the leaves fall off, it is a sign that they will recover; but if such is not the case, just when you would suppose that they have escaped uninjured, they die. Sometimes, however, the leaves will become green again, after being dry and shrivelled. Other trees, again, in the northern regions, Pontus and Phrygia, for example, suffer greatly from cold or frost, in case they should continue for forty days after the winter solstice. In these countries, too, as well as in other parts, if a sharp frost or copious rains should happen to come on immediately after fructification, the fruit is killed in a very few days even.

Injuries inflicted by the hand of man are productive also of bad effects. Thus, for instance, pitch, oil, and grease, if applied to trees, and young ones more particularly, are highly detrimental. They may be killed, also, by removing a circular piece of the bark from around them, with the exception, indeed, of the cork-tree, which is rather benefitted than otherwise by the operation; for the bark as it gradually thickens tends to stifle and suffocate the tree: the andrachle, too, receives no injury from it, if care is taken not to cut the body of the tree. In addition to this, the cherry, the lime, and the vine shed their bark; not that portion of it, indeed, which is essential to life, and grows next the trunk, but the part that is thrown off, in proportion as the other grows beneath. In some trees the bark is naturally full of fissures, the plane for instance: in the linden it will all but grow again when removed. Hence, in

those trees the bark of which admits of cicatrization, a mixture of clay and dung is employed by way of remedy; and sometimes with success, in case excessive cold or heat does not immediately supervene. In some trees, again, by the adoption of these methods death is only retarded, the robur and the quercus, for example. The season of the year has also its peculiar influences; thus, if the bark is removed from the fir and the pine, while the sun is passing through Taurus or Gemini, the period of their germination, they will instantly die, while in winter they are able to withstand the injurious effects of it much longer: the same is the case, too, with the holm-oak, the robur, and the quercus. In the trees above mentioned, if it is only a narrow circular strip of bark that is removed, no injurious effects will be perceptible; but in the case of the weaker trees, as well as those which grow in a thin soil, the same operation, if performed even on one side only, will be sure to kill them. The removal of the top, in the pitch-tree, the cedar, and the cypress is productive of a similar result; for if it is either cut off or destroyed by fire, the tree will not survive: the same is the case, too, if they are bitten by the teeth of animals.

Varro informs us, too, as we have already stated, that the olive, if only licked by a she-goat, will be barren. When thus injured, some trees will die, while in others the fruit becomes deteriorated, the almond, for instance, the fruit of which changes from sweet to bitter. In other cases, again, the tree is improved even — such, for instance, as the pear known in Chios as the Phocian pear. We have already mentioned certain trees, also, that are all the better for having the tops removed. Most trees perish when the trunk is split; but we must except the vine, the apple, the fig, and the pomegranate. Others, again, will die if only a wound is inflicted: the fig, however, as well as all the resinous trees, is proof against such injury. It is far from surprising that, when the roots of a tree are cut, death should be the result; most of them perish, however, when, not all the roots, but only the larger ones, and those which are more essential to life, have been severed.

Trees, too, will kill one another by their shade, or the density of their foliage, as also by the withdrawal of nourishment. Ivy, by clinging to a tree, will strangle it. The mistletoe, too, is far from beneficial, and the cytissus is killed by the plant to which the Greeks have given the name of halimon. It is the nature of some plants not to kill, but to injure, by the odour they emit, or by the admixture of their juices; such is the influence exercised by the radish and the laurel upon the vine. For the vine may reasonably be looked upon as possessed of the sense of smell, and affected by odours in a singular degree; hence, when it is near a noxious exhalation, it will turn away and withdraw from it. It was from his observation of this fact that Androcydes borrowed the radish as his antidote for drunkenness, recommending it to be eaten on such occasions. The vine, too, abhors all coleworts and garden herbs, and the hazel as well; indeed it will become weak and ailing if they are not removed to a distance from it. Nitre, alum, warm sea-water, and the shells of beans and fitches act as poisons on the vine.

CHAP. 38. (25.)

PRODIGIES CONNECTED WITH TREES.

Among the maladies which affect the various trees, we may find room for portentous prodigies also. For we find some trees that have never had a leaf upon them; a vine and a pome-granate bearing fruit adhering to the trunk, and not upon the shoots or branches; a vine, too, that bore grapes but had no leaves; and olives that have lost their leaves while the fruit remained upon the tree. There are some marvels also connected with trees that are owing to accident; an olive that was completely burnt, has been known to revive, and in Bœotia, some fig-trees that had been quite eaten away by locusts budded afresh. Trees, too, sometimes change their colour, and turn from black to white; this, however, must not always be looked upon as portentous, and more particularly in the case of those which are grown from seed; the white poplar, too, often becomes black. Some persons are of opinion also that the service-tree, if transplanted to a warmer locality, will become barren. But it is a prodigy, no doubt, when sweet fruits become sour, or sour fruits sweet; and when the wild fig becomes changed into the cultivated one, or vice versa. It is sadly portentous, too, when the tree becomes deteriorated by the change, the cultivated olive changing into the wild, and the white grape or fig becoming black: such was the case, also, when upon the arrival of Xerxes there, a plane-tree at Laodicea was transformed into an olive. In such narratives as these, the book written in Greek by Aristander abounds, not to enter any further on so extended a subject; and we have in Latin the Commentaries of C. Epidius, in which we find it stated that trees have even been known to speak. In the territory of Cumæ, a tree, and a very ominous presage it was, sank into the earth shortly before the civil wars of Pompeius Magnus began, leaving only a few of the branches protruding from the ground. The Sibylline Books were accordingly consulted, and it was found that a war of extermination was impending, which would be attended with greater carnage the nearer it should approach the city of Rome.

Another kind of prodigy, too, is the springing up of a tree in some extraordinary and unusual place, the head of a statue, for instance, or an altar, or upon another tree even. A fig-tree shot forth from a laurel at Cyzicus, just before the siege of that city; and so in like manner, at Tralles, a palm issued from the pedestal of the statue of the Dictator Cæsar, at the period of his civil wars. So, too, at Rome, in the Capitol there, in the time of the wars against Perseus, a palm-tree grew from the head of the statue of Jupiter, a presage of impending victory and triumphs. This palm, however, having been destroyed by a tempest, a fig-tree sprang up in the very same place, at the period of the lustration made by the censors M. Messala and C. Cassius, a time at which, according to Piso, an author of high authority, all sense of shame had been

utterly banished. Above all the prodigies, however, that have ever been heard of, we ought to place the one that was seen in our own time, at the period of the fall of the Emperor Nero, in the territory of Marrucinum; a plantation of olives, belonging to Vectius Marcellus, one of the principal members of the Equestrian order, bodily crossed the public highway, while the fields that lay on the opposite side of the road passed over to supply the place which had been thus vacated by the olive-yard.

CHAP. 39. (26.)

TREATMENT OF THE DISEASES OF TREES.

Having set forth the various maladies by which trees are attacked, it seems only proper to mention the most appropriate remedies as well. Some of these remedies may be applied to all kinds of trees in common, while others, again, are peculiar to some only. The methods that are common to them all, are, baring the roots, or moulding them up, thus admitting the air or keeping it away, as the case may be; giving them water, or depriving them of it, refreshing them with the nutritious juices of manure, and lightening them of their burdens by pruning. The operation, too, of bleeding, as it were, is performed upon them by withdrawing their juices, and the bark is scraped all round to improve them. In the vine, the stock branches are sometimes lengthened out, and at other times repressed; the buds too are smoothed, and in a measure polished up, in case the cold weather has made them rough and scaly. These remedies are better suited to some kinds of trees and less so to others: thus the cypress, for instance, has a dislike to water, and manifests an aversion to manure, spading round it, pruning, and, indeed, remedial operations of every kind; nay, what is more, it is killed by irrigation, while, on the other hand, the vine and the pomegranate receive their principal nutriment from it. In the fig, again, the tree is nourished by watering, while the very same thing will make the fruit pine and die: the almond, too, if the ground is spaded about it, will lose its blossom. In the same way, too, there must be no digging about the roots of trees when newly grafted, or indeed until such time as they are sufficiently strong to bear. Many trees require that all superfluous burdens should be pruned away from them, just as we ourselves cut the nails and hair. Old trees are often cut down to the ground, and then shoot up again from one of the suckers; this, however, is not the case with all of them, but only those, the nature of which, as we have already stated, will admit of it.

Detailed table of contents

CHAP. 40.

METHODS OF IRRIGATION.

Watering is good for trees during the heats of summer, but injurious in winter; the effects of it are of a varied nature in autumn, and depend upon the peculiar nature of the soil. Thus, in Spain for instance, the vintager gathers the grapes while the ground beneath is under water; on the other hand, in most parts of the world, it is absolutely necessary to carry off the autumn rains by draining. It is about the rising of the Dog-star that irrigation is so particularly beneficial; but even then it ought not to be in excess, as the roots are apt to become inebriated, and to receive injury therefrom. Care should be taken, too, to proportion it to the age of the tree, young trees being not so thirsty as older ones; those too which require the most water, are the ones that have been the most used to it. On the other hand, plants which grow in a dry soil, require no more moisture than is absolutely necessary to their existence.

Detailed table of contents

CHAP. 41.

REMARKABLE FACTS CONNECTED WITH IRRIGATION.

In the Fabian district, which belongs to the territory of Sulmo in Italy, where they are in the habit, also, of irrigating the fields, the natural harshness of the wines makes it necessary to water the vineyards; it is a very singular thing, too, that the water there kills all the weeds, while at the same time it nourishes the corn, thus acting in place of the weeding- hook. In the same district, too, at the winter solstice, and more particularly when the snow is on the ground or frosts prevail, they irrigate the land, a process which they call “warming” the soil. This peculiarity, however, exists in the water of one river only, the cold of which in summer is almost insupportable.

Detailed table of contents

CHAP. 42. (27.)

-INCISIONS MADE IN TREES.

The proper remedies for charcoal-blight and mildew will be pointed out in the succeeding Book. In the meantime, however, we may here observe that among the remedies may be placed that by scarification. When the bark becomes meagre and impoverished by disease, it is apt to shrink, and so compress the vital parts of the tree to an excessive degree: upon which, by means of a sharp pruning knife held with both hands, incisions are made perpendicularly down the tree, and a sort of looseness, as it were, imparted to the skin. It is a proof that the method has been adopted with success, when the fissures so made remain open and become filled with wood of the trunk growing between the lips.

Detailed table of contents

CHAP. 43.

OTHER REMEDIES FOR THE DISEASES OF TREES.

The medical treatment of trees in a great degree resembles that of man, seeing that in certain cases the bones of them both are perforated even. The bitter almond will become sweet, if, after spading round the trunk and cleaning it, the lowermost part of it is pierced all round, so that the humours may have a passage for escape and ensure being removed. In the elm, too, the superfluous juices are drawn off, by piercing the tree above ground to the pith when it is old, or when it is found to suffer from an excess of nutriment. So, too, when the bark of the fig is turgid and swollen, the confined juices are discharged by means of light incisions made in a slanting direction; by the adoption of which method the fruit is prevented from falling off. When fruit-trees bud but bear no fruit, a fissure is made in the root, and a stone inserted; the result of which is, that they become productive. The same is done also with the almond, a wedge of robur being employed for the purpose. For the pear and the service tree a wedge of torch-wood is used, and then covered over with ashes and earth. It is even found of use, too, to make circular incisions around the roots of the vine and fig, when the vegetation is too luxuriant, and then to throw ashes over the roots. A late crop of figs is ensured, if the first fruit is taken off when green and little larger than a bean; for it is immediately succeeded by fresh, which ripens at a later period than usual. If the tops of each branch are removed from the fig, just as it is beginning to put forth leaves, its strength and productiveness are greatly increased. As to caprification, the effect of that is to ripen the fruit.

Detailed table of contents

CHAP. 44.

CAPRIFICATION, AND PARTICULARS CONNECTED WITH THE FIG.

It is beyond all doubt that in caprification the green fruit gives birth to a kind of gnat; for when they have taken flight, there are no seeds to be found within the fruit: from this it would appear that the seeds have been transformed into these gnats. Indeed, these insects are so eager to take their flight, that they mostly leave behind them either a leg or a part of a wing on their departure. There is another species of gnat, too, that grows in the fig, which in its indolence and malignity strongly resembles the drone of the beehive, and shows itself a deadly enemy to the one that is of real utility; it is called *centrina*, and in killing the others it meets its own death.

Moths, too, attack the seeds of the fig: the best plan of getting rid of them, is to bury a slip of mastich, turned upside down, in the same trench. The fig, too, is rendered extremely productive by soaking red earth in *amurca*, and laying it, with some manure, upon the roots of the tree, just as it is beginning to throw out leaves. Among the wild figs, the black ones, and those which grow in rocky places, are the most esteemed, from the fact of the fruit containing the most seed. Caprification takes place most advantageously just after rain.

Detailed table of contents

CHAP. 45.

ERRORS THAT MAY BE COMMITTED IN PRUNING.

But, before everything, especial care should be taken that intended remedies are not productive of ill results; as these may arise from either remedial measures being applied in excess or at unseasonable times. Clearing away the branches is of the greatest benefit to trees, but to slaughter them this way every year, is productive of the very worst results. The vine is the only tree that requires lopping every year, the myrtle, the pomegranate, and olive every other; the reason being that these trees shoot with great rapidity. The other trees are lopped less frequently, and none of them in autumn; the trunk even is never scraped, except in spring. In pruning a tree, all that is removed beyond what is absolutely necessary, is so much withdrawn from its vitality.

Detailed table of contents

CHAP. 46.

THE PROPER MODE OF MANURING TREES.

The same precautions, too, are to be regarded in manuring. Though manure is grateful to the tree, still it is necessary to be careful not to apply it while the sun is hot, or while it is too new, or more stimulating than is absolutely necessary. The dung of swine will burn up the vine, if used at shorter intervals than those of five years; unless, indeed, it is mixed with water. The same is the case, too, with the refuse of the currier's workshop, unless it is well diluted with water: manure will scorch also, if laid on land too plentifully. It is generally considered the proper proportion, to use three modii to every ten feet square; this, however, the nature of the soil must decide.

Detailed table of contents

CHAP. 47.

-MEDICAMENTS FOR TREES.

Wounds and incisions of trees are treated also with pigeon dung and swine manure. If pomegranates are acid, the roots of the tree are cleared, and swine's dung is applied to them: the result is, that in the first year the fruit will have a vinous flavour, but in the succeeding one it will be sweet. Some persons are of opinion that the pomegranate should be watered four times a year with a mixture of human urine and water, at the rate of an amphora to each tree; or else that the extremities of the branches should be sprinkled with silphium steeped in wine. The stalk of the pomegranate should be twisted, if it is found to split while on the tree. The fig, too, should be drenched with the amurca of olives, and other trees when they are ailing, with lees of wine; or else lupines may be sown about the roots. The water, too, of a decoction of lupines is beneficial to the fruit, if poured upon the roots of the tree. When it thunders at the time of the Vulcanalia, the figs fall off; the only remedy for which is to have the area beneath ready covered with barley-straw. Lime applied to the roots of the tree makes cherries come sooner to maturity, and ripen more rapidly. The best plan, too, with the cherry, as with all other kinds, is to thin the fruit, so that that which is left behind may grow all the larger.

(28.) There are some trees, again, which thrive all the better for being maltreated, or else are stimulated by pungent substances; the palm and the mastich for instance, which derive nutriment from salt water. Ashes have the same virtues as salt, only in a more modified degree; for which reason it is, that fig-trees are sprinkled with them; as also with rue, to keep away worms, and to prevent the roots from rotting. What is still more even, it is recommended to throw salt water on the roots of vines, if they are too full of humours; and if the fruit falls off, to sprinkle them with ashes and vinegar, or with sandarach if the grapes are rotting. If, again, a vine is not productive, it should be sprinkled and rubbed with strong vinegar and ashes; and if the grapes, instead of ripening, dry and shrivel up, the vine should be lopped near the roots, and the wound and fibres drenched with strong vinegar and stale urine; after which, the roots should be covered up with mud annealed with these liquids, and the ground spaded repeatedly.

As to the olive, if it gives promise of but little fruit, the roots should be bared, and left exposed to the winter cold, a mode of treatment for which it is all the better.

All these operations depend each year upon the state of the weather, and require to be sometimes retarded, and at other times precipitated. The very element of fire even has its own utility, in the case of the reed for instance; which, after the reed-bed has been burnt, will spring up all the thicker and

more pliable.

Cato, too, gives receipts for certain medicaments, specifying the proportions as well; for the roots of the large trees he prescribes an amphora, and for those of the smaller ones, an urna, of amphora of olives, mixed with water in equal proportions, recommending the roots to be cleared, and the mixture to be gradually poured upon them. In addition to this, in the case of the olive and the fig, he recommends that a layer of straw should be first placed around them. In the fig, too, more particularly, he says that in spring the roots should be well moulded up; the result of which is, that the fruit will not fall off while green, and the tree will be all the more productive, and not affected with roughness of the bark. In the same way, too, to prevent the vine-fretter from attacking the tree, he recommends that two congi of amurca of olives should be boiled down to the consistency of honey, after which it must be boiled again with one-third part of bitumen, and one-fourth of sulphur; and this should be done, he says, in the open air, for fear of its igniting if prepared in-doors; with this mixture, the vine is to be anointed at the ends of the branches and at the axils; after which, no more fretters will be seen. Some persons are content to make a fumigation with this mixture while the wind is blowing towards the vine, for three days in succession.

Many persons, again, attribute no less utility and nutritious virtue to urine than Cato does to amurca; only they add to it an equal proportion of water, it being injurious if employed by itself. Some give the name of “volucres” to an insect which eats away the young grapes: to prevent this, they rub the pruning-knife, every time it is sharpened, upon a beaver-skin, and then prune the tree with it: it is recommended also, that after the pruning, the knife should be well rubbed with the blood of a bear. Ants, too, are a great pest to trees; they are kept away, however, by smearing the trunk with red earth and tar: if a fish, too, is hung up in the vicinity of the tree, these insects will collect in that one spot. Another method, again, is to pound lupines in oil, and anoint the roots with the mixture. Many people kill both ants as well as moles with amurca, and preserve apples from caterpillars as well as from rotting, by touching the top of the tree with the gall of a green lizard.

Another method, too, of preventing caterpillars, is to make a woman, with her monthly courses on her, go round each tree, barefooted and ungirt. Again, for the purpose of preventing animals from doing mischief by browsing upon the leaves, they should be sprinkled with cow-dung each time after rain, the showers having the effect of washing away the virtues of this application.

The industry of man has really made some very wonderful discoveries, and, indeed, has gone so far as to lead many persons to believe, that hail-storms may be averted by means of a certain charm, the words of which I really could not venture seriously to transcribe; although we find that Cato has given those which are employed as a charm for sprained limbs, employing splints of reed in conjunction with it. The same author, too, has allowed of consecrated trees and groves being cut down, after a sacrifice has first been

offered: the form of prayer, and the rest of the proceedings, will be found fully set forth in the same work of his.

SUMMARY. — Remarkable facts, narratives; and observations, eight hundred and eighty.

ROMAN AUTHORS QUOTED. — Cornelius Nepos, Cato the Censor, M. Varro, Celsus, Virgil, virginus, Saserna father and son, Scrofa, Calpurnius Bassus, Trogus, Æmilius Macer, Græcinus, Columella, Atticus Julius, Fabianus, Mamilius Sura, Dossenus Mundus, C. Epidius, L. Piso.

FOREIGN AUTHORS QUOTED. — Hesiod, Theophrastus, Aristotle, Democritus, Theopompus, King Hiero, King Attalus Philometor, King Archelaus, Archytas, Xenophon, Amphilochous of Athens, Anaxipolis of Thasos, Apollodorus of Lemnos, Aristophanes of Miletus, Antigonus of Cymæ, Agathocles of Chios, Apollonius Pergamus, Bacchius of Miletus, Bion of Soli, Chæreus of Athens, Chæristus of Athens, Diodorus of Priene, Dion of Colophon, Epigenes of Rhodes, Euagon of Thasos, Euphronius of Athens, Androtion who wrote on Agriculture, Æschryon who wrote on Agriculture, Lysimachus who wrote on Agriculture, Dionysius who translated Mago, Diophanes who made an Epitome of Dionysius, Aristander who wrote on Portents.

BOOK XVIII. THE NATURAL HISTORY OF GRAIN.

Detailed table of contents

CHAP. 1. (1.)

TASTE OF THE ANCIENTS FOR AGRICULTURE.

WE now pass on to the Natural History of the various grains, of the garden plants and flowers, and indeed of all the other productions, with the exception of the trees and shrubs, which the Earth, in her bounteousness, affords us — a boundless field for contemplation, if even we regard the herbs alone, when we take into consideration the varieties of them, their numbers, the flowers they produce, their odours, their colours, their juices, and the numerous properties they possess — all of which have been engendered by her with a view to either the preservation or the gratification of the human race.

On entering, however, upon this branch of my subject, it is my wish in the first place to plead the cause of the Earth, and to act as the advocate of her who is the common parent of all, although in the earlier part of this work I have already had occasion to speak in her defence. For my subject matter, as I proceed in the fulfillment of my task, will now lead me to consider her in the light of being the producer of various noxious substances as well; in consequence of which it is that we are in the habit of charging her with our crimes, and imputing to her a guilt that is our own. She has produced poisons, it is true; but who is it but man that has found them out? For the birds of the air and the beasts of the field, it is sufficient to be on their guard against them, and to keep at a distance from them. The elephant, we find, and the gurus, know how to sharpen and renovate their teeth against the trunks of trees, and the rhinoceros against rocks; wild boars, again, point their tusks like so many poniards by the aid of both rocks and trees; and all animals, in fact, are aware how to prepare themselves for the infliction of injury upon others; but still, which is there among them all, with the exception of man, that dips his weapons in poison? As for ourselves, we envenom the point of the arrow, and we contrive to add to the destructive powers of iron itself; by the aid of poisons we taint the waters of the stream, and we infect the various elements of Nature; indeed, the very air even, which is the main support of life, we turn into a medium for the destruction of life.

And it is not that we are to suppose that animals are ignorant of these means of defence, for we have already had occasion to point out the preparations which they make against the attacks of the serpent, and the methods they devise for effecting a cure when wounded by it; and yet, among them all, there is not one that fights by the aid of the poison that belongs to another, with the sole exception of man. Let us then candidly confess our guilt, we who are not contented even with the poisons as Nature has produced them; for by far the greater portion of them, in fact, are artificially prepared by the human hand!

And then besides, is it not the fact, that there are many men, the very

existence of whom is a baneful poison, as it were? Like that of the serpent, they dart their livid tongue, and the venom of their disposition corrodes every object upon which it concentrates itself. Ever vilifying and maligning, like the ill-omened birds of the night, they disturb the repose of that darkness which is so peculiarly their own, and break in upon the quiet of the night even, by their moans and wailings, the only sounds they are ever heard to emit. Like animals of inauspicious presage, they only cross our path to prevent us from employing our energies or becoming useful to our fellow-men; and the only enjoyment that is sought by their abominable aspirations is centred in their universal hatred of mankind.

Still, however, even in this respect Nature has asserted her majestic sway; for how much more numerous are the good and estimable characters which she has produced! just in the same proportion that we find her giving birth to productions which are at once both salutary and nutritious to man. It is in our high esteem for men such as these, and the commendations they bestow, that we shall be content to leave the others, like so many brakes and brambles, to the devouring flames of their own bad passions, and to persist in promoting the welfare of the human race; and this, with all the more energy and perseverance, from the circumstance that it has been our object throughout, rather to produce a work of lasting utility than to ensure ourselves a widely-spread renown. We have only to speak, it is true, of the fields and of rustic operations; but still, it is upon these that the enjoyment of life so materially depends, and that the ancients conferred the very highest rank in their honors and commendations.

[Detailed table of contents](#)

CHAP. 2. (2.)

WHEN THE FIRST WREATHS OF CORN WERE USED AT ROME.

Romulus was the first who established the Arval priesthood at Rome. This order consisted of the eleven sons of Accra Placentia, his nurse, together with Romulus himself, who assumed the appellation of the twelfth of the brotherhood. Upon this priesthood he bestowed, as being the most august distinction that he could confer upon it, a wreath of ears of corn, tied together with a white fillet; and this in fact, was the first chaplet that was ever used at Rome. This dignity is only ended with life itself, and whether in exile or in captivity, it always attends its owner. In those early days, two jugera of land were considered enough for a citizen of Rome, and to none was a larger portion than this allotted. And yet, at the present day, men who but lately were the slaves of the Emperor Nero have been hardly content with pleasure-gardens that occupied the same space as this; while they must have fishponds, forsooth, of still greater extent, and in some instances I might add, perhaps, kitchens even as well.

Numa first established the custom of offering corn to the gods, and of propitiating them with the salted cake; he was the first, too, as we learn from Hemina, to parch spelt, from the fact that, when in this state, it is more wholesome as an aliment. This method, however, he could only establish one way: by making an enactment, to the effect that spelt is not in a pure state for offering, except when parched. He it was, too, who instituted the Fornacalia, festivals appropriated for the parching of corn, and others, observed with equal solemnity, for the erection and preservation of the “termini,” or boundaries of the fields: for these termini, in those days, they particularly regarded as gods; while to other divinities they gave the names of Seia, from “sero,” “to sow,” and of Segesta, from the “segetes,” or “crops of standing corn,” the statues of which goddesses we still see erected in the Circus. A third divinity it is forbidden by the rules of our religion to name even beneath a roof. In former days, too, they would not so much as taste the corn when newly cut, nor yet wine when just made, before the priests had made a libation of the first-fruits.

Detailed table of contents

CHAP. 3. (3.

THE JUGERUM OF LAND.

That portion of land used to be known as a “jugerum,” which was capable of being ploughed by a single “jugum,” or yoke of oxen, in one day; an “actus” being as much as the oxen could plough at a single spell, fairly estimated, without stopping. This last was one hundred and twenty feet in length; and two in length made a jugerum. The most considerable recompense that could be bestowed upon generals and valiant citizens, was the utmost extent of land around which a person could trace a furrow with the plough in a single day. The whole population, too, used to contribute a quarter of a sextarius of spelt, or else half a one, per head.

From agriculture the earliest surnames were derived. Thus, for instance, the name of Pilumnus was given to him who invented the “pilum,” or pestle of the bake-house, for pounding corn; that of Piso was derived from “piso,” to grind corn; and those of Fabius, Lentulus, and Cicero, from the several varieties of leguminous plants in the cultivation of which respectively these individuals excelled. One individual of the family of the Junii received the name of “Bubuleus,” from the skill he displayed in breeding oxen. Among the sacred ceremonials, too, there was nothing that was held more holy than the marriage by confarreation, and the woman just married used to present a cake made of spelt. Careless cultivation of the land was in those times an offence that came under the cognizance of the censors; and, as we learn from Cato, when it was said that such and such a man was a good agriculturist or a good husbandman, it was looked upon as the very highest compliment that could be paid him. A man came to be called “locuples,” or “rich,” from being “loci plenus,” or “full of earth.” Money, too, received its name of “pecunia,” from “pecus,” “cattle.” At the present day, even, in the registers of the censors, we find set down under the head of “pascua,” or “pasture lands,” everything from which the public revenues are derived, from the fact that for a long period of time pasture lands were the only sources of the public revenue. Fines, too, were only imposed in the shape of paying so many sheep or so many oxen; and the benevolent spirit of the ancient laws deserves remark, which most considerably enjoined that the magistrate, when he inflicted a penalty, should never impose a fine of an ox before having first condemned the same party to the payment of a sheep.

Those who celebrated the public games in honour of the ox received the name of Bubetii. King Servius was the first who impressed upon our copper coin the figures of sheep and oxen. To depasture cattle secretly by night upon the unripe crops on plough lands, or to cut them in that state, was made by the Twelve Tables a capital offence in the case of an adult; and it was enacted that the person guilty of it should be hanged, in order to make due reparation to the

goddess Ceres, a punishment more severe, even, than that inflicted for murder. If, on the other hand, the offender was not an adult, he was beaten at the discretion of the prætor; a penalty double the amount of the damage was also exacted.

The various ranks, too, and distinctions in the state had no other origin than the pursuits of agriculture. The rural tribes held the foremost rank, and were composed of those who possessed lands; while those of the city, a place to which it was looked upon as ignominious to be transferred, had the discredit thrown upon them of being an indolent race. Hence it was that these last were only four in number, and received their names from the several parts of the City which they respectively inhabited; being the Suburran, the Palatine, Colline, and Exquiline tribes. Every ninth day the rural tribes used to visit the city for the purpose of marketing, and it was for this reason that it was made illegal to hold the comitia upon the Nundinæ; the object being that the country people might not be called away thereby from the transaction of their business. In those days repose and sleep were enjoyed upon straw. Even to glory itself, in compliment to corn, the name was given of “adorea.”

For my own part, I greatly admire the modes of expression employed in our ancient language: thus, for instance, we read in the Commentaries of the Priesthood to the following effect:— “For deriving an augury from the sacrifice of a bitch, a day should be set apart before the ear of corn appears from out of the sheath, and then again before it enters the sheath.”

Detailed table of contents

CHAP. 4.

HOW OFTEN AND ON WHAT OCCASIONS CORN HAS SOLD AT A REMARKABLY LOW PRICE.

The consequence was, that when the Roman manners were such as these, the corn that Italy produced was sufficient for its wants, and it had to be indebted to no province for its food; and not only this, but the price of provisions was incredibly cheap. Manius Marcius, the ædile of the people, was the first who gave corn to the people at the price of one as for the modius. L. Minutius Augurinus, the same who detected, when eleventh tribune of the people, the projects of Spurius Mælius, reduced the price of corn on three market days, to one as per modius; for which reason a statue was erected in honour of him, by public subscription, without the Trigeminian Gate. T. Seius distributed corn to the people, in his ædileship, at one as per modius, in remembrance of which statues were erected in honour of him also in the Capitol and the Palatium: on the day of his funeral he was borne to the pile on the shoulders of the Roman people. In the year, too, in which the Mother of the Gods was brought to Rome, the harvest of that summer, it is said, was more abundant than it had been for ten years before. M. Yarro informs us, that in the year in which L. Metellus exhibited so many elephants in his triumphal procession, a modius of spelt was sold for one as, which was the standard price also of a congius of wine, thirty pounds' weight of dried figs, ten pounds of olive oil, and twelve pounds of flesh meat. Nor did this cheapness originate in the wide-spread domains of individuals encroaching continually upon their neighbours, for by a law proposed by Licinius Stolo, the landed property of each individual was limited to five hundred jugera; and he himself was convicted under his own law of being the owner of more than that amount, having as a disguise prevailed upon his son to lend him his name. Such were the prices of commodities at a time when the fortunes of the republic were rapidly on the increase. The words, too, that were uttered by Manius Curius after his triumphs and the addition of an immense extent of territory to the Roman sway, are well known: "The man must be looked upon," said he, "as a dangerous citizen, for whom seven jugera of land are not enough;" such being the amount of land that had been allotted to the people after the expulsion of the kings.

What, then, was the cause of a fertility so remarkable as this? The fact, we have every reason to believe, that in those days the lands were tilled by the hands of generals even, the soil exulting beneath a plough-share crowned with wreaths of laurel, and guided by a husbandman graced with triumphs: whether it is that they tended the seed with the same care that they had displayed in the conduct of wars, and manifested the same diligent attention in the management of their fields that they had done in the arrangement of the camp, or whether it is that under the hands of honest men everything prospers all the

better, from being attended to with a scrupulous exactness. The honours awarded to Serranus found him engaged in sowing his fields, a circumstance to which he owes his surname. Cincinnatus was ploughing his four jugera of land upon the Vaticanian Hill — the same that are still known as the “Quintian Meadows,” when the messenger brought him the dictatorship — finding him, the tradition says, stripped to the work, and his very face begrimed with dust. “Put on your clothes,” said he, “that I may deliver to you the mandates of the senate and people of Rome.” In those days these messengers bore the name of “viator,” or “wayfarer,” from the circumstance that their usual employment was to fetch the senators and generals from their fields.

But at the present day these same lands are tilled by slaves whose legs are in chains, by the hands of malefactors and men with a branded face! And yet the Earth is not deaf to our adjurations, when we address her by the name of “parent,” and say that she receives our homage in being tilled by hands such as these; as though, forsooth, we ought not to believe that she is reluctant and indignant at being tended in such a manner as this! Indeed, ought we to feel any surprise were the recompense she gives us when worked by chastised slaves, not the same that she used to bestow upon the labours of warriors?

CHAP. 5.

ILLUSTRIOUS MEN WHO HAVE WRITTEN UPON AGRICULTURE.

Hence it was that to give precepts upon agriculture became one of the principal occupations among men of the highest rank, and that in foreign nations even. For among those who have written on this subject we find the names of kings even, Hiero, for instance, Attalus Philometor, and Archelaüs, as well as of generals, Xenophon, for example, and Mago the Carthaginian. Indeed, to this last writer did the Roman senate award such high honours, that, after the capture of Carthage, when it bestowed the libraries of that city upon the petty kings of Africa, it gave orders, in his case only, that his thirty-two Books should be translated into the Latin language, and this, although M. Cato had already compiled his Book of Precepts; it took every care also to entrust the execution of this task to men who were well versed in the Carthaginian tongue, among whom was pre-eminent D. Silanus, a member of one of the most illustrious families of Rome. I have already indicated, at the commencement of this work, the numerous learned authors and writers in verse, together with other illustrious men, whose authority it is any intention to follow; but among the number I may here more particularly distinguish M. Yarro, who, at the advanced age of eighty-eight years, thought it his duty to publish a treatise upon this subject.

(4.) Among the Romans the cultivation of the vine was introduced at a comparatively recent period, and at first, as indeed they were obliged to do, they paid their sole attention to the culture of the fields. The various methods of cultivating the land will now be our subject; and they shall be treated of by us in no ordinary or superficial manner, but in the same spirit in which we have hitherto written; enquiry shall be made with every care first into the usages of ancient days, and then into the discoveries of more recent times, our attention being devoted alike to the primary causes of these operations, and the reasons upon which they are respectively based. We shall make mention, too, of the various constellations, and of the several indications which, beyond all doubt, they afford to the earth; and the more so, from the fact that those writers who have hitherto treated of them with any degree of exactness, seem to have written their works for the use of any class of men but the agriculturist.

CHAP. 6.

POINTS TO BE OBSERVED IN BUYING LAND.

First of all, then, I shall proceed in a great measure according to the dicta of the oracles of agriculture; for there is no branch of practical life in which we find them more numerous or more unerring. And why should we not view in the light of oracles those precepts which have been tested by the infallibility of time and the truthfulness of experience?

(5.) To make a beginning, then, with Cato— “The agricultural population,” says he, “produces the bravest men, the most valiant soldiers, and a class of citizens the least given of all to evil designs. — Do not be too eager in buying a farm. — In rural operations never be sparing of your trouble, and, above all, when you are purchasing land. — A bad bargain is always a ground for repentance. — Those who are about to purchase land, should always have an eye more particularly to the water there, the roads, and the neighbourhood.” Each of these points is susceptible of a very extended explanation, and replete with undoubted truths. Cato recommends, too, that an eye should be given to the people in the neighbourhood, to see how they look: “For where the land is good,” says he, “the people will look well-conditioned and healthy.”

Atilius Regulus, the same who was twice consul in the Punic War, used to say that a person should neither buy an unhealthy piece of land in the most fertile locality, nor yet the very healthiest spot if in a barren country. The salubrity of land, however, is not always to be judged of from the looks of the inhabitants, for those who are well-seasoned are able to withstand the effects of living in pestilent localities even. And then, besides, there are some localities that are healthy during certain periods of the year only; though, in reality, there is no soil that can be looked upon as really valuable that is not healthy all the year through. “That is sure to be bad land against which its owner has a continual struggle.” Cato recommends us before everything, to see that the land which we are about to purchase not only excels in the advantages of locality, as already stated, but is really good of itself. We should see, too, he says, that there is an abundance of manual labour in the neighbourhood, as well as a thriving town; that there are either rivers or roads, to facilitate the carriage of the produce; that the buildings upon the land are substantially erected, and that the land itself bears every mark of having been carefully tilled — a point upon which I find that many persons are greatly mistaken, as they are apt to imagine that the negligence of the previous owner is greatly to the purchaser’s advantage; while the fact is, that there is nothing more expensive than the cultivation of a neglected soil.

For this reason it is that Cato says that it is best to buy land of a careful proprietor, and that the methods adopted by others ought not to be hastily

rejected — that it is the same with land as with mankind — however great the proceeds, if at the same time it is lavish and extravagant, there will be no great profits left. Cato looks upon a vineyard as the most profitable investment; and he is far from wrong in that opinion, seeing that he takes such particular care to retrench all superfluous expenses. In the second rank he places gardens that have a good supply of water, and with good reason, too, supposing always that they are near a town. The ancients gave to meadow lands the name of “parata,” or lands “always ready.”

Cato being asked, on one occasion, what was the most certain source of profit, “Good pasture land,” was his answer; upon which, enquiry was made what was the next best. “Pretty good pasture lands,” said he — the amount of all which is, that he looked upon that as the most certain source of income which stands in need of the smallest outlay. This, however, will naturally vary in degree, according to the nature of the respective localities; and the same is the case with the maxim to which he gives utterance, that a good agriculturist must be fond of selling. The same, too, with his remark, that in his youth a landowner should begin to plant without delay, but that he ought not to build until the land is fully brought into cultivation, and then only a little at a time: and that the best plan is, as the common proverb has it, “To profit by the folly of others;” taking due care, however, that the keeping up of a farm-house does not entail too much expense. Still, however, those persons are guilty of no falsehood who are in the habit of saying that a proprietor who is well housed comes all the oftener to his fields, and that “the master’s forehead is of more use than his back.”

[Detailed table of contents](#)

CHAP. 7. (6.)

THE PROPER ARRANGEMENTS FOR A FARM-HOUSE.

The proper plan to be pursued is this: the farm-house must not be unsuitable for the farm, nor the farm for the house; and we must be on our guard against following the examples of L. Lucullus and Q. Scævola, who, though living in the same age, fell into the two opposite extremes; for whereas the farm-house of Scævola was not large enough for the produce of his farm, the farm of Lucullus was not sufficiently large for the house he built upon it; an error which gave occasion to the reproof of the censors, that on his farm there was less of ground for ploughing than of floor for sweeping. The proper arrangements for a farm-house are not to be made without a certain degree of skill. C. Marius, who was seven times consul, was the last person who had one built at Misenum; but he erected it with such a degree of that artistic skill which he had displayed in castrametation, that Sylla Felix even made the remark, that in comparison with Marius, all the others had been no better than blind.

It is generally agreed, that a farm-house ought neither to be built near a marsh, nor with a river in front of it; for, as Homer has remarked, with the greatest correctness, unwholesome vapours are always exhaled from rivers before the rising of the sun. In hot localities, a farm-house should have a northern aspect, but where it is cold, it should look towards the south; where, on the other hand, the site is temperate, the house should look due east. Although, when speaking of the best kinds of soil, I may seem to have sufficiently discussed the characteristics by which it may be known, I shall take the present opportunity of adding a few more indications, employing the words of Cato more particularly for the purpose. "The dwarf-elder," says he, "the wild plum, the bramble, the small bulb, trefoil, meadow grass, the quercus, and the wild pear and wild apple, are all of them indicative of a corn land. The same is the case, too, where the land is black, or of an ashy colour. All chalky soils are scorching, unless they are very thin; the same, too, with sand, unless it is remarkably fine. These remarks, however, are more applicable to champaign localities than declivities."

The ancients were of opinion, that before everything, moderation should be observed in the extent of a farm; for it was a favourite maxim of theirs, that we ought to sow the less, and plough the more: such too, I find, was the opinion entertained by Virgil, and indeed, if we must confess the truth, it is the wide-spread domains that have been the ruin of Italy, and soon will be that of the provinces as well. Six proprietors were in possession of one half of Africa, at the period when the Emperor Nero had them put to death. With that greatness of mind which was so peculiarly his own, and of which he ought not to lose the credit, Cneius Pompeius would never purchase the lands that belonged to a neighbour. Mago has stated it as his opinion, that a person, on

buying a farm, ought at once to sell his town house; an opinion, however, which savours of too great rigidity, and is by no means conformable to the public good. It is with these words, indeed, that he begins his precepts; a good proof, at all events, that he looks upon the personal inspection of the owner as of primary importance.

The next point which requires our care is to employ a farmsteward of experience, and upon this, too, Cato has given many useful precepts. Still, however, it must suffice for me to say that the steward ought to be a man nearly as clever as his master, though without appearing to know it. It is the very worst plan of all, to have land tilled by slaves let loose from the houses of correction, as, indeed, is the case with all work entrusted to men who live without hope. I may possibly appear guilty of some degree of rashness in making mention of a maxim of the ancients, which will very probably be looked upon as quite incredible— “That nothing is so disadvantageous as to cultivate land in the highest style of perfection.” L. Tarius Rufus, a man who, born in the very lowest ranks of life, by his military talents finally attained the consulship, and who in other respects adhered to the old-fashioned notions of thriftiness, made away with about one hundred millions of sesterces, which, by the liberality of the late Emperor Augustus, he had contrived to amass, in buying up lands in Picenum, and cultivating them in the highest style, his object being to gain a name thereby; the consequence of which was, that his heir renounced the inheritance. Are we of opinion, then, that ruin and starvation must be the necessary consequence of such a course as this? Yes, by Hercules! and the very best plan of all is to let moderation guide our judgment in all things. To cultivate land well is absolutely necessary, but to cultivate it in the very highest style is mere extravagance, unless, indeed, the work is done by the hands of a man’s own family, his tenants, or those whom he is obliged to keep at any rate. But besides this, even when the owner tills the land itself, there are some crops which it is really not worth the while to gather, if we only take into account the manual labour expended upon them. The olive, too, should never be too highly cultivated, nor must certain soils, it is said, be too carefully tilled, those of Sicily, for instance; hence it is, that new comers there so often find themselves deceived.

CHAP. 8.

MAXIMS OF THE ANCIENTS ON AGRICULTURE.

In what way, then, can land be most profitably cultivated? Why, in the words of our agricultural oracles, “by making good out of bad.” But here it is only right that we should say a word in justification of our forefathers, who in their precepts on this subject had nothing else in view but the benefit of mankind: for when they use the term “bad” here, they only mean to say that which costs the smallest amount of money. The principal object with them was in all cases to cut down expenses to the lowest possible sum; and it was in this spirit that they made the enactments which pronounced it criminal for a person who had enjoyed a triumph, to be in possession, among his other furniture, of ten pounds’ weight of silver plate: which permitted a man, upon the death of his farmsteward, to abandon all his victories, and return to the cultivation of his lands — such being the men the culture of whose farms the state used to take upon itself; and thus, while they led our armies, did the senate act as their steward.

It was in the same spirit, too, that those oracles of ours have given utterance to these other precepts, to the effect that he is a bad agriculturist who has to buy what his farm might have supplied him with; that the man is a bad manager who does in the day-time what he might have done in the night, except, indeed, when the state of the weather does not allow it; that he is a worse manager still, who does on a work-day what he might have done on a feast-day; but that he is the very worst of all, who works under cover in fine weather, in- stead of labouring in the fields.

I cannot refrain from taking the present opportunity of quoting one illustration afforded us by ancient times, from which it will be found that it was the usage in those days to bring before the people even questions connected with the various methods employed in agriculture, and will be seen in what way men were accustomed to speak out in their own defence. C. Furius Chresimus, a freedman, having found himself able, from a very small piece of land, to raise far more abundant harvests than his neighbours could from the largest farms, became the object of very considerable jealousy among them, and was accordingly accused of enticing away the crops of others by the practice of sorcery. Upon this, a day was named by Spurius Calvinus, the curule ædile, for his appearance. Apprehensive of being condemned, when the question came to be put to the vote among the tribes, he had all his implements of husbandry brought into the Forum, together with his farm servants, robust, Well-conditioned, and well-clad people, Piso says. The iron tools were of first-rate quality, the mattocks were stout and strong, the plough-shares ponderous and substantial, and the oxen sleek and in prime condition. When all this had been done, “Here, Roman citizens,” said he, “are

my implements of magic; but it is impossible for me to exhibit to your view, or to bring into this Forum, those midnight toils of mine, those early watchings those sweats, and those fatigues." Upon this, by the unanimous voice of the people, he was immediately acquitted. Agriculture, in fact, depends upon the expenditure of labour and exertion; and hence it is that the ancients were in the habit of saying, that it is the eye of the master that does more towards fertilizing a field than anything else.

We shall give the rest of these precepts in their appropriate places, according as we find them adapted to each variety of cultivation; but in the meantime we must not omit some of a general nature, which here recur to our recollection, and more particularly that maxim of Cato, as profitable as it is humane: "Always act in such away as to secure the love of your neighbours." He then proceeds to state his reasons for giving this advice, but it appears to me that no one surley can entertain the slightest doubt upon the subject. One of the very first recommendations that he gives is to take every care that the farm servants are kept in good condition. It is a maxim universally agreed upon in agriculture, that nothing must be done too late; and again, that everything must be done at its proper season; while there is a third precept, which reminds us that opportunities lost can never be regained. The malediction uttered by Cato against rotten ground has been treated of at some length already; but there is another precept which he is never tired of repeating, "Whatever can be done by the help of the ass, will cost the least money."

Fern will be sure to die at the end of a couple of years, if you prevent it from putting forth leaves; the most efficient method of ensuring this is to beat the branches with a stick while they are in bud; for then the juices that drop from it will kill the roots. It is said, too, that fern will not spring up again if it is pulled up by the roots about the turn of the summer solstice, or if the stalks are cut with the edge of a reed, or if it is turned up with a plough-share with a reed placed upon it. In the same way, too, we are told that reeds may be effectually ploughed up, if care is taken to place a stalk of fern upon the share. A field infested with rushes should be turned up with the spade, or, if the locality is stony, with a two-pronged mattock: overgrown shrubs are best removed by fire. Where ground is too moist, it is an advantageous plan to cut trenches in it and so drain it; where the soil is cretaceous, these trenches should be left open; and where it is loose, they should be strengthened with a hedge to prevent them from falling in. When these drains are made on a declivity, they should have a layer of gutter tiles at the bottom, or else house tiles with the face upwards: in some cases, too, they should be covered with earth, and made to run into others of a larger size and wider; the bottom, also, should, if possible, have a coating of stones or of gravel. The openings, too, should be strengthened with two stones placed on either side, and another laid upon the top. Democritus has described a method of rooting up a forest, by first macerating the flower of the lupine for one day in the juice of hemlock,

and then watering the roots of the trees with it.

CHAP. 9. (7.)

THE DIFFERENT KINDS OF GRAIN.

As the field is now prepared, we shall proceed to speak of the nature of the various kinds of grain; we must premise, however, that there are two principal classes of grain, the cereals, comprising wheat and barley, and the legumina, such as the bean and the chick-pea, for instance. The difference between these two classes is too well known to require any further description.

Detailed table of contents

CHAP. 10.

THE HISTORY OF the VARIOUS KINDS OF GRAIN.

The cereals are divided again into the same number of varieties, according to the time of the year at which they are sown. The winter grains are those which are put in the ground about the setting of the Vergiliæ, and there receive their nutriment throughout the winter, for instance, wheat, spelt, and barley. The summer grains are those which are sown in summer, before the rising of the Vergiliæ, such as millet, panic, sesame, horminum, and irio, in accordance, however, with the usage of Italy only; for in Greece and Asia all the grains are sown just after the setting of the Vergiliæ. There are some, again, that are sown at either season in Italy, and others at a third period, or, in other words, in the spring. Some authors give the name of spring-grain to millet, panic, lentils, chick-peas, and alica, while they call wheat, barely, beans, turnips, and rape, sementive or early sowing seeds. Certain species of wheat are only sown to make fodder for cattle, and are known by the name of "farrago," or mixed grain; the same, too, with the leguminous plants, the vetch, for instance. The lupine, however, is grown in common as food for both cattle and men.

All the leguminous plants, with the exception of the bean, have a single root, hard and tough, like wood, and destitute of numerous ramifications; the chick-pea has the deepest root of all. Corn has numerous fibrous roots, but no ramifications. Barley makes its appearance above ground the seventh day after sowing; the leguminous plants on the fourth, or at the very latest, the seventh; the bean from the fifteenth day to the twentieth: though in Egypt the leguminous plants appear as early as the third day after they are sown. In barley, one extremity of the grain throws out the root, and the other the blade; this last flowers, too, before the other grain. In the cereals in general it is the thicker end of the seed that throws out the root, the thinner end the blossom; while in the other seeds both root and blossom issue from the same part.

During the winter, corn is in the blade; but in the spring winter corn throws out a tall stem. As for millet and panic, they grow with a jointed and grooved stalk, while sesame has a stem resembling that of fennel-giant. The fruit of all these seeds is either contained in an ear, as in wheat and barley, for instance, and protected from the attacks of birds and small animals by a prickly beard bristling like so many plisades; or else it is enclosed in pods, as in the leguminous plants, or in capsules, as in sesame and the poppy. Millet and panic can only be said to belong to the grower and the small birds in common, as they have nothing but a thin membrane to cover them, without the slightest protection. Panic receives that name from the panicle or down that is to be seen upon it; the head of it droops languidly, and the stalk tapers gradually in thickness, being of almost the toughness and consistency of wood: the head is loaded with grain closely packed, there being a tuft upon the top, nearly a foot

in length. In millet the husks which embrace the grain bend downward with a wavy tuft upon the edge. There are several varieties of panic, the mammose, for instance, the ears of which are in clusters with small edgings of down, the head of the plant being double; it is distinguished also according to the colour, the white, for instance, the black, the red, and the purple even. Several kinds of bread are made from millet, but very little from panic: there is no grain known that weighs heavier than millet, and which swells more in baking. A modius of millet will yield sixty pounds' weight of bread; and three sextarii steeped in water will make one modius of fermenty. A kind of millet has been introduced from India into Italy within the last ten years, of a swarthy colour, large grain, and a stalk like that of the reed. This stalk springs up to the height of seven feet, and has tufts of a remarkable size, known by the name of "phobæ." This is the most prolific of all the cereals, for from a single grain no less than three sextarii are produced: it requires, however, to be sown in a humid soil.

Some kinds of corn begin to form the ear at the third joint, and others at the fourth, though at its first formation the ear remains still concealed. Wheat, however, has four articulations, spelt six, and barley eight. In the case of these last, the ear does not begin to form before the number of joints, as above mentioned, is complete. Within four or five days, at the very latest, after the ear has given signs of forming, the plant begins to flower, and in the course of as many days or a little more, sheds its blossom: barley blossoms at the end of seven days at the very latest. Varro says that the grains are perfectly formed at the end of four times nine days from their flowering, and are ready for cutting at the ninth month.

The bean, again, first appears in leaf, and then throws out a stalk, which has no articulations upon it. The other leguminous plants have a tough, ligneous stalk, and some of them throw out branches, the chick-pea, the fitch, and the lentil, for instance. In some of the leguminous plants, the pea, for example, the stem creeps along the ground, if care is not taken to support it by sticks: if this precaution is omitted, the quality is deteriorated. The bean and the lupine are the only ones among the leguminous plants that have a single stem: in all the others the stem throws out branches, being of a ligneous nature, very thin, and in all cases hollow. Some of these plants throw out the leaves from the root, others at the top. Wheat, barley, and the vetch, all the plants, in fact, which produce straw, have a single leaf only at the summit: in barley, however, this leaf is rough, while in the others it is smooth. * * * In the bean, again, the chick-pea, and the pea, the leaves are numerous and divided. In corn the leaf is similar to that of the reed, while in the bean it is round, as also in a great proportion of the leguminous plants. In the ervilia and the pea the leaf is long, in the kidney-bean veined, and in sesame and irio the colour of blood. The lupine and the poppy are the only ones among these plants that lose their leaves.

The leguminous plants remain a longer time in flower, the fitch and the chick-pea more particularly; but the bean is in blossom the longest of them all, for the flower remains on it forty days; not, indeed, that each stalk retains its blossom for all that length of time, but, as the flower goes off in one, it comes on in another. In the bean, too, the crop is not ripe all at once, as is the case with corn; for the pods make their appearance at different times, at the lowest parts first, the blossom mounting upwards by degrees.

When the blossom is off in corn, the stalk gradually thickens, and it ripens within forty days at the most. The same is the case, too, with the bean, but the chick-pea takes a much shorter time to ripen; indeed, it is fit for gathering within forty days from the time that it is sown. Millet, panic, sesame, and all the summer grains are ripe within forty days after blossoming with considerable variations, of course, in reference to soil and weather. Thus, in Egypt, we find barley cut at the end of six months, and wheat at the end of seven, from the time of sowing. In Hellas, again, barley is cut in the seventh month, and in Peloponnesus in the eighth; the wheat being got in at a still later period.

Those grains which grow on a stalk of straw are enclosed in an envelope protected by a prickly beard; while in the bean and the leguminous plants in general they are enclosed in pods upon branches which shoot alternately from either side. The cereals are the best able to withstand the winter, but the leguminous plants afford the most substantial food. In wheat, the grain has several coats, but in barley, more particularly, it is naked and exposed; the same, too, with arinca, but most of all, the oat. The stem is taller in wheat than it is in barley, but the ear is more bearded in the last. Wheat, barley, and winter-wheat are threshed out; they are cleaned, too, for sowing just as they are prepared for the mill, there being no necessity for parching them. Spelt, on the other hand, millet, and panic, cannot be cleaned without parching them; hence it is that they are always sown raw and with the chaff on. Spelt is preserved in the husk, too, for sowing, and, of course, is not in such case parched by the action of fire.

[Detailed table of contents](#)

CHAP. 11.

SPELT.

Of all these grains barley is the lightest, its weight rarely exceeding fifteen pounds to the modius, while that of the bean is twenty-two. Spelt is much heavier than barley, and wheat heavier than spelt. In Egypt they make a meal of olyra, a third variety of corn that grows there. The Gauls have also a kind of spelt peculiar to that country: they give it the name of “brace,” while to us it is known as “sanldala:” it has a grain of remarkable whiteness. Another difference, again, is the fact that it yields nearly four pounds more of bread to the modius than any other kind of spelt. Verrius states that for three hundred years the Romans made use of no other meal than that of corn.

[Detailed table of contents](#)

CHAP. 12.

WHEAT.

There are numerous kinds of wheat which have received their names from the countries where they were first produced. For my part, however, I can compare no kind of wheat to that of Italy either for whiteness or weight, qualities for which it is more particularly distinguished: indeed it is only with the produce of the more mountainous parts of Italy that the foreign wheats can be put in comparison. Among these the wheat of Bœotia occupies the first rank, that of Sicily the second, and that of Africa the third. The wheats of Thrace, Syria, and, more recently, of Egypt, used to hold the third rank for weight, these facts having been ascertained through the medium of the athletes; whose powers of consumption, equal to those of beasts of burden, have established the gradations in weight, as already stated. Greece, too, held the Pontic wheat in high esteem; but this has not reached Italy as yet. Of all the varieties of grain, however, the Greeks gave the preference to the kinds called dracontion, strangia, and Selinusium, the chief characteristic of which is a stem of remarkable thickness: it was this, in the opinion of the Greeks, that marked them as the peculiar growth of a rich soil. On the other hand, they recommended for sowing in humid soils an extremely light and diminutive species of grain, with a remarkably thin stalk, known to them as speudias, and standing in need of an abundance of nutriment. Such, at all events, were the opinions generally entertained in the reign of Alexander the Great, at a time when Greece was at the height of her glory, and the most powerful country in the world. Still, however, nearly one hundred and forty-four years before the death of that prince we find the poet Sophocles, in his Tragedy of “Triptolemus,” praising the corn of Italy before all others. The passage, translated word for word, is to the following effect:— “And favour’d Italy grows white with hoary wheat.”

And it is this whiteness that is still one of the peculiar merits of the Italian wheat; a circumstance which makes me the more surprised to find that none of the Greek writers of a later period have made any reference to it.

Of the various kinds of wheat which are imported at the present day into Rome, the lightest in weight are those which come from Gaul and Chersonnesus; for, upon weighing them, it will be found that they do not yield more than twenty pounds to the modius. The grain of Sardinia weighs half a pound more, and that of Alexandria one-third of a pound more than that of Sardinia; the Sicilian wheat is the same in weight as the Alexandrian. The Bœotian wheat, again, weighs a whole pound more than these last, and that of Africa a pound and three quarters. In Italy beyond the Padus, the spelt, to my knowledge, weighs twenty-five pounds to the modius, and, in the vicinity of Clusium, six-and-twenty. We find it a rule, universally established by Nature,

that in every kind of commissariat bread that is made, the bread exceeds the weight of the grain by one-third; and in the same way it is generally considered that that is the best kind of wheat, which, in kneading, will absorb one congius of water. There are some kinds of wheat which give, when used by themselves, an additional weight equal to this; the Balearic wheat, for instance, which to a modius of grain yields thirty-five pounds weight of bread. Others, again, will only give this additional weight by being mixed with other kinds, the Cyprian wheat and the Alexandrian, for example; which, if used by themselves, will yield no more than twenty pounds to the modius. The wheat of Cyprus is swarthy, and produces a dark bread; for which reason it is generally mixed with the white wheat of Alexandria; the mixture yielding twenty-five pounds of bread to the modius of grain. The wheat of Thebais, in Egypt, æhen made into bread, yields twenty-six pounds to the modius. To knead the meal with sea-water, as is mostly done in the maritime districts, for the purpose of saving the salt, is extremely pernicious; there is nothing, in fact, that will more readily predispose the human body to disease. In Gaul and Spain, where they make a drink by steeping corn in the way that has been already described — they employ the foam which thickens upon the surface as a leaven: hence it is that the bread in those countries is lighter than that made else- where.

There are some differences, also, in the stem of wheat; for the better the kind the thicker it is. In Thrace, the stem of the wheat is covered with several coats, which are rendered absolutely necessary by the excessive cold of those regions. It is the cold, also, that led to the discovery there of the three-month wheat, the ground being covered with snow most of the year. At the end mostly of three months after it has been sown, this wheat is ready for cutting, both in Thrace and in other parts of the world as well. This variety is well known, too, throughout all the Alpine range, and in the northern provinces there is no kind of wheat that is more prolific; it has a single stem only, is by no means of large size in any part of it, and is never sown but in a thin, light soil. There is a two-month wheat also found in the vicinity of Ænos, in Thrace, which ripens the fortieth day after sowing; and yet it is a surprising fact, that there is no kind of wheat that weighs heavier than this, while at the same time it produces no bran. Both Sicily and Achaia grow it, in the mountainous districts of those countries; as also Eubœa, in the vicinity of Carystus. So greatly, then, is Columella in error, in supposing that there is no distinct variety of three-month wheat even; the fact being that these varieties have been known from the very earliest times. The Greeks give to these wheats the name of “setanion.” It is said that in Bactria the grains of wheat are of such an enormous size, that a single one is as large as our ears of corn.

CHAP. 13.

BARLEY: RICE.

Of all the cereals the first that is sown is barley. We shall state the appropriate time for sowing each kind when we come to treat of the nature of each individually. In India, there is both a cultivated and a wild barley, from which they make excellent bread, as well as alica. But the most favourite food of all there is rice, from which they prepare a ptisan similar to that made from barley in other parts of the world. The leaves of rice are fleshy, very like those of the leek, but broader; the stem is a cubit in height, the blossom purple, and the root globular, like a pearl in shape.

CHAP. 14.

POLENTA.

Barley is one of the most ancient aliments of man, a fact that is proved by a custom of the Athenians, mentioned by Menander, as also by the name of “hordearii,” that used to be given to gladiators. The Greeks, too, prefer barley to anything else for making polenta. This food is made in various ways: in Greece, the barley is first steeped in water, and then left a night to dry. The next day they parch it, and then grind it in the mill. Some persons parch it more highly, and then sprinkle it again with a little water; after which they dry it for grinding. Others shake the grain from out of the ear while green, and, after cleaning and soaking it in water, pound it in a mortar. They then wash the paste in baskets, and leave it to dry in the sun; after which they pound it again, clean it, and grind it in the mill. But whatever the mode of preparation adopted, the proportions are always twenty pounds of barley to three pounds of linseed, half a pound of coriander, and fifteen drachmæ of salt: the ingredients are first parched, and then ground in the mill.

Those who want it for keeping, store it in new earthen vessels, with fine flour and bran. In Italy, the barley is parched without being steeped in water, and then ground to a fine meal, with the addition of the ingredients already mentioned, and some millet as well. Barley bread, which was extensively used by the ancients, has now fallen into universal disrepute, and is mostly used as a food for cattle only.

Detailed table of contents

CHAP. 15.

PTISAN.

With barley, too, the food called ptisan is made, a most substantial and salutary aliment, and one that is held in very high esteem. Hippocrates, one of the most famous writers on medical science, has devoted a whole volume to the praises of this aliment. The ptisan of the highest quality is that which is made at Utica; that of Egypt is prepared from a kind of barley, the grain of which grows with two points. In Baltic and Africa, the kind of barley from which this food is made is that which Turranius calls the “smooth” barley: the same author expresses an opinion, too, that olyra and rice are the same. The method of preparing ptisan is universally known.

Detailed table of contents

CHAP. 16.

TRAGUM.

In a similar manner, too, tragum is prepared from seed wheat, but only in Campania and Egypt.

[Detailed table of contents](#)

CHAP. 17.

AMYLUM.

Amylum is prepared from every kind of wheat, and from winter-wheat as well; but the best of all is that made from three-month wheat. The invention of it we owe to the island of Chios, and still, at the present day, the most esteemed kind comes from there; it derives its name from its being made without the help of the mill. Next to the amyllum made with three-month wheat, is that which is prepared from the lighter kinds of wheat. In making it, the grain is soaked in fresh water, placed in wooden vessels; care being taken to keep it covered with the liquid, which is changed no less than five times in the course of the day. If it can be changed at night as well, it is all the better for it, the object being to let it imbibe the water gradually and equally. When it is quitæ soft, but before it turns sour, it is passed through linen cloth, or else wicker-work, after which it is poured out upon a tile covered with leaven, and left to harden in the sun. Next to the amyllum of Chios, that of Crete is the most esteemed, and next to that the Ægyptian. The tests of its goodness are its being light and smooth: it should be used, too, while it is fresh. Cato, among our writers, has made mention of it.

[Detailed table of contents](#)

CHAP. 18.

the NATURE OF BARLEY.

Barley-meal, too, is employed for medicinal purposes; and it is a curious fact, that for beasts of burden they make a paste of it, which is first hardened by the action of fire, and then ground. It is then made up into balls, which are introduced with the hand into the paunch, the result of which is, that the vigour and muscular strength of the animal is considerably increased. In some kinds of barley, the ears have two rows of grains, and in others more; in some cases, as many as six. The grain itself, too, presents certain differences, being long and thin, or else short or round, white, black, or, in some instances, of a purple colour. This last kind is employed for making polenta: the white is ill adapted for standing the severity of the weather. Barley is the softest of all the grains: it can only be sown in a dry, loose soil, but fertile withal. The chaff of barley ranks among the very best; indeed, for litter there is none that can be compared with it. Of all grain, barley is the least exposed to accidents, as it is gathered before the time that mildew begins to attack wheat; for which reason it is that the provident agriculturist sows only as much wheat as may be required for food. The saying is, that “barley is sown in a money-bag,” because it so soon returns a profit. The most prolific kind of all is that which is got in at Carthage, in Spain, in the month of April. It is in the same month that it is sown in Celtiberia, and yet it yields two harvests in the same year. All kinds of barley are cut sooner than other grain, and immediately after they are ripe; for the straw is extremely brittle, and the grain is enclosed in a husk of remarkable thinness. It is said, too, that a better polenta is made from it, if it is gathered before it is perfectly ripe.

Detailed table of contents

CHAP. 19. (8.)

ARINCA, AND OTHER KINDS OF GRAIN THAT ARE GROWN IN THE EAST.

The several kinds of corn are not everywhere the same; and even where they are the same, they do not always bear a similar name. The kinds most universally grown are spelt, by the ancients known as “adorea,” winter wheat, and wheat; all these being common to many countries. Arinca was originally peculiar to Gaul, though now it is widely diffused over Italy as well. Egypt, too, Syria, Cilicia, Asia, and Greece, have their own peculiar kinds, known by the names of zea, olyra, and wheat. In Egypt, they make a fine flour from wheat of their own growth, but it is by no means equal to that of Italy. Those countries which employ zea, have no spelt. Zea, however, is to be found in Italy, and in Campania more particularly, where it is known by the name of “seed.” The grain that bears this name enjoys a very considerable celebrity, as we shall have occasion to state on another occasion; and it is in honour of this that Homer uses the expression, ζειδωρος ἄρουρα, and not, as some suppose, from the fact of the earth giving life. Amylum is made, too, from this grain, but of a coarser quality than the kind already mentioned; this, however, is the only difference that is perceptible.

The most hardy kind, however, of all the grains is spelt, and the best to stand the severity of the weather; it will grow in the very coldest places, as also in localities that are but half tilled, or soils that are extremely hot, and destitute of water. This was the earliest food of the ancient inhabitants of Latium; a strong proof of which is the distributions of adorea that were made in those times, as already stated. It is evident, too, that the Romans subsisted for a long time upon pottage, and not bread; for we find that from its name of “puls,” certain kinds of food are known, even at the present day, as “pulmentaria.” Ennius, too, the most ancient of our poets, in describing the famine in a siege, relates how that the parents snatched away the messes of pottage from their weeping children. At the present day, even, the sacrifices in conformity with the ancient rites, as well as those offered upon birthdays, are made with parched pottage. This food appears to have been as much unknown in those days in Greece as polenta was in Italy.

Detailed table of contents

CHAP. 20.

WINTER WHEAT. SIMILAGO, OR FINE FLOUR.

There is no grain that displays a greater avidity than wheat, and none that absorbs a greater quantity of nutriment. With all propriety I may justly call winter wheat the very choicest of all the varieties of wheat. It is white, destitute of all flavour, and not oppressive to the stomach. It suits moist localities particularly well, such as we find in Italy and Gallia Comata; but beyond the Alps it is found to maintain its character only in the territory of the Allobroges and that of the Memini; for in the other parts of those countries it degenerates at the end of two years into common wheat. The only method of preventing this is to take care and sow the heaviest grains only.

(9.) Winter wheat furnishes bread of the very finest quality and the most esteemed delicacies of the bakers. The best bread that is known in Italy is made from a mixture of Campanian winter wheat with that of Pisæ. The Campanian kind is of a redder colour, while the latter is white; when mixed with chalk, it is increased in weight. The proper proportion for the yield of Campanian wheat to the modius of grain is four sextarii of what is known as bolted flour; but when it is used in the rough and has not been bolted, then the yield should be five sextarii of flour. In addition to this, in either case there should be half a modius of white meal, with four sextarii of coarse meal, known as “seconds,” and the same quantity of bran. The Pisan wheat produces five sextarii of fine flour to the modius; in other respects it yields the same as that of Campania. The wheat of Clusium and Arretium gives another sextarius of fine flour, but the yield is similar to that of the kinds already mentioned in all other respects. If, however, as much of it as possible is converted into fine wheat meal, the modius will yield sixteen pounds weight of white bread, and three of seconds, with half a modius of bran. These differences, however, depend very materially upon the grinding; for when the grain is ground quite dry it produces more meal, but when sprinkled with salt water a whiter flour, though at the same time a greater quantity of bran. It is very evident that “firina,” the name we give to meal, is derived from “far.” A modius of meal made from Gallic winter wheat, yields twenty-two pounds of bread; while that of Italy, if made into bread baked in tins, will yield two or three pounds more. When the bread is baked in the oven, two pounds must be added in weight in either case.

(10.) Wheat yields a fine flour of the very highest quality. In African wheat the modius ought to yield half a modius of fine flour and five sextarii of pollen, that being the name given to fine wheat meal, in the same way that that of winter wheat is generally known as “fos,” or the “flower.” This fine meal is extensively used in copper works and paper manufactories. In addition to the above, the modius should yield four sextarii of coarse meal, and the same

quantity of bran. The finest wheaten flour will yield one hundred and twenty-two pounds of bread, and the fine meal of winter wheat one hundred and seventeen, to the modius of grain. When the prices of grain are moderate, meal sells at forty asses the modius, bolted wheaten flour at eight asses more, and bolted flour of winter wheat, at sixteen asses more. There is another distinction again in fine wheaten flour, which originated formerly in the days of L. Paul's. There were three classes of wheat; the first of which would appear to have yielded seventeen pounds of bread, the second eighteen, and the third nineteen pounds and a third: to these were added two pounds and a half of seconds, and the same quantity of brown bread, with six sextarii of bran.

Winter wheat never ripens all at once, and yet there is none of the cereals that can so ill brook any delay; it being of so delicate a nature, that the ears directly they are ripe will begin to shed their grain. So long, however, as it is in stalk, it is exposed to fewer risks than other kinds of wheat, from the fact of its always having the ear upright, and not retaining the dew, which is a prolific cause of mildew.

From arinca a bread of remarkable sweetness is made. The grains in this variety lie closer than they do in spelt; the ear, too, is larger and more weighty. It is rarely the case that a modius of this grain does not weigh full sixteen pounds. In Greece they find great difficulty in threshing it; and hence it is that we find Homer saying that it is given to beasts of burden, this being the same as the grain that he calls "olyra." In Egypt it is threshed without any difficulty, and is remarkably prolific. Spelt has no beard, and the same is the case with winter wheat, except that known as the Laconion variety. To the kinds already mentioned we have to add bromos, the winter wheat just excepted, and tragos, all of them exotics introduced from the East, and very similar to rice. Tiphe also belongs to the same class, from which in our part of the world a cleaned grain resembling rice is prepared. Among the Greeks, too, there is the grain known as zea; and it is said that this, as well as tiphe, when cleaned from the husk and sown, will degenerate and assume the form of wheat; not immediately, but in the course of three years.

CHAP. 21.

THE FRUITFULNESS OF AFRICA IN WHEAT.

There is no grain more prolific than wheat, Nature having bestowed upon it this quality, as being the substance which she destined for the principal nutriment of man. A modius of wheat, if the soil is favourable, as at Byzacium, a champaign district of Africa, will yield as much as one hundred and fifty modii of grain. The procurator of the late Emperor Augustus sent him from that place — a fact almost beyond belief — little short of four hundred shoots all springing from a single grain; and we have still in existence his letters on the subject. In a similar manner, too, the procurator of Nero sent him three hundred and sixty stalks all issuing from a single grain. The plains of Leontium in Sicily, and other places in that island, as well as the whole of Bætica, and Egypt more particularly, yield produce a hundred-fold. The most prolific kinds of wheat are the ramose wheat, and that known as the “hun- dred-grain” wheat. Before now, as many as one hundred beans, too, have been found on a single stalk.

CHAP. 22.

SESAME. ERYSIMUM, OR IRIO. HORMINUTM.

We have spoken of sesame, millet, and panic as belonging to the summer grains. Sesame comes from India, where they extract an oil from it; the colour of its grain is white. Similar in appearance to this is the erysimum of Asia and Greece, and indeed it would be identical with it were it not that the grain is better filled. It is the same grain that is known among us as “irio;” and strictly speaking, ought rather to be classed among the medicaments than the cereals. Of the same nature, too, is the plant called “horminum” by the Greeks, though resembling cummin in appearance; it is sown at the same time as sesame: no animal will eat either this or irio while green.

Detailed table of contents

CHAP. 23.

THE MODE OF GRINDING CORN.

All the grains aræ not easily broken. In Etruria they first parch the spelt in the ear, and then pound it with a pestle shod with iron at the end. In this instrument the iron is notched at the bottom, sharp ridges running out like the edge of a knife, and concentrating in the form of a star; so that if care is not taken to hold the pestle perpendicularly while pounding, the grains will only be splintered and the iron teeth broken. Throughout the greater part of Italy, however, they employ a pestle that is only rough at the end, and wheels turned by water, by means of which the corn is gradually ground. I shall here set forth the opinions given by Mago as to the best method of pounding corn. He says that the wheat should be steeped first of all in water, and then cleaned from the husk; after which it should be dried in the sun, and then pounded with the pestle; the same plan, he says, should be adopted in the preparation of barley. In the latter case, however, twenty sextarii of grain require only two sextarii of water. When lentils are used, they should be first parched, and then lightly pounded with, the bran; or else, adopting another method, a piece of unbaked brick and half a modius of sand should be added to every twenty sextarii of lentils.

Ervilia should be treated in the same way as lentils. Sesame should be first steeped in warm water, and then laid out to dry, after which it should be rubbed out briskly, and then thrown into cold water, so that the chaff may be disengaged by floating to the surface. After this is done, the grain should again be spread out in the sun, upon linen cloths, to dry. Care, however, should be taken to lose no time in doing this, as it is apt to turn musty, and assume a dull, livid colour. The grains, too, which are just cleaned from the husk, require various methods of pounding. When the beard is ground by itself, without the grain, the result is known as “acus,” but it is only used by goldsmiths. If, on the other hand, it is beaten out on the threshing-floor, together with the straw, the chaff has the name of “palea,” * * * * and in most parts of the world is employed as fodder for beasts of burden. The residue of millet, panic, and sesame, is known to us as “apluda;” but in other countries it is called by various other names.

Detailed table of contents

CHAP. 24.

MILLET.

Campania is particularly prolific in millet, and a fine white porridge is made from it: it makes a bread, too, of remarkable sweetness. The nations of Sarmatia live principally on this porridge, and even the raw meal, with the sole addition of mares' milk, or else blood extracted from the thigh of the horse. The Æthiopians know of no other grain but millet and barley.

[Detailed table of contents](#)

CHAP. 25.

PANIC.

The people of Gaul, and of Aquitania more particularly, make use of panic; the same is the case, too, in Italy beyond the Padus, with the addition, however, of the bean, without which they prepare none of their food. There is no aliment held in higher esteem than panic by the nations of Pontus. The other summer grains thrive better in well-watered soils than in rainy localities; but water is by no means beneficial to millet or panic when they are coming into blade. It is recommended not to sow them among vines or fruit-trees, as it is generally thought that these crops impoverish the soil.

[Detailed table of contents](#)

CHAP. 26. (11)

THE VARIOUS KINDS OF LEAVEN.

Millet is more particularly employed for making leaven; and if kneaded with must, it will keep a whole year. The same is done, too, with the fine wheat-bran of the best quality; it is kneaded with white must three days old, and then dried in the sun, after which it is made into small cakes. When required for making bread, these cakes are first soaked in water, and then boiled with the finest spelt flour, after which the whole is mixed up with the meal; and it is generally thought that this is the best method of making bread. The Greeks have established a rule that for a modius of meal eight ounces of leaven is enough.

These kinds of leaven, however, can only be made at the time of vintage, but there is another leaven which may be prepared with barley and water, at any time it may happen to be required. It is first made up into cakes of two pounds in weight, and these are then baked upon a hot hearth, or else in an earthen dish upon hot ashes and charcoal, being left till they turn of a reddish brown. When this is done, the cakes are shut close in vessels, until they turn quite sour: when wanted for leaven, they are steeped in water first. When barley bread used to be made, it was leavened with the meal of the fitch, or else the chicheling vetch, the proportion being, two pounds of leaven to two modii and a half of barley meal. At the present day, however, the leaven is prepared from the meal that is used for making the bread. For this purpose, some of the meal is kneaded before adding the salt, and is then boiled to the consistency of porridge, and left till it begins to turn sour. In most cases, however, they do not warm it at all, but only make use of a little of the dough that has been kept from the day before. It is very evident that the principle which causes the dough to rise is of an acid nature, and it is equally evident that those persons who are dieted upon fermented bread are stronger in body. Among the ancients, too, it was generally thought that the heavier wheat is, the more wholesome it is.

[Detailed table of contents](#)

CHAP. 27.

THE METHOD OF MAKING BREAD: ORIGIN OF THE ART.

It seems to me quite unnecessary to enter into an account of the various kinds of bread that are made. Some kinds, we find, receive their names from the dishes with which they are eaten, the oyster-bread, for instance: others, again, from their peculiar delicacy, the artolaganus, or cake-bread, for example; and others from the expedition with which they are prepared, such as the “speusticus,” or “hurry-bread.” Other varieties receive their names from the peculiar method of baking them, such as oven-bread, tin-bread, and mould-bread. It is not so very long since that we had a bread introduced from Parthia, known as water-bread, from a method in kneading it, of drawing out the dough by the aid of water, a process which renders it remarkably light, and full of holes, like a sponge: some call this Parthian bread. The excellence of the finest kinds of bread depends principally on the goodness of the wheat, and the fineness of the bolter. Some persons knead the dough with eggs or milk, and butter even has been employed for the purpose by nations that have had leisure to cultivate the arts of peace, and to give their attention to the art of making pastry. Picenum still maintains its ancient reputation for making the bread which it was the first to invent, alica being the grain employed. The flour is kept in soak for nine days, and is kneaded on the tenth with raisin juice, in the shape of long rolls; after which it is baked in an oven in earthen pots, till they break. This bread, however, is never eaten till it has been well soaked, which is mostly done in milk mixed with honey.

Detailed table of contents

CHAP. 28.

WHEN BAKERS WERE FIRST INTRODUCED AT ROME.

There were no bakers at Rome until the war with King Perseus, more than five hundred and eighty years after the building of the City. The ancient Romans used to make their own bread, it being an occupation which belonged to the women, as we see the case in many nations even at the present day. Plautus speaks of the artopta, or bread-tin, in his Comedy of the Alularia, though there has been considerable discussion for that very reason among the learned, whether or not that line really belongs to him. We have the fact, too, well ascertained, in the opinion of Ateius Capito, that the cooks in those days were in the habit of making the bread for persons of affluence, while the name of “pistor” was only given to the person who pounded, or “pisebat,” the spelt. In those times, they had no cooks in the number of their slaves but used to hire them for the occasion from the market. The Gauls were the first to employ the bolter that is made of horse-hair; while the people of Spain make their sieves and meal-dressers of flax, and the Egyptians of papyrus and rushes.

Detailed table of contents

CHAP. 29.

ALTCA.

But among the very first things of all, we ought to speak of the method employed in preparing alica, a most delightful and most wholesome food, and which incontestably confers upon Italy the highest rank among the countries that produce the cereals. This delicacy is prepared, no doubt, in Egypt as well, but of a very inferior quality, and not worth our notice. In Italy, however, it is prepared in numerous places, the territories of Verona and Pisæ, for example; but that of Campania is the most highly esteemed. There, at the foot of mountains capped with clouds, runs a plain, not less in all than forty miles in extent. The land here — to give a description first of the nature of the soil — is dusty on the surface, but spongy below, and as porous as pumice. The inconveniences that generally arise from the close vicinity of mountains are here converted into so many advantages: for the soil, acting on it as a sort of filter, absorbs the water of the abundant rains that fall; the consequence of which is, that the water not being left to soak or form mud on the surface, the cultivation is greatly facilitated thereby. This land does not return, by the aid of any springs, the moisture it has thus absorbed, but thoroughly digests it, by warming it in its bosom, in a heated oven as it were. The ground is kept cropped the whole year through, once with panic, and twice with spelt; and yet in the spring, when the soil is allowed to have a moment's repose, it will produce roses more odoriferous by far than the cultivated rose: for the earth here is never tired of producing, a circumstance in which originated the common saying, that Campania produces more unguents than other countries do oil.

In the same degree, however, that the Campanian soil excels that of all other countries, so does that part of it which is known to us as Laboriæ, and to the Greeks as Phlegræum, surpass all the rest. This district is bounded on two sides by the consular high road, which leads from Puteoli to Capua on the one side, and from Cumæ on the other.

Alica is prepared from the grain called *zea*, which we have already mentioned as being known to us as “seed” wheat. The grain is cleansed in a wooden mortar, for fear lest stone, from its hardness, should have the effect of grating it. The motive power for raising the pestle, as is generally known, is supplied by slaves working in chains, the end of it being enclosed in a case of iron. After the husks have been removed by this process, the pure grain is broken to pieces, the same implements being employed. In this way, there are three different kinds of alica made, the finest, the seconds, and the coarse, which last is known as “aphærema.” Still, however, these various kinds have none of them that whiteness as yet for which they are so distinguished, though even now they are preferable to the Alexandrian alica. With this view — a

most singular fact — chalk is mixed with the meal, which, upon becoming well incorporated with it, adds very materially to both the whiteness and the shortness of the mixture. This chalk is found between Puteoli and Neapolis, upon a hill called Leucogæum; and there is still in existence a decree of the late Emperor Augustus, (who established a colony at Capua), which orders a sum of twenty thousand sesterces to be paid annually from his exchequer to the people of Neapolis, for the lease of this hill. His motive for paying this rent, he stated, was the fact that the people of Campania had alleged that it was impossible to make their alica without the help of this mineral. In the same hill, sulphur is found as well, and the springs of Araxus issue from its declivities, the waters of which are particularly efficacious for strengthening the sight, healing wounds, and preventing the teeth from becoming loose.

A spurious kind of alica is made, more particularly of a degenerate kind of zea grown in Africa; the ears of it are larger and blacker than those of the genuine kind, and the straw is short. This grain is pounded with sand, and even then it is with the greatest difficulty that the outer coats are removed; when stripped, the grain fills one half only of the original measure. Gypsum, in the proportion of one fourth, is then sprinkled over it, and after the mixture has been well incorporated, it is bolted through a meal-sieve. The portion that remains behind, after this is done, is known as “excepticia,” and consists of the coarser parts; while that which has passed through is submitted to a second process, with a finer sieve; and that which then refuses to pass has the name of “secundaria.” That, again, which, in a similar manner, is submitted to a third sifting, with a sieve of the greatest fineness, which will only admit of sand passing through it, is known as “cribraria,” when it remains on the top of the sieve.

There is another method, again, that is employed every where for adulterating it. They pick out the whitest and largest grains of wheat, and parboil them in earthen pots; these are then dried in the sun till they have regained their original size, after which they are lightly sprinkled with water, and then ground in a mill. A better granæum is made from zea than from wheat, although it is nothing else, in fact, but a spurious alica: it is whitened by the addition of boiled milk, in place of chalk.

Detailed table of contents

CHAP. 30. (12.)

THE LEGUMINOUS PLANTS: THE BEAN.

We now come to the history of the leguminous plants, among which the place of honour must be awarded to the bean; indeed, some attempts have even been made to use it for bread. Bean meal is known as “lomentum;” and, as is the case with the meal of all leguminous plants, it adds considerably, when mixed with flour, to the weight of the bread. Beans are on sale at the present day for numerous purposes, and are employed for feeding cattle, and man more particularly. They are mixed, also, among most nations, with wheat, and panic more particularly, either whole or lightly broken. In our ancient ceremonials, too, bean pottage occupies its place in the religious services of the gods. Beans are mostly eaten together with other food, but it is generally thought that they dull the senses, and cause sleepless nights attended with dreams. Hence it is that the bean has been condemned by Pythagoras; though, according to some, the reason for this denunciation was the belief which he entertained that the souls of the dead are enclosed in the bean: it is for this reason, too, that beans are used in the funereal banquets of the Parentalia. According to Varro, it is for a similar cause that the Flamen abstains from eating beans: in addition to which, on the blossom of the bean, there are certain letters of ill omen to be found.

There are some peculiar religious usages connected with the bean. It is the custom to bring home from the harvest a bean by way of auspice, which, from that circumstance, has the name of “referiva.” In sales by public auction, too, it is thought lucky to include a bean in the lot for sale. It is a fact, too, that the bean is the only one among all the grains that fills out at the increase of the moon, however much it may have been eaten away: it can never be thoroughly boiled in sea-water, or indeed any other water that is salt.

The bean is the first leguminous plant that is sown; that being done before the setting of the Vergiliæ, in order that it may pass the winter in the ground. Virgil recommends that it should be sown in spring, according to the usage of the parts of Italy near the Padus: but most people prefer the bean that has been sown early to that of only three months’ growth; for, in the former case, the pods as well as the stalk afford a most agreeable fodder for cattle. When in blossom more particularly, the bean requires water; but after the blossom has passed off, it stands in need of but very little. It fertilizes the ground in which it has been sown as well as any manure hence it is that in the neighbourhood of Thessaly and Macedonia, as soon as it begins to blossom, they turn up the ground.

The bean, too, grows wild in most countries, as in those islands of the Northern Ocean, for instance, which for that reason have been called by us the “Fabariæ.” In Mauritania, also, it is found in a wild state in various parts, but

so remarkably hard that it will never become soft by boiling.

In Egypt there is a kind of bean which grows upon a thorny stalk; for which reason the crocodiles avoid it, being apprehensive of danger to their eyes. This stalk is four cubits in length, and its thickness, at the very most, that of the finger: were it not for the absence of articulations in it, it would resemble a soft reed in appearance. The head is similar to that of the poppy, being of a rose colour: the beans enclosed in this head are not above thirty in number; the leaves are large, and the fruit is bitter and odoriferous. The root, however, is highly esteemed by the natives as a food, whether eaten raw or well boiled; it bears a strong resemblance to that of the reed. This plant grows also in Syria and Cilicia, and upon the banks of Lake Torone in Chalcidice.

CHAP. 31.

LENTILS. PEASE.

Among the leguminous plants the lentil is sown in the month of November, and the pea, among the Greeks. The lentil thrives best in a soil that is rather thin than rich, and mostly stands in need of dry weather. There are two kinds of lentil grown in Egypt; one of which is rounder and blacker than the other, which has a peculiar shape of its own. The name of this plant has been applied to various uses, and among others has given origin to our word “lenticula.” I find it stated in some authors that a lentil diet is productive of evenness of temper. The pea requires to be sown in a warm, sunny spot, and is ill able to endure cold; hence in Italy and the more rigorous climates, it is sown in the spring only, a light, loose soil being chosen for the purpose.

Detailed table of contents

CHAP. 32.

THE SEVERAL KINDS OF CHICK-PEASE.

The chick-pea is naturally salt, for which reason it is apt to scorch the ground, and should only be sown after it has been steeped a day in water. This plant presents considerable differences in reference to size, colour, form, and taste. One variety resembles in shape a ram's head, from which circumstance it has received the name of "arietinum;" there are both the white and the black arietinum. There is also the columbine chick-pea, by some known as the "pea of Venus;" it is white, round, and smooth, being smaller than the arietinum, and is employed in the observances of the night festivals or vigils. The chicheling vetch, too, is a diminutive kind of chick-pea, unequal and angular, like the pea. The chickpea that is the sweetest in flavour is the one that bears the closest resemblance to the fitch; the pod in the black and the red kinds is more firmly closed than in the white ones.

Detailed table of contents

CHAP. 33.

THE KIDNEY-BEAN.

The pod of the chick-pea is rounded, while in other leguminous plants it is long and broad, like the seed which it contains; in the pea, again, it is of a cylindrical form. In the case of the kidney-bean it is usual to eat the pod together with the seed. This last may be sown in all kinds of soils indifferently, between the ides of October and the calends of November. As soon as ever the leguminous plants begin to ripen, they ought to be plucked, for the pods will very soon open and the seed fall out, in which case it is very difficult to find: the same is the case, too, with the lupine. But before we pass on to the lupine, it will be as well to make some mention of the rape.

Detailed table of contents

CHAP. 34. (13.)

THE RAPE.

The Latin writers have only treated of this plant in a cursory manner, while those of Greece have considered it a little more attentively; though even they have ranked it among the garden plants. If, however, a methodical arrangement is to be strictly observed, it should be spoken of immediately after corn, or the bean, at all events; for next to these two productions, there is no plant that is of more extensive use. For, in the first place, all animals will feed upon it as it grows; and it is far from being the least nutritious plant in the fields for various kinds of birds, when boiled in water more particularly. Cattle, too, are remarkably fond of the leaves of rape; and the stalks and leaves, when in season, are no less esteemed as a food for man than the sprouts of the cabbage; these, too, when turned yellow and left to die in the barn, are even more highly esteemed than when green. As to the rape itself, it will keep all the better if left in its mould, after which it should be dried in the open air till the next crop is nearly ripe, as a resource in case of scarcity. Next to those of the grape and corn, this is the most profitable harvest of all for the countries that lie beyond the Padus. The rape is by no means difficult to please in soil, for it will grow almost anywhere, indeed where nothing else can be sown. It readily derives nutriment from fogs and hoar-frosts, and grows to a marvellous size; I have seen them weighing upwards of forty pounds. It is prepared for table among us in several ways, and is made to keep till the next crop, its Fermentation being prevented by preserving it in mustard. It is also tinted with no less than six colours in addition to its own, and with purple even; indeed, that which is used by us as food ought to be of no other colour.

The Greeks have distinguished two principal species of rape, the male and the female, and have discovered a method of obtaining them both from the same seed; for when it is sown thick, or in a hard, cloggy soil, the produce will be male. The smaller the seed the better it is in quality. There are three kinds of rape in all; the first is broad and flat, the second of a spherical shape, and the third, to which the name of "wild" rape has been given, throws out a long root, similar in appearance to a radish, with an angular, rough leaf, and an acrid juice, which, if extracted about harvest, and mixed with a woman's milk, is good for cleansing the eyes and improving defective sight. The colder the weather the sweeter they are, and the larger, it is generally thought; heat makes them run to leaf. The finest rape of all is that grown in the district of Nurslia: it is valued at as much as one sesterce per pound, and, in times of scarcity, two even. That of the next best quality is produced on Mount Algidus.

CHAP. 35.

THE TURNIP.

The turnip of Amiternum, which is pretty nearly of the same nature as the rape, thrives equally well in a cold soil. It is sown just before the calends of March, four sextarii of seed to the jugerum. The more careful growers recommend that the ground should be turned up five times before putting in the turnip, and four for rape, care being taken, in both cases, to manure it well. Rape, they say, will thrive all the better, if it is sown together with some chaff. They will have it, too, that the sower ought to be stripped, and that he should offer up a prayer while sowing, and say: "I sow this for myself and for my neighbours." The proper time for sowing both kinds is the period that intervenes between the festivals of the two divinities, Neptune and Vulcan. It is said, too — and it is the result of very careful observation — that these plants will thrive wonderfully well, if they are sown as many days after the festival of Neptune as the moon was old when the first snow fell the previous winter. They are sown in spring as well, in warm and humid localities.

Detailed table of contents

CHAP. 36. (14.)

THE LUPINE.

The lupine is the next among the leguminous plants that is in extensive use, as it serves for food for man in common with the hoofed quadrupeds. To prevent it from springing out of the pod while being gathered, and so lost, the best plan is to gather it immediately after a shower. Of all the seeds that are sown, there is not one of a more marvellous nature than this, or more favoured by the earth. First of all, it turns every day with the sun, and shows the hour to the husbandman, even though the weather should happen to be cloudy and overcast. It blossoms, too, no less than three times, and so attached is it to the earth, that it does not require to be covered with the soil; indeed, this is the only seed that does not require the earth to be turned up for sowing it. It thrives more particularly on a sandy, dry, and even gravelly soil; and requires no further care to be taken in its cultivation. To such a degree is it attached to the earth, that even though left upon a soil thickly covered with brambles, it will throw out a root amid the leaves and brakes, and so contrive to reach the ground. We have already stated that the soil of a field or vineyard is enriched by the growth of a crop of lupines; indeed, so far is it from standing in need of manure, that the lupines will act upon it as well as the very best. It is the only seed that requires no outlay at all, so much so, in fact, that there is no necessity to carry it even to the spot where it is sown; for it may be sown the moment it is brought from the threshing-floor: and from the fact that it falls from the pod of its own accord, it stands in need of no one to scatter it.

This is the very first grain sown and the last that is gathered, both operations generally taking place in the month of September; indeed, if this is not done before winter sets in, it is liable to receive injury from the cold. And then, besides, it may even be left with impunity to lie upon the ground, in case showers should not immediately ensue and cover it in, it being quite safe from the attacks of all animals, on account of its bitter taste: still, however, it is mostly covered up in a slight furrow. Among the thicker soils, it is attached to a red earth more particularly. In order to enrich this earth, it should be turned up just after the third blossom; but where the soil is sandy, after the second. Chalky and slimy soils are the only ones that it has an aversion to; indeed, it will never come to anything when sown in them. Soaked in warm water, it is used as a food, too, for man. One modius is a sufficient meal for an ox, and it is found to impart considerable vigour to cattle; placed, too, upon the abdomen of children, it acts as a remedy in certain cases. It is an excellent plan to season the lupine by smoking it; for when it is kept in a moist state, maggots are apt to attack the germ, and render it useless for reproduction. If cattle have eaten it off while in leaf, as a matter of necessity it should be ploughed in as soon as possible.

Detailed table of contents

CHAP. 37. (15.)

THE VETCH.

The vetch, too, enriches the soil, and its cultivation entails no labour on the agriculturist. It is sown after the ground has been but once turned up, and requires neither hoeing nor manuring; nothing at all, indeed, except harrowing there are three periods for sowing it; the first is about the setting of Arcturus, when it is intended for feeding cattle in the month of December, while in the blade; this crop, too, is the best of all for seed, for, although grazed upon, it will bear just as well. The second crop is sown in the month of January, and the last in March; this last being the best crop for fodder. Of all the seeds this is the one that thrives best in a dry soil; still, however, it manifests no repugnance to a shaded locality. This grain, if gathered when quite ripe, produces a chaff superior to that of any other. If sown near vines supported by trees, the vetch will draw away the juices from the vines, and make them languid.

Detailed table of contents

CHAP. 38.

THE FITCH.

The cultivation of the fitch, too, is attended with no difficulty. It requires weeding, however, more than the vetch. Like it, the fitch has certain medicinal properties; for we find the fact still kept in remembrance by some letters of his, that the late Emperor Augustus was cured by its agency. Five modii will sow as much ground as a yoke of oxen can plough in a day. If sown in the month of March, it is injurious, they say, to oxen: and when sown in autumn, it is apt to produce head-ache. If, however, it is put in the ground at the beginning of spring, it will be productive of no bad results.

[Detailed table of contents](#)

CHAP. 39. (16.)

SILICIA.

Silicia, or, in other words, fenugreek, is sown after alight ploughing merely, the furrows being no more than some four fingers in depth; the less the pains that are bestowed upon it the better it will thrive — a singular fact that there should be anything that profits from neglect. The kinds, however, that are known as “secale” and “farrago” require harrowing only.

Detailed table of contents

CHAP. 40.

SECALE OR ASIA.

The people of Taurinum, at the foot of the Alps, give to secale the name of “asia;” it is a very inferior grain, and is only employed to avert positive famine. It is prolific, but has a straw of remarkable thinness; it is also black and sombre-looking, but weighs extremely heavy. Spelt is mixed with this grain to modify its bitterness, and even then it is very disagreeable to the stomach. It will grow upon any soil, and yields a hundred-fold; it is employed also as a manure for enriching the land.

[Detailed table of contents](#)

CHAP. 41.

FARRAGO: THE CRACCA.

Farrago, a mixture made of the refuse of “far,” or spelt, is sown very thick, the vetch being sometimes mingled with it; in Africa, this mixture is sometimes made with barley. All these mixtures, however, are only intended for cattle, and the same is the case with the cracca a degenerate kind of leguminous plant. Pigeons, it is said, are so remarkably fond of this grain, that they will never leave the place where it has been given to them.

Detailed table of contents

CHAP. 42.

OCINUM: ERVILIA.

Among the ancients there was a sort of fodder, to which Cato gives the name of “ocinum;” it was employed by them to stop scouring in oxen. This was a mixture of various kinds of fodder, cut green before the frosts came on. Mamilius Sura, however, explains the term differently, and says that ten modii of beans, two of vetches, and the same quantity of ervilia, were mixed and sown in autumn on a jugerum of land. He states, also, that it is a still better plan to mix some Greek oats with it, the grain of which never falls to the ground; this mixture, according to him, was ocinum, and was usually sown as a food for oxen. Varro informs us that it received its name on account of the celerity with which it springs up, from the Greek ὠχέως, “quickly.”

Detailed table of contents

CHAP. 43.

LUCERNE.

Lucerne is by nature an exotic to Greece even, it having been first introduced into that country from Media, at the time of the Persian wars with King Darius; still it deserves to be mentioned among the very first of these productions. So superior are its qualities, that a single sowing will last more than thirty years. It resembles trefoil in appearance, but the stalk and leaves are articulated. The longer it grows in the stalk, the narrower is the leaf. Amphilochus has devoted a whole book to this subject and the cytissus. The ground in which it is sown, being first cleaned and cleared of stones, is turned up in the autumn, after which it is ploughed and harrowed. It is then harrowed a second and a third time, at intervals of five days; after which manure is laid upon it. This seed requires either a soil that is dry, but full of nutriment, or else a well-watered one. After the ground has been thus prepared, the seed is put in the month of May; for if sown earlier, it is in danger from the frosts. It is necessary to sow the seed very thick, so that all the ground may be occupied, and no room left for weeds to shoot up in the intervals; a result which may be secured by sowing twenty modii to the jugerum. The seed must be stirred at once with the rake, to prevent the sun from scorching it, and it should be covered over with earth as speedily as possible. If the soil is naturally damp or weedy, the lucerne will be overpowered, and the spot degenerate into an ordinary pasture; it is necessary, therefore, directly the crop is an inch in height, to disengage it from all weeds, by hand, in preference to the weeding-hook.

It is cut when it is just beginning to flower, and this is repeated as often as it throws out new blossoms; which happens mostly six times in the year, and four at the very least. Care should be taken to prevent it from running to seed, as it is much more valuable as fodder, up to the third year. It should be hoed in the spring, and cleared of all other plants; and in the third year the surface should be well worked with the weeding-hook. By adopting this method, the weeds will be effectually destroyed, though without detriment to the lucerne, in consequence of the depth of its roots. If the weeds should happen to get ahead of it, the only remedy is to turn it up repeatedly with the plough, until the roots of the weeds are thoroughly destroyed. This fodder should never be given to cattle to satiety, otherwise it may be necessary to let blood; it is best, too, when used while green. When dry, it becomes tough and ligneous, and falls away at last into a thin, useless dust. As to the cytissus, which also occupies the very foremost rank among the fodders, we have already spoken of it at sufficient length when describing the shrubs. It remains for us now to complete our account of all the cereals, and we shall here devote a portion of it to the diseases to which they are subject.

Detailed table of contents

CHAP. 44. (17.)

the DISEASES OF GRAIN: THE OAT.

The foremost feature of disease in wheat is the oat. Barley, too, will degenerate into the oat; so much so, in fact, that tile oat has become an equivalent for corn; for the people of Germany are in the habit of sowing it, and make their porridge of nothing else. This degeneracy is owing more particularly to humidity of soil and climate; and a second cause is a weakness in the seed, the result of its being retained too long in the ground before it makes its appearance above it. The same, too, will be the consequence, if the seed is decayed when put in the ground. This may be known, however, the moment it makes its appearance, from which it is quite evident that the defect lies in the root. There is another form of disease, too, which closely resembles the oat, and which supervenes when the grain, already developed to its full size, but not ripe, is struck by a noxious blast, before it has acquired its proper body and strength; in this case, the seed pines away in the ear, by a kind of abortion, as it were, and totally disappears.

The wind is injurious to wheat and barley, at three periods of the year in particular: when they are in blossom, directly the blossom has passed off, and just as the seed is beginning to ripen. In this last case, the grain wastes away, while in the two former ones it is prevented from being developed. Gleams of sunshine, every now and then, from the midst of clouds, are injurious to corn. Maggots, too, breed in the roots, when the rains that follow the seed-time are succeeded by a sudden heat, which encloses the humidity in the ground. Maggots make their appearance, also, in the grain, when the ear ferments through heat succeeding a fall of rain. There is a small beetle, too, known by the name of “cantharis,” which eats away the blade. All these insects die, however, as soon as their nutriment fails them. Oil, pitch, and grease are prejudicial to grain, and care should be taken not to let them come in contact with the seed that is sown. Rain is only beneficial to grain while in the blade; it is injurious to wheat and barley while they are in blossom, but is not detrimental to the leguminous plants, with the exception of the chick-pea. When grain is beginning to ripen, rain is injurious, and to barley in particular. There is a white grass that grows in the fields, very similar to panic in appearance, but fatal to cattle. As to darnel, the tribulus, the thistle, and the burdock, I can consider them, no more than the bramble, among the maladies that attack the cereals, but rather as so many pests inflicted on the earth. Mildew, a malady resulting from the inclemency of the weather, and equally attacking the vine and corn, is in no degree less injurious. It attacks corn most frequently in localities which are exposed to dews, and in vallies which have not a thorough draught for the wind; windy and elevated spots, on the other hand, are totally exempt from it. Another evil, again, in corn, is over-luxuriance, when it falls

to the ground beneath the weight of the grain. One evil, however, to which all crops in common, the chick-pea even, are exposed, is the attacks of the caterpillar, when the rain, by washing away the natural saltiness of the vegetation, makes it all the more tempting for its sweetness.

There is a certain plant, too, which kills the chick-pea and the fitch, by twining around them; the name of it is “*orobanche*.” In a similar manner, also, wheat is attacked by darnel, barley by a long-stalked plant, called “*ægilops*,” and the lentil by an axe-leaved grass, to which, from the resemblance of the leaf, the Greeks have given the name of “*pelecinon*.” All these plants, too, kill the others by entwining around them. In the neighbourhood of Philippi, there is a plant known as *ateramon*, which grows in a rich soil, and kills the bean, after it has been exposed, while wet, to the blasts of a certain wind: when it grows in a thin, light soil, this plant is called “*teramon*.” The seed of darnel is extremely minute, and is enclosed in a prickly husk. If introduced into bread, it will speedily produce vertigo; and it is said that in Asia and Greece, the bath-keepers, when they want to disperse a crowd of people, throw this seed upon burning coals. The phalangium, a diminutive insect of the spider genus, breeds in the fitch, if the winter happens to be wet. Slugs, too, breed in the vetch, and sometimes a tiny snail makes its way out of the ground, and eats it away in a most singular manner.

These are pretty nearly all the maladies to which grain is subject.

Detailed table of contents

CHAP. 45.

THE BEST REMEDIES FOR THE DISEASES OF GRAIN.

The best remedy for these maladies, so long as grain is in the blade, is the weeding-hook, and, at the moment of sowing, ashes. As to those diseases which develop themselves in the seed and about the root, with due care precautions may be effectually employed against them. It is generally supposed that if seed has been first steeped in wine, it will be less exposed to disease. Virgil recommends that beans should be drenched with nitre and amurca of olives; and he says that if this is done, they will be all the larger. Some persons, again, are of opinion, that they will grow of increased size, if the seed is steeped for three days before it is sown in a solution of urine and water. If the ground, too, is hoed three times, a modius of beans in the pod, they say, will yield not less than a modius of shelled beans. Other seeds, again, it is said, will be exempt from the attacks of maggots, if bruised cypress leaves are mixed with them, or if they are sown just at the moon's conjunction. Many persons, for the more effectual protection of millet, recommend that a bramble-frog should be carried at night round the field before the hoeing is done, and then buried in an earthen vessel in the middle of it. If this is done, they say, neither sparrows nor worms will attack the crop. The frog, however, must be disinterred before the millet is cut; for if this is neglected, the produce will be bitter. It is pretended, too, that all seeds which have been touched by the shoulders of a mole are remarkably productive.

Democritus recommends that all seeds before they are sown should be steeped in the juice of the herb known as "aizoüm," which grows on tiles or shingles, and is known to us by the Latin name of "sedum" or "digitellum." If blight pre- vails, or if worms are found adhering to the roots, it is a very common remedy to sprinkle the plants with pure amurca of olives without salt, and then to hoe the ground. If, however, the crop should be beginning to joint, it should be stubbed at once, for fear lest the weeds should gain the upper hand. I know for certain that flights of starlings and sparrows, those pests to millet and panic, are effectually driven away by means of a certain herb, the name of which is unknown to me, being buried at the four corners of the field: it is a wonderful thing to relate, but in such case not a single bird will enter it. Mice are kept away by the ashes of a weasel or a cat being steeped in water and then thrown upon the seed, or else by using the water in which the body of a weasel or a cat has been boiled. The odour, however, of these animals makes itself perceived in the bread even; for which reason it is generally thought a better plan to steep the seed in ox-gall. As for mildew, that greatest curse of all to corn, if branches of laurel are fixed in the ground, it will pass away from the field into the leaves of the laurel. Over-luxuriance in corn is repressed by the teeth of cattle, but only while it is in the blade; in

which case, if depastured upon ever so often, no injury to it when in the ear will be the result. If the ear, too, is once cut off, the grain, it is well known, will assume a larger form, but will be hollow within and worthless, and if sown, will come to nothing.

At Babylon, however, they cut the blade twice, and then let the cattle pasture on it a third time, for otherwise it would run to nothing but leaf. Even then, however, so fertile is the soil, that it yields fifty, and, indeed, with care, as much as a hundred, fold. Nor is the cultivation of it attended with any difficulty, the only object being to let the ground be under water as long as possible, in order that the extreme richness and exuberance of the soil may be modified. The Euphrates, however, and the Tigris do not deposit a slime, in the same way that the Niles does in Egypt, nor does the soil produce vegetation spontaneously; but still, so great is the fertility, that, although the seed is only trodden in with the foot, a crop springs up spontaneously the following year. So great a difference in soils as this, reminds me that I ought to take this opportunity of specifying those which are the best adapted for the various kinds of grain.

Detailed table of contents

CHAP. 46.

THE CROPS THAT SHOULD BE SOWN IN THE DIFFERENT SOILS.

This, then, is the opinion expressed by Cato on the subject: “In a dense and fertile soil wheat should be sown: but if the locality is subject to fogs, rape, radishes, millet, and panic. Where the land is cold and moist, sowing should be commenced earlier; but where it is hot, at a later period. In a red, black, or gravelly soil, provided it is not watery, lupines should be sown; but in chalk, red earth, or a watery soil, spelt. Where a locality is dry, free from weeds, and not overshadowed, wheat should be put; in; and where the soil is strong and powerful, beans. Vetches should be grown in a soil as free from water and weeds as possible; while wheat and winter wheat are best adapted to an open, elevated locality, fully exposed to the warmth of the sun, the lentil thrives best in a meager, red earth, free from weeds. Barley is equally suited for fallow land and for a soil that is not intended to be fallow, and three-month wheat, for a soil upon which a crop of ordinary wheat would never ripen, but strong enough to bear.”

The following, too, is sound advice: Those plants should be sown in a thin soil which do not stand in need of much nutriment, the cytusus, for instance, and such of the leguminous plants, with the exception of the chick-pea, as are taken up by the roots and not cut. From this mode of gathering them—“legers” — the leguminous derive their name. Where it is a rich earth, those plants should be grown which require a greater proportion of nutriment, codeword for instance, wheat, winter-wheat, and flax. The result, then, will be, that a light soil will be given to barley — the root of that grain standing in need of less nutriment — while a more dense, though easily-worked soil, will be assigned to wheat. In humid localities spelt should be sown in preference to wheat; but where the soil is of moderate temperature, either wheat or barley may be grown. Declivities produce a stronger growth of wheat, but in smaller quantities. Spelt and winter-wheat adopt a moist, cretaceous soil in preference to any other.

(18.) The only occasion on which there ever was a prodigy connected with grain, at least that I am aware of, was in the consulship of P. Ælias and Census Cornelius, the year in which Hannibal was vanquished: on that occasion, we find it stated, corn was seen growing upon trees.

CHAP. 47.

THE DIFFERENT SYSTEMS OF CULTIVATION EMPLOYED BY VARIOUS NATIONS.

As we have now spoken at sufficient length of the several varieties of grain and soil, we shall proceed to treat of the methods adopted in tilling the ground, taking care, in the very first place, to make mention of the peculiar facilities enjoyed by Egypt in this respect. In that country, performing the duties of the husbandman, the Nile begins to overflow, as already stated, immediately after the summer solstice or the new moon, gradually at first, but afterwards with increased impetuosity, as long as the sun remains in the sign of Leo, When the sun has passed into Virgo, the impetuosity of the overflow begins to slacken, and when he has entered Libra the river subsides. Should it not have exceeded twelve cubits in its overflow, famine is the sure result; and this is equally the case if it should chance to exceed sixteen; for the higher it has risen, the more slowly it subsides, and, of course, the seedtime is impeded in proportion. It was formerly a very general belief that immediately upon the subsiding of the waters the Egyptians were in the habit of driving herds of swine over the ground, for the purpose of treading the seed into the moist soil — and it is my own impression that this was done in ancient times. At the present day even, the operation is not attended with much greater labour. It is well known, however, that the seed is first laid upon the slime that has been left by the river on its subsidence, and then ploughed in; this being done at the beginning of November. After this is done, a few persons are employed in stubbing, an operation known there as “botanismos.” The rest of the labourers, however, have no occasion to visit the land again till a little before the calends of April, and then it is with the reaping-hook. The harvest is completed in the month of May. The stem is never so much as a cubit in length, as there is a stratum of sand beneath the slime, from which last alone the grain receives its support. The best wheat of all is that of the region of Thebais, Egypt being of a marshy character.

The method adopted at Seleucia in Babylonia is very similar to this, but the fertility there is still greater, owing to the overflow of the Euphrates and Tigris, the degree of irrigation being artificially modified in those parts. In Syria, too, the furrows are made extremely light, while in many parts of Italy, again, it takes as many as eight oxen to pant and blow at a single plough. All the operations of agriculture, but this in particular, should be regulated by the oracular precept— “Remember that every locality has its own tendencies.”

CHAP. 48.

THE VARIOUS KINDS OF PLOUGHS.

Ploughs are of various kinds. The coulter is the iron part that cuts up the dense earth before it is broken into pieces, and traces beforehand by its incisions the future furrows, which the share, reversed, is to open out with its teeth. Another kind — the common plough-share — is nothing more than a lever, furnished with a pointed beak; while another variety, which is only used in light, easy soils, does not present an edge projecting from the share-beam throughout, but only a small point at the extremity. In a fourth kind again, this point is larger and formed with a cutting edge; by the agency of which implement, it both cleaves the ground, and, with the sharp edges at the sides, cuts up the weeds by the roots. There has been invented, at a comparatively recent period, in that part of Gaul known as Rhætia, a plough with the addition of two small wheels, and known by the name of “plaumorati.” The extremity of the share in this has the form of a spade: it is only used, however, for sowing in cultivated lands, and upon soils which are nearly fallow. The broader the plough-share, the better it is for turning up the clods of earth. Immediately after ploughing, the seed is put into the ground, and then harrows with long teeth are drawn over it. Lands which have been sown in this way require no hoeing, but two or three pairs of oxen are employed in ploughing. It is a fair estimate to consider that a single yoke of oxen can work forty jugera of land in the year, where the soil is light, and thirty where it is stubborn.

Detailed table of contents

CHAP. 49. (19,)

THE MODE OF PLOUGHING.

In ploughing, the most rigid attention should be paid to the oracular precepts given by Cato on the subject. "What is the essence of good tillage? Good ploughing. What is the second point? Ploughing again. What is the third point? Manuring. Take care not to make crooked furrows. Be careful to plough at the proper time." In warm localities it is necessary to open the ground immediately after the winter solstice, but where it is coke, directly after the vernal equinox: this, too, should be done sooner in dry districts than in wet ones, in a dense soil than a loose one, in a rich land than a meagre one. In countries where the summers are hot and oppressive, the soil cretaceous or thin, it is the best plan to plough between the summer solstice and the autumnal equinox. Where, on the other hand, the heat is moderate, with frequent falls of rain, and the soil rich and full of vegetation, the ploughing should be done during the prevalence of the heat. A deep, heavy soil, again, should be ploughed in winter; but one that is very thin and dry, only just before putting in the seed.

Tillage, too, has its own particular rules — Never touch the ground while it is wet and cloggy; plough with all your might; loosen the ground before you begin to plough. This method has its advantages, for by turning up the clods the roots of the weeds are killed. Some persons recommend that in every case the ground should be turned up immediately after the vernal equinox. Land that has been ploughed once in spring, from that circumstance has the name of "vervactum." This, too, is equally necessary in the case of fallow land, by which term is meant land that is sown only in alternate years. The oxen employed in ploughing should be harnessed as tightly as possible, to make them plough with their heads up; attention paid to this point will prevent them from galling the neck. If it is among trees and vines that you are ploughing, the oxen should be muzzled, to prevent them from eating off the tender buds. There should be a small bill-hook, too, projecting from the plough-tail, for the purpose of cutting up the roots; this plan being preferable to that of turning them up with the share, and so straining the oxen. When ploughing, finish the furrow at one spell, and never stop to take breath in the middle.

It is a fair day's work to plough one jugerum, for the first time, nine inches in depth; and the second time, one jugerum and a half — that is to say, if it is an easy soil. If this, however, is not the case, it will take a day to turn up half a jugerum for the first time, and a whole jugerum the second; for Nature has set limits to the powers of animals even. The furrows should be made, in every case, first in a straight line, and then others should be drawn, crossing them obliquely. Upon a hill-side the furrows are drawn transversely only, the point of the share inclining upwards at one moment and downwards at another.

Man, too, is so well fitted for labour, that he is able to supply the place of the ox even; at all events, it is without the aid of that animal that the mountain tribes plough, having only the hoe to help them.

The ploughman, unless he stoops to his work, is sure to prevaricate, a word which has been transferred to the Forum, as a censure upon those who transgress — at any rate, let those be on their guard against it, where it was first employed. The share should be cleaned every now and then with a stick pointed with a scraper. The ridges that are left between every two furrows, should not be left in a rough state, nor should large clods be left protruding from the ground. A field is badly ploughed that stands in need of harrowing after the seed is in; but the work has been properly done, when it is impossible to say in which direction the share has gone. It is a good plan, too, to leave a channel every now and then, if the nature of the spot requires it, by making furrows of a larger size, to draw off the water into the drains.

(20.) After the furrows have been gone over again transversely, the clods are broken, where there is a necessity for it, with either the harrow or the rake; and this operation is repeated after the seed has been put in. This last harrowing is done, where the usage of the locality will allow of it, with either a toothed harrow, or else a plank attached to the plough. This operation of covering in the seed is called “*lirare*,” from which is derived the word “*deliratio*.” Virgil, it is generally thought, intends to recommend sowing after *four* ploughings, in the passage where he says that land will bear the best crop, which has twice felt the sun and twice the cold. Where the soil is dense, as in most parts of Italy, it is a still better plan to go over the ground five times before sowing; in Etruria, they give the land as many as nine ploughings first. The bean, however, and the vetch may be sown with no risk, without turning up the land at all; which, of course, is so much labour saved.

We must not here omit to mention still one other method of ploughing, which the devastations of warfare have suggested in Italy that lies beyond the Padus. The Salassi, when ravaging the territories which lay at the foot of the Alps, made an attempt to lay waste the crops of panic and millet that were just appearing above the ground. Finding, however, that Nature resisted all their endeavours, they passed the plough over the ground, the result of which was that the crops were more abundant than ever; and this it was that first taught us the method of ploughing in, expressed by the word “*artrare*,” otherwise “*aratrare*,” in my opinion the original form. This is done either just as the stem begins to develope itself, or else when it has put forth as many as two or three leaves. Nor must we withhold from the reader a more recent method, which was discovered the year but one before this, in the territory of the Treviri. The crops having been nipped by the extreme severity of the winter, the people sowed the land over again in the month of March, and had a most abundant harvest.

We shall now proceed to a description of the peculiar methods employed in cultivating each description of grain.

Detailed table of contents

CHAP. 50. (21.)

THE METHODS OF HARROWING, STUBBING, AND HOEING, EMPLOYED FOR EACH DESCRIPTION OF GRAIN. THE USE OF THE HARROW.

For winter wheat, spelt, wheat, zeo, and barley, harrow, hoe and stub upon the days which will be mentioned in the sequel. A single hand per jugerum will be quite enough for any one of these kinds of grain. The operation of hoeing loosens the ground in spring when it has been hardened and saddened by the rigours of the winter, and admits the early sun to the interior. In hoeing, every care must be taken not to go beneath the roots of the corn; in the case of wheat, zeo, and barley, it is best to give a couple of hoeings. Stubbing, when the crop is just beginning to joint, cleanses it of all noxious weeds, disengages the roots of the corn, and liberates the growing blade from the clods. Among the leguminous plants, the chick-pea requires the same treatment that spelt does. The bean requires no stubbing, being quite able of itself to overpower all weeds; the lupine, too, is harrowed only. Millet and panic are both harrowed and hoed; but this operation is never repeated, and they do not require stubbing. Fenugreek and the kidney-bean require harrowing only.

There are some kinds of ground, the extreme fertility of which obliges the grower to comb down the crops while in the blade — this is done with a sort of harrow armed with pointed iron teeth — and even then he is obliged to depasture cattle upon them. When, however, the blade has been thus eaten down, it stands in need of hoeing to restore it to its former vigour.

But in Bactria, and at Cyrenæ in Africa, all this trouble has been rendered quite unnecessary by the indulgent benignity of the climate, and after the seed is in, the owner has no occasion to return to the field till the time has come for getting in the harvest. In those parts the natural dryness of the soil prevents noxious weeds from springing up, and, aided by the night dews alone, the soil supplies its nutriment to the grain. Virgil recommends that the ground should be left to enjoy repose every other year; and this, no doubt, if the extent of the farm will admit of it, is the most advantageous plan. If, however, circumstances will not allow of it, spelt should be sown upon the ground that has been first cropped with lupines, vetches, or beans; for all these have a tendency to make the soil more fertile. We ought to remark here more particularly, that here and there certain plants are sown for the benefit of others, although, as already stated in the preceding Book, not to repeat the same thing over again, they are of little value themselves. But it is the nature of each soil that is of the greatest importance.

CHAP. 51. (22.)

EXTREME FERTILITY OF SOIL.

There is a city of Africa, situate in the midst of the sands as you journey towards the Syrtes and Great Leptis, Tacape by name. The soil there, which is always well-watered, enjoys a degree of fertility quite marvellous. Through this spot, which extends about three miles each way, a spring of water flows — in great abundance it is true — but still, it is only at certain hours that its waters are distributed among the inhabitants. Here, beneath a palm of enormous size, grows the olive, beneath the olive the fig, beneath the fig, again, the pomegranate, beneath the pomegranate the vine, and beneath the vine we find sown, first wheat, then the leguminous plants, and after them garden herbs — all in the same year, and all growing beneath another's shade. Four cubits square of this same ground — the cubit being measured with the fingers contracted and not extended — sell at the rate of four denarii. But what is more surprising than all, is the fact that here the vine bears twice, and that there are two vintages in the year. Indeed, if the fertility of the soil were not distributed in this way among a multitude of productions, each crop would perish from its own exuberance: as it is, there is no part of the year that there is not some crop or other being gathered in; and yet, it is a well-known fact, that the people do nothing at all to promote this fruitfulness.

There are very considerable differences, too, in the nature of water, as employed for the purposes of irrigation. In the province of Gallia Narbonensis there is a famous fountain, Orge by name; within it there grow plants which are sought for with such eagerness by the cattle, that they will plunge over head into the water to get at them; it is a well ascertained fact, however, that these plants, though growing in the water, receive their nutriment only from the rains that fall. It is as well then that every one should be fully acquainted with the nature, not only of the soil, but of the water too.

Detailed table of contents

CHAP. 52. (23.)

THE METHOD OF SOWING MORE THAN ONCE IN THE YEAR.

If the soil is of that nature which we have already spoken of as “tender,” after a crop of barley has been grown upon it, millet may be sown, and after the millet has been got in, rape. In succession to these, again, barley may be put in, or else wheat, as in Campania; and it will be quite enough, in such case, to plough the ground when the seed is sown. There is another rotation again — when the ground has been cropped with spelt, it should lie fallow the four winter months; after which, spring beans should be put in, to keep it occupied till the time comes for cropping it with winter beans. Where the soil is too rich, it may lie fallow one year, care being taken after sowing it with corn to crop it with the leguminous plants the third year. Where, on the other hand, it is too thin, the land should lie fallow up to the third year even. Some persons recommend that corn should never be sown except in land which has lain fallow the year before.

CHAP. 53.

THE MANURING OF LAND.

The proper method of manuring is here a very important subject for consideration — we have already treated of it at some length in the preceding Book. The only point that is universally agreed upon is, that we must never sow without first manuring the ground; although in this respect even there are certain rules to be observed. Millet, panic, rape, and turnips should never be sown in any but a manured soil. If, on the other hand, the land is not manured, sow wheat there in preference to barley. The same, too, with fallow lands; though in these it is generally recommended that beans should be sown. It should be remembered, however, that wherever beans are sown, the land should have been manured at as recent a period as possible. If it is intended to crop ground in autumn, care must be taken to plough in manure in the month of September, just after rain has fallen. In the same way, too, if it is intended to sow in spring, the manure should be spread in the winter. It is the rule to give eighteen cart-loads of manure to each jugerum, and to spread it well before ploughing it in, or sowing the seed. If this manuring, however, is omitted, it will be requisite to spread the land with aviary dust just before hoeing is commenced. To clear up any doubts with reference to this point, I would here observe that the fair price for a cart-load of manure is one denarius; where, too, sheep furnish one cart-load, the larger cattle should furnish ten: unless this result is obtained, it is a clear proof that the husbandman has littered his cattle badly.

There are some persons who are of opinion that the best method of manuring land is to pen sheep there, with nets erected to prevent them from straying. If land is not manured, it will get chilled; but if, on the other hand, it is over-manured, it becomes burnt up: it is a much better plan, too, to manure little and often than in excess. The warmer the soil is by nature, the less manure it requires.

Detailed table of contents

CHAP. 54. (24.)

HOW TO ASCERTAIN THE QUALITY OF SEED.

The best seed of all is that which is of the last year's growth. That which is two years old is inferior, and three the worst of all — beyond that, it is unproductive. The same definite rule which applies to one kind of seed is applicable to them all: the seed which falls to the bottom on the threshing-floor, should be reserved for sowing, for being the most weighty it is the best in quality: there is no better method, in fact, of ascertaining its quality. The grains of those ears which have intervals between the seed should be rejected. The best grain is that which has a reddish hue, and which, when broken between the teeth, presents the same colour; that which has more white within is of inferior quality. It is a well-known fact that some lands require more seed than others, from which circumstance first arose a superstition that exists among the peasantry; it is their belief that when the ground demands the seed with greater avidity than usual, it is famished, and devours the grain. It is consistent with reason to put in the seed where the soil is humid sooner than elsewhere, to prevent the grain from rotting in the rain: on dry spots it should be sown later, and just before the fall of a shower, so that it may not have to lie long without germinating and so come to nothing. When the seed is put in early it should be sown thick, as it is a considerable time before it germinates; but when it is put in later, it should be sown thinly, to prevent it from being suffocated. There is a certain degree of skill, too, required in scattering the seed evenly; to ensure this, the hand must keep time with the step, moving always with the right foot. There are certain persons, also, who have a secret method of their own, having been born with a happy hand which imparts fruitfulness to the grain. Care should be taken not to sow seed in a warm locality which has been grown in a cold one, nor should the produce of an early soil be sown in a late one. Those who give advice to the contrary have quite misapplied their pains.

Detailed table of contents

CHAP. 55.

WHAT QUANTITY OF EACH KIND OF GRAIN IS REQUISITE FOR SOWING A JUGEBRUM.

In a soil of middling quality, the proper proportion of seed is five modii of wheat or winter-wheat to the jugerum, ten of spelt or of seed-wheat — that being the name which we have mentioned as being given to one kind of wheat — six of barley, one-fifth more of beans than of wheat, twelve of vetches, three of chick-pease, chicheling vetches, and pease, ten of lupines, three of lentils — (these last, however, it is said, must be sown with dry manure) — six of fitches, six of fenugreek, four of kidney-beans, twenty of hay grass, and four sextarii of millet and panic. Where the soil is rich, the proportion must be greater, where it is thin, less.

There is another distinction, too, to be made; where the soil is dense, cretaceous, or moist, there should be six modii of wheat or winter-wheat to the jugerum, but where the land is loose, dry, and prolific, four will be enough. A meagre soil, too, if the crop is not very thinly sown, will produce a diminutive, empty ear. Rich lands give a number of stalks to each grain, and yield a thick crop from only a light sowing. The result, then, is, that from four to six modii must be sown, according to the nature of the soil; though there are some who make it a rule that five modii is the proper proportion for sowing, neither more nor less, whether it is a densely-planted locality, a declivity, or a thin, meagre soil. To this subject bears reference an oracular precept which never can be too carefully observed— “Don’t rob the harvest.” Attius, in his Praxidicus, has added that the proper time for sowing is, when the moon is in Aries, Gemini, Leo, Libra, and Aquarius. Zoroaster says it should be done when the sun has passed twelve degrees of Scorpio, and the moon is in Taurus.

Detailed table of contents

CHAP. 56.

THE PROPER TIMES FOR SOWING.

We now come to a subject which has been hitherto deferred by us, and which requires our most careful attention — the proper times for sowing. This is a question that depends in a very great degree upon the stars; and I shall therefore make it my first care to set forth all the opinions that have been written in reference to the subject. Hesiod, the first writer who has given any precepts upon agriculture, speaks of one period only for sowing — the setting of the Vergiliæ: but then he wrote in Bœotia, a country of Hellas, where, as we have already stated, they are still in the habit of sowing at that period.

It is generally agreed by the most correct writers, that with the earth, as with the birds and quadrupeds, there are certain impulses for reproduction; and the epoch for this is fixed by the Greeks at the time when the earth is warm and moist. Virgil says that wheat and spelt should be sown at the setting of the Vergiliæ, barley between the autumnal equinox and the winter solstice, and vetches, kidney-beans, and lentils at the setting of Boötes: it is of great importance, therefore, to ascertain the exact days of the rising and setting of these constellations, as well as of the others. There are some, again, who recommend the sowing to be done before the setting of the Vergiliæ, but only in a dry soil, and in those provinces where the weather is hot; for the seed, they say, if put in the ground will keep, there being no moisture to spoil it, and within a single day after the next fall of rain, will make its appearance above ground. Others, again, are of opinion that sowing should begin about seven days after the setting of the Vergiliæ, a period which is mostly followed by rain. Some think that cold soils should be sown immediately after the autumnal equinox, and a warm soil later, so that the blade may not put forth too luxuriantly before winter.

It is universally agreed, however, that the sowing should not be done about the period of the winter solstice; for this very good reason — the winter seeds, if put in before the winter solstice, will make their appearance above ground on the seventh day, whereas, if they are sown just after it, they will hardly appear by the fortieth. There are some, however, who begin very early, and have a saying to justify their doing so, to the effect that if seed sown too early often disappoints, seed put in too late always does so. On the other hand, again, there are some who maintain that it is better to sow in spring than in a bad autumn; and they say that if they find themselves obliged to sow in spring, they would choose the period that intervenes between the prevalence of the west winds and the vernal equinox. Some persons, however, take no notice of the celestial phenomena, and only regulate their movements by the months. In spring they put in flax, the oat, and the poppy, up to the feast of the Quinquatria, as we find done at the present day by the people of Italy beyond

the Padus. There, too, they sow beans and winter-wheat in the month of November, and spelt at the end of September, up to the ides of October: others, however, sow this last after the ides of October, as late as the calends of November.

The persons who do this take no notice, consequently, of the phænomena of Nature, while others, again, lay too much stress upon them, and hence, by these refined subtleties and distinctions, only add to their blindness; for here are ignorant rustics, not only dealing with a branch of learning, but that branch astronomy! It must still, however, be admitted that the observation of the heavens plays a very important part in the operations of agriculture; and Virgil, we find, gives it as his advice, that before any thing else, we should learn the theory of the winds, and the revolutions of the stars; for, as he says, the agriculturist, no less than the mariner, should regulate his movements thereby. It is an arduous attempt, and almost beyond all hope of success, to make an endeavour to introduce the divine science of the heavens to the uninformed mind of the rustic; still, however, with a view to such vast practical results as must be derived from this kind of knowledge, I shall make the attempt. There are some astronomical difficulties, however, which have been experienced by the learned even, that ought to be first submitted for consideration, in order that the mind may feel some encouragement on abandoning the study of the heavens, and may be acquainted with facts at least, even though it is still unable to see into futurity.

[Detailed table of contents](#)

CHAP. 57. (25.)

ARRANGEMENT OF THE STARS ACCORDING TO THE TERRESTRIAL DAYS AND NIGHTS.

In the first place, it is almost an utter impossibility to calculate with a fair degree of accuracy the days of the year and the movements of the sun. To the three hundred and sixty-five days there are still to be added the intercalary days, the result of the additional quarters of a day and night: hence it is, that it is found impossible to ascertain with exactness the proper periods for the appearance of the stars. To this we must add, too, a certain degree of uncertainty connected with these matters, that is universally admitted; thus, for instance, bad and wintry weather will often precede, by several days, the proper period for the advent of that season, a state of things known to the Greeks as *προχειμάζειν*; while at another time, it will last longer than usual, a state of circumstances known as *ἐπχειμάζειν*. The effects, too, of the changes that take place in the seasons will sometimes be felt later, and at other times earlier, upon their reaching the face of the earth; and we not unfrequently hear the remark made, upon the return of fine weather, that the action of such and such a constellation is now completed. And then, again, as all these phænomena depend upon certain stars, arranged and regulated in the vault of heaven, we find intervening, in accordance with the movements of certain stars, hailstorms and showers, themselves productive of no slight results, as we have already observed, and apt to interfere with the anticipated regular recurrence of the seasons. Nor are we to suppose that these disappointments fall upon the human race only, for other animated beings, as well as ourselves, are deceived in regard to them, although endowed with even a greater degree of sagacity upon these points than we are, from the fact of their very existence depending so materially upon them. Hence it is, that we sometimes see the summer birds killed by too late or too early cold, and the winter birds by heat coming out of the usual season. It is for this reason, that Virgil has recommended us to study the courses of the planets, and has particularly warned us to watch the passage of the cold star Saturn.

There are some who look upon the appearance of the butterfly as the surest sign of spring, because of the extreme delicacy of that insect. In this present year, however, in which I am penning these lines, it has been remarked that the flights of butterflies have been killed three several times, by as many returns of the cold; while the foreign birds, which brought us by the sixth of the calends of February every indication of an early spring, after that had to struggle against a winter of the greatest severity. In treating of these matters, we have to meet a twofold difficulty: first of all, we have to ascertain whether or not the celestial phænomena are regulated by certain laws, and then we have to seek how to reconcile those laws with apparent facts. We must, however, be more particularly careful to take into account the convexity of the

earth, and the differences of situation in the localities upon the face of the globe; for hence it is, that the same constellation shows itself to different nations at different times, the result being, that its influence is by no means perceptible everywhere at the same moment. This difficulty has been considerably enhanced, too, by various authors, who, after making their observations in different localities, and indeed, in some instances, in the same locality, have yet given us varying or contradictory results.

There have been three great schools of astronomy, the Chaldæan, the Ægyptian, and the Grecian. To these has been added a fourth school, which was established by the Dictator Cæsar among ourselves, and to which was entrusted the duty of regulating the year in conformity with the sun's revolution, under the auspices of Sosigenes, an astronomer of considerable learning and skill. His theory, too, upon the discovery of certain errors, has since been corrected, no intercalations having been made for twelve successive years, upon its being found that the year which before had anticipated the constellations, was now beginning to fall behind them. Even Sosigenes himself, too, though more correct than his predecessors, has not hesitated to show, by his continual corrections in the three several treatises which he composed, that he still entertained great doubts on the subject. The writers, too, whose names are inserted at the beginning of this work, have sufficiently revealed the fact of these discrepancies, the opinions of one being rarely found to agree with those of another. This, however, is less surprising in the case of those whose plea is the difference of the localities in which they wrote. But with reference to those who, though living in the same country, have still arrived at different results, we shall here mention one remarkable instance of discrepancy. Hesiod — for under his name, also, we have a treatise extant on the Science of the Stars — has stated that the morning setting of the Vergiliæ takes place at the moment of the autumnal equinox; whereas Thales, we find, makes it the twenty-fifth day after the equinox, Anaximander the twenty-ninth, and Euctemon the forty-eighth.

As for ourselves, we shall follow the calculations made by Julius Cæsar, which bear reference more particularly to Italy; though at the same time, we shall set forth the dicta of various other writers, bearing in mind that we are treating not of an individual country, but of Nature considered in her totality. In doing this, however, we shall name, not the writers themselves, for that would be too lengthy a task, but the countries in reference to which they speak. The reader must bear in mind, then, that for the sake of saving space, under the head of Attica, we include the islands of the Cyclades as well; under that of Macedonia, Magnesia and Thracia; under that of Egypt, Phœnice, Cyprus, and Cilicia; under that of Bœotia, Locris, Phocis, and the adjoining countries; under that of Hellespont, Chersonesus, and the contiguous parts as far as Mount Athos; under that of Ionia, Asia and the islands of Asia; under that of Peloponnesus, Achaia, and the regions lying to the west of it. Chaldæa, when mentioned, will signify Assyria and Babylonia, as well.

My silence as to Africa, Spain, and the provinces of Gaul, will occasion no surprise, from the fact that no one has published any observations made upon the stars in those countries. Still, however, there will be no difficulty in calculating them, even for these regions as well, on reference being made to the parallels which have been set forth in the Sixth Book. By adopting this course, an accurate acquaintance may be made with the astronomical relations, not only of individual nations, but of cities even as well. By taking the circular parallels which we have there appended to the several portions of the earth respectively, and applying them to the countries in question, that are similarly situate, it will be found that the rising of the heavenly bodies will be the same for all parts within those parallels, where the shadows projected are of equal length. It is also deserving of remark, that the seasons have their periodical recurrences, without any marked difference, every four years, in consequence of the influence of the sun, and that the characteristics of the seasons are developed in excess every eighth year, at the revolution of every hundredth moon.

Detailed table of contents

CHAP. 58.

THE RISING AND SETTING OF THE STARS.

The whole of this system is based upon the observation of three branches of the heavenly phænomena, the rising of the constellations, their setting, and the regular recurrence of the seasons. These risings and settings may be observed in two different ways: — The stars are either concealed, and cease to be seen at the rising of the sun, or else present themselves to our view at his setting — this last being more generally known by the name of “emersion” than of “rising,” while their disappearance is rather an “occultation” than a “setting.” — Considered, again, in another point of view, when upon certain days they begin to appear or disappear, at the setting or the rising of the sun, as the case may be, these are called their morning or their evening settings or risings, according as each of these phenomena takes place at day-break or twilight. It requires an interval of three quarters of an hour at least before the rising of the sun or after his setting, for the stars to be visible to us. In addition to this, there are certain stars which rise and set twice. All that we here state bears reference, it must be remembered, to the fixed stars only.

Detailed table of contents

CHAP. 59.

THE EPOCHS OF THE SEASONS.

The year is divided into four periods or seasons, the recurrence of which is indicated by the increase or diminution of the daylight. Immediately after the winter solstice the days begin to increase, and by the time of the vernal equinox, or in other words, in ninety days and three hours, the day is equal in length to the night. After this, for ninety-four days and twelve hours, the days continue to increase, and the nights to diminish in proportion, up to the summer solstice; and from that point the days, though gradually decreasing, are still in excess of the nights for ninety-two days, twelve hours, until the autumnal equinox. At this period the days are of equal length with the nights, and after it they continue to decrease inversely to the nights until the winter solstice, a period of eighty-eight days and three hours. In all these calculations, it must be remembered, equinoctial hours are spoken of, and not those measured arbitrarily in reference to the length of any one day in particular. All these seasons, too, commence at the eighth degree of the signs of the Zodiac. The winter solstice begins at the eighth degree of Capricorn, the eighth day before the calends of January, in general; the vernal equinox at the eighth degree of Aries; the summer solstice, at the eighth degree of Cancer; and the autumnal equinox at the eighth degree of Libra: and it is rarely that these days do not respectively give some indication of a change in the weather.

These four seasons again, are subdivided, each of them, into two equal parts. Thus, for instance, between the summer solstice and the autumnal equinox, the setting of the Lyre, on the forty-sixth day, indicates the beginning of autumn; between the autumnal equinox and the winter solstice, the morning setting of the Vergiliæ, on the forty-fourth day, denotes the beginning of winter; between the winter solstice and the vernal equinox, the prevalence of the west winds on the forty-fifth day, denotes the commencement of spring; and between the vernal equinox and the summer solstice, the morning rising of the Vergiliæ, on the forty-eighth day, announces the commencement of summer. We shall here make seed-time, or in other words, the morning setting of the Vergiliæ, our starting-point; and shall not interrupt the thread of our explanation by making any mention of the minor constellations, as such a course would only augment the difficulties that already exist. It is much about this period that the stormy constellation of Orion departs, after traversing a large portion of the heavens.

CHAP. 60.

THE PROPER TIME FOR WINTER SOWING.

Most persons anticipate the proper time for sowing, and begin to put in the corn immediately after the eleventh day of the autumnal equinox, at the rising of the Crown, when we may reckon, almost to a certainty, upon several days of rainy weather in succession. Xenophon is of opinion, that sowing should not be commenced until the Deity has given us the signal for it, a term by which Cicero understands the rains that prevail in November. The true method to be adopted, however, is not to sow until the leaves begin to fall. Some persons are of opinion that this takes place at the setting of the Vergiliæ, or the third day before the ides of November, as already stated, and they carefully observe it, for it is a constellation very easily remarked in the heavens, and warns us to resume our winter clothes. Hence it is, that immediately on its setting, the approach of winter is expected, and care is taken by those who are on their guard against the exorbitant charges of the shop-keepers, to provide themselves with an appropriate dress. If the Vergiliæ set with cloudy weather, it forebodes a rainy winter, and the prices of cloaks immediately rise; but if, on the other hand, the weather is clear at that period, a sharp winter is to be expected, and then the price of garments of other descriptions is sure to go up. But as to the husbandman, unacquainted as he is with the phænomena of the heavens, his brambles are to him in place of constellations, and if he looks at the ground he sees it covered with their leaves. This fall of the leaves, earlier in one place and later in another, is a sure criterion of the temperature of the weather; for there is a great affinity between the effects produced by the weather in this respect, and the nature of the soil and climate. There is this peculiar advantage, too, in the careful observation of these effects, that they are sure to be perceptible throughout the whole earth, while at the same time they have certain features which are peculiar to each individual locality. — A person may perhaps be surprised at this, who does not bear in mind that the herb pennyroyal, which is hung up in our larders, always blossoms on the day of the winter solstice; so firmly resolved is Nature that nothing shall remain concealed from us, and in that spirit has given us the fall of the leaf as the signal for sowing.

Such is the true method of interpreting all these phenomena, granted to us by Nature as a manifestation of her will. It is in this way that she warns us to prepare the ground, makes us a promise of a manure, as it were, in the fall of the leaves, announces to us that the earth and the productions thereof are thus protected by her against the cold, and warns us to hasten the operations of agriculture.

CHAP. 61.

WHEN TO SOW THE LEGUMINOUS PLANTS AND THE POPPY.

Varro has given no other sign but this for our guidance in sowing the bean. Some persons are of opinion that it should be sown at full moon, the lentil between the twenty-fifth and thirtieth day of the moon, and the vetch on the same days of the moon; and they assure us that if this is done they will be exempt from the attacks of slugs. Some say, however, that if wanted for fodder, they may be sown at these periods, but if for seed, in the spring. There is another sign, more evident still, supplied us by the marvellous foresight of Nature, with reference to which we will give the words employed by Cicero himself:

“The lentisk, ever green and ever bent
Beneath its fruits, affords a threefold crop:
Thrice teeming, thrice it warns us when to plough.”

One of the periods here alluded to, is the same that is now under consideration, being the appropriate time also for sowing flax and the poppy. With reference to this last, Cato gives the following advice: “Burn, upon land where corn has been grown, the twigs and branches which are of no use to you, and when that is done, sow the poppy there.” The wild poppy, which is of an utility that is quite marvellous, is boiled in honey as a remedy for diseases in the throat, while the cultivated kind is a powerful narcotic. Thus much in reference to winter sowing.

Detailed table of contents

CHAP. 62.

WORK TO BE DONE IN THE COUNTRY IN EACH MONTH RESPECTIVELY.

And now, in order to complete what we may call in some measure an abridgment of the operations of agriculture, it is as well to add that it will be a good plan at the same period to manure the roots of trees, and to mould up the vines — a single hand being sufficient for one jugerum. Where, too, the nature of the locality will allow it, the vines, and the trees upon which they are trained, should be lopped, and the soil turned up with the mattock for seed plots; trenches, too, should be opened out, and the water drained from off the fields, and the presses should be well washed and put away. Never put eggs beneath the hen between the calends of November and the winter solstice: during all the summer and up to the calends of November, you may put thirteen under the hen; but the number must be smaller in winter, not less than nine, however. Democritus is of opinion, that the winter will turn out of the same character as the weather on the day of the winter solstice and the three succeeding days; the same too with the summer and the weather at the summer solstice. About the winter solstice, for about twice seven days mostly, while the halcyon is sitting, the winds are lulled, and the weather serene; but in this case, as in all others, the influence of the stars must only be judged of by the result, and we must not expect the changes of the weather, as if out upon their recognizances, to make their appearance exactly on certain predetermined days.

Detailed table of contents

CHAP. 63.

WORK TO BE DONE AT THE WINTER SOLSTICE.

Be careful never to touch the vine at the winter solstice. Hyginus recommends us to strain and even rack-off wine at the seventh day after the winter solstice, provided the moon is seven days old. About this period, also, the cherry-tree, he says, should be planted. Acorns, too, should now be put in soak for the oxen, a modius for each pair. If given in larger quantities, this food will prove injurious to their health; and whenever it is given, if they are fed with it for less than thirty days in succession, an attack of scab in the spring, it is said, will be sure to make you repent.

This, too, is the period that we have already assigned for cutting timber — other kinds of work, again, may be found for the hours of the night, which are then so greatly prolonged. There are baskets, hurdles, and panniers to be woven, and wood to be cut for torches: squared stays for the vine may be prepared, too, thirty in the day time, and if rounded, as many as sixty. In the long hours of the evening, too, some five squared stays, or ten rounded ones may be got ready, and the same number while the day is breaking.

CHAP. 64.

WORK TO BE DONE BETWEEN THE WINTER SOLSTICE AND THE PREVALENCE OF THE WEST WINDS.

Between the winter solstice and the period when the west winds begin to prevail, the following, according to Cæsar, are the more important signs afforded by the constellations: the Dog sets in the morning, upon the third day before the calends of January; a day on the evening of which the Eagle sets to the people of Attica and the adjoining countries. On the day before the nones of January, according to Cæsar's computation, the Dolphin rises in the morning, and on the next day, the Lyre, upon the evening of which the Arrow sets to the people of Egypt. Upon the sixth day before the ides of January, the Dolphin sets in the evening, and Italy has many days of continuous cold; the same is the case also when the sun enters Aquarius, about the sixteenth day before the calends of February. On the eighth before the calends of February, the star which Tubero calls the Royal Star sets in the morning in the breast of Leo, and in the evening of the day before the nones of February, the Lyre sets.

During the latter days of this period, whenever the nature of the weather will allow of it, the ground should be turned up with a double mattock, for planting the rose and the vine — sixty men to a jugerum. Ditches, too, should be cleaned out, or new ones made; and the time of day-break may be usefully employed in sharpening iron tools, fitting on handles, repairing such dolia as may have been broken, and rubbing up and cleaning their staves.

CHAP. 65.

WORK TO BE DONE BETWEEN THE PREVALENCE OF THE WEST WINDS AND THE VERNAL EQUINOX.

Between the prevalence of the west winds and the vernal equinox, the fourteenth day before the calends of March, according to Cæsar, announces three days of changeable weather; the same is the case, too, with the eighth before the calends of March, at the first appearance of the swallow, Arcturus rising on the evening of the next day. Cæsar has observed, that the same takes place on the third before the nones of March, at the rising of Cancer; and most authorities say the same with reference to the emersion of the Vintager. On the eighth before the ides of March, the northern limb of Pisces rises, and on the next day Orion, at which period also, in Attica, the Kite is first seen. Cæsar has noted, too, the setting of Scorpio on the ides of March, a day that was so fatal to him; and on the fifteenth before the calends of April, the Kite appears in Italy. On the twelfth before the calends of April, the Horse sets in the morning.

This interval of time is a period of extreme activity for the agriculturist, and affords him a great number of occupations, in reference to which, however, he is extremely liable to be deceived. He is summoned to the commencement of these labours, not upon the day on which the west winds ought to begin, but upon the day on which they really do begin, to blow. This moment then must be looked for with the most careful attention, as it is a signal which the Deity has vouchsafed us in this month, attended with no doubts or equivocations, if only looked for with scrupulous care. We have already stated in the Second Book, the quarter in which this wind blows, and the exact point from which it comes, and before long we shall have occasion to speak of it again still more in detail.

In the mean time, however, setting out from the day, whatever it may happen to be, on which the west winds begin to prevail (for it is not always on the seventh before the ides of February that they do begin), whether, in fact, they begin to blow before the usual time, as is the case with an early spring, or whether after, which generally happens when the winter is prolonged — there are subjects innumerable to engage the attention of the agriculturist, and those, of course, should be the first attended to, which will admit of no delay. Three month wheat must now be sown, the vine pruned in the way we have already described, the olive carefully attended to, fruit-trees put in and grafted, vineyards cleaned and hoed, seedlings laid out, and replaced in the nursery by others, the reed, the willow, and the broom planted and lopped, and the elm, the poplar, and the plane planted in manner already mentioned. At this period, also, the crops of corn ought to be weeded, and the winter kinds, spelt more particularly, well hoed. In doing this, there is a certain rule to be observed, the proper moment being when four blades have made their

appearance, and with the bean this should never be done until three leaves have appeared above ground; even then, however, it is a better plan to clean them only with a slight hoeing, in preference to digging up the ground — but in no case should they ever be touched the first fifteen days of their blossom. Barley must never be hoed except when it is quite dry: take care, too, to have all the pruning done by the vernal equinox. Four men will be sufficient for pruning a jugerum of vineyard, and each hand will be able to train fifteen vines to their trees.

At this period, too, attention should be paid to the gardens and rose-beds, subjects which will be separately treated of in succeeding Books; due care should be given to ornamental gardening as well. It is now, too, the very best time for making ditches. The ground should now be opened for future purposes, as we find recommended by Virgil in particular, in order that the sun may thoroughly warm the clods. It is a piece of even more sound advice, which recommends us to plough no lands in the middle of spring but those of middling quality; for if this is done with a rich soil, weeds will be sure to spring up in the furrows immediately; and if, on the other hand, it is a thin, meagre land, as soon as the heat comes on, it will be dried up, and so lose all the moisture which should be reserved to nourish the seed when sown. It is a much better plan, beyond a doubt, to plough such soils as these in autumn.

Cato lays down the following rules for the operations of spring. “Ditches,” he says, “should be dug in the seed-plots, vines should be grafted, and the elm, the fig, the olive, and other fruit-trees planted in dense and humid soils. Such meadows as are not irrigated, must be manured in a dry moon, protected from the western blasts, and carefully cleaned; noxious weeds must be rooted up, fig-trees cleared, new seed-plots made, and the old ones dressed: all this should be done before you begin to hoe the vineyard. When the pear is in blossom, too, you should begin to plough, where it is a meagre, gravelly soil. When you have done all this, you may plough the more heavy, watery soils, doing this the last of all.”

The proper time for ploughing, then, is denoted by these two signs, the earliest fruit of the lentisk making its appearance, and the blossoming of the pear. There is a third sign, however, as well, the flowering of the squill among the bulbous, and of the narcissus among the garland, plants. For both the squill and the narcissus, as well as the lentisk, flower three times, denoting by their first flowering the first period for ploughing, by the second flowering the second, and by the third flowering the last; in this way it is that one thing affords hints for another. There is one precaution, too, that is by no means the least important among them all, not to let ivy touch the bean while in blossom; for at this period the ivy is noxious to it, and most baneful in its effects. Some plants, again, afford certain signs which bear reference more particularly to themselves, the fig for instance; when a few leaves only are found shooting from the summit, like a cup in shape, then it is more particularly that the fig-tree should be planted.

Detailed table of contents

CHAP. 66.

WORK TO BE DONE AFTER THE VERNAL EQUINOX.

The vernal equinox appears to end on the eighth day before the calends of April. Between the equinox and the morning rising of the Vergiliæ, the calends of April announce, according to Cæsar, [stormy weather]. Upon the third before the nones of April, the Vergiliæ set in the evening in Attica, and the day after in Bœotia, but according to Cæsar and the Chaldæans, upon the nones. In Egypt, at this time, Orion and his Sword begin to set. According to Cæsar, the setting of Libra on the sixth before the ides of April announces rain. On the fourteenth before the calends of May, the Suciæ set to the people of Egypt in the evening, a stormy constellation, and significant of tempests both by land and sea. This constellation sets on the sixteenth in Attica, and on the fifteenth, according to Cæsar, announcing four days of bad weather in succession: in Assyria it sets upon the twelfth before the calends of May. This constellation has ordinarily the name of Parilicium, from the circumstance that the eleventh before the calends of May is observed as the natal day of the City of Rome; upon this day, too, fine weather generally returns, and gives us a clear sky for our observations. The Greeks call the Suciæ by the name of "Hyades," in consequence of the rain and clouds which they bring with them; while our people, misled by the resemblance of the Greek name to another word of theirs, meaning a "pig," have imagined that the constellation receives its name from that word, and have consequently given it, in their ignorance, the name of "Suciæ," or the "Little Pigs."

In the calculations made by Cæsar, the eighth before the calends of May is a day remarked, and on the seventh before the calends, the constellation of the Kids rises in Egypt. On the sixth before the calends, the Dog sets in the evening in Bœotia and Attica, and the Lyre rises in the morning. On the fifth before the calends of May, Orion has wholly set to the people of Assyria, and on the fourth before the calends the Dog. On the sixth before the nones of May, the Suciæ rise in the morning, according to the calculation of Cæsar, and on the eighth before the ides, the She-goat, which announces rain. In Egypt the Dog sets in the evening of the same day. Such are pretty nearly the movements of the constellations up to the sixth before the ides of May, the period of the rising of the Vergiliæ.

In this interval of time, during the first fifteen days, the agriculturist must make haste and do all the work for which he has not been able to find time before the vernal equinox; and he should bear in mind that those who are late in pruning their vines are exposed to jibes and taunts, in imitation of the note of the bird of passage known to us as the cuckoo. For it is looked upon as a disgrace, and one that subjects him to well-merited censure, for that bird, upon its arrival, to find him only then pruning his vines. Hence it is, too, that

we find those cutting jokes, of which our peasantry are the object, at the beginning of spring. Still, however, all such jokes are to be looked upon as most abominable, from the ill omens they convey.

In this way, then, we see that, in agricultural operations, the most trifling things are construed as so many hints supplied us by Nature. The latter part of this period is the proper time for sowing panic and millet; the precise moment, however, is just after the barley has ripened. In the case of the very same land, too, there is one sign that points in common both to the ripening of the barley and the sowing of panic and millet — the appearance of the glow-worm, shining in the fields at night. “Cicindelæ” is the name given by the country people to these flying stars, while the Greeks call them “lampyrides,” — another manifestation of the incredible bounteousness of Nature.

Detailed table of contents

CHAP. 67. (27.)

WORK TO BE DONE AFTER THE RISING OF THE VERGILIÆ: HAY-MAKING.

Nature had already formed the Vergiliæ, a noble group of stars, in the heavens; but not content with these, she has made others as well for the face of the earth, crying aloud, as it were “Why contemplate the heavens, husbandman? Why, rustic, look up at the stars? Do not the nights already afford you a sleep too brief for your fatigues? Behold now! I scatter stars amid the grass for your service, and I reveal them to you in the evening, as you return from your work; and that you may not disregard them, I call your attention to this marvel. Do you not see how the wings of this insect cover a body bright and shining like fire, and how that body gives out light in the hours of the night even? I have given you plants to point out to you the hours, and, that you may not have to turn your eyes from the earth, even to view the sun, the heliotropium and the lupine have been made by me to move with his movements. Why then still look upwards, and scan the face of heaven? Behold, here before your very feet are your Vergiliæ; upon a certain day do they make their appearance, and for a certain time do they stay. Equally certain, too, it is that of that constellation they are the offspring. Whoever, then, shall put in his summer seeds before they have made their appearance, will infallibly find himself in the wrong.”

It is in this interval, too, that the little bee comes forth, and announces that the bean is about to blossom; for it is the bean in flower that summons it forth. We will here give another sign, which tells us when the cold is gone; as soon as ever you see the mulberry in bud, you have no occasion to fear any injury from the rigour of the weather.

It is the time, now, to put in cuttings of the olive, to clear away between the olive-trees, and, in the earlier days of the equinox, to irrigate the meadows. As soon, however, as the grass puts forth a stem, you must shut off the water from the fields. You must now lop the leafy branches of the vine, it being the rule that this should be done as soon as the branches have attained four fingers in length; one labourer will be sufficient for a jugerun. The crops of corn, too, should be hoed over again, an operation which lasts twenty days. It is generally thought, however, that it is injurious to both vine and corn to begin hoeing directly after the equinox. This is the proper time, too, for washing sheep.

After the rising of the Vergiliæ the more remarkable signs are, according to Cæsar, the morning rising of Arcturus, which takes place on the following day; and the rising of the Lyre on the third before the ides of May. The She-goat sets in the evening of the twelfth before the calends of June, and in Attica the Dog. On the eleventh before the calends of June, according to Cæsar, Orion's Sword begins to appear; and, according to the same writer, on the

fourth before the nones of June the Eagle rises in the evening, and in Assyria as well. On the seventh before the ides of June Arcturus sets in the morning to the people of Italy, and on the fourth before the ides the Dolphin rises in the evening. On the seventeenth before the calends of July Orion's Sword rises in Italy, and, four days later, in Egypt. On the eleventh before the calends of July, according to Cæsar's reckoning, Orion's Sword begins to set; and the eighth before the calends of July, the longest day in the year, with the shortest night, brings us to the summer solstice.

In this interval of time the vine should be cleared of its superfluous branches, and care taken to give an old vine one turning up at the roots, a young tree two. Sheep, too, are sheared at this period, lupines turned up for manuring the land, the ground dug, vetches cut for fodder, and beans gathered in and threshed.

(28.) About the calends of June the meadows are mown; the cultivation of which, the one which is the easiest of all, and requires the smallest outlay, leads me to enter into some further details relative to it. Meadow lands should be selected in a rich, or else a moist or well-watered, soil, and care should be taken to drain the rain-water upon them from the high- road. The best method of ensuring a good crop of grass, is first to plough the land, and then to harrow it: but, before passing the harrow over it, the ground should be sprinkled with such seed as may have fallen from the hay in the haylofts and mangers. The land should not be watered, however, the first year, nor should cattle be put to graze upon it before the second hay-harvest, for fear lest the blade should be torn up by the roots, or be trodden down and stunted in its growth. Meadow land will grow old in time, and it requires to be renovated every now and then, by sowing upon it a crop of beans, or else rape or millet, after which it should be sown the next year with corn, and then left for hay the third. Care, too, should be taken, every time the grass is cut, to pass the sickle over the ground, and so cut the aftermath which the mowers have left behind; for it is a very bad plan to leave any of the grass and let it shed its seed there. The best crop for meadow land is trefoil, and the next best is grass; nummulus is the very worst of all, as it bears a pod which is particularly injurious; equisætis, too, which derives its name from its resemblance to horse-hair, is of a noxious character. The proper time for mowing grass is when the ear begins to shed its blossom and to grow strong: care must be taken to cut it before it becomes dry and parched. "Don't mow your hay too late," says Cato; "but cut it before the seed is ripe." Some persons turn the water upon it the day before mowing, where it is practicable to do so. It is the best plan to cut hay in the night while the dews are falling. In some parts of Italy the mowing is not done till after harvest.

This operation, too, was a very expensive one in ancient times. In those days the only whetstones known were those of Crete and other places beyond sea, and they only used oil to sharpen the scythe with. For this purpose the mower moved along, with a horn, to hold the oil, fastened to his thigh. Italy

has since furnished us with whetstones which are used with water, and give an edge to the iron quite equal to that imparted by the file; these water-whetstones, however, turn green very quickly. Of the scythe there are two varieties; the Italian, which is considerably shorter than the other, and can be handled among underwood even; and the Gallic, which makes quicker work of it, when employed on extensive domains, for there they cut the grass in the middle only, and pass over the shorter blades. The Italian mowers cut with one hand only. It is a fair day's work for one man to cut a jugerum of grass, and for another to bind twelve hundred sheaves of four pounds each. When the grass is cut it should be turned towards the sun, and must never be stacked until it is quite dry. If this last precaution is not carefully taken, a kind of vapour will be seen arising from the rick in the morning, and as soon as the sun is up it will ignite to a certainty, and so be consumed. When the grass has been cut, the meadow must be irrigated again, for the purpose of ensuring a crop in the autumn, known to us as the "cordum," or aftermath. At Interamna in Umbria the grass is cut four times a-year, and this although the meadows there are not irrigated, — in most places, three. After all this has been done, too, the pasturage of the land is found no less lucrative than the hay it has produced. This, however, is a matter of consideration for those more particularly who rear large herds of cattle, and every one whose occupation it is to breed beasts of burden, will have his own opinions upon the subject: it is found, however, the most lucrative of all by those whose business it is to train chariot-horses.

Detailed table of contents

CHAP. 68.

THE SUMMER SOLSTICE.

We have already stated that the summer solstice arrives at the eighth degree of Cancer, and upon the eighth day before the calends of July: this is an important crisis in the year, and of great interest to the whole earth. Up to this period from the time of the winter solstice the days have gone on increasing, and the sun has continued for six months making his ascension towards the north; having now surmounted the heights of the heavens, at this point he reaches the goal, and after doing so, commences his return towards the south; the consequence of which is, that for the next six months he increases the nights and subtracts from the length of the days. From this period, then, it is the proper time to gather in and store away the various crops in succession, and so make all due preparations for the rigour and severity of the winter.

It was only to be expected that Nature should point out to us the moment of this change by certain signs of an indubitable character; and she has accordingly placed them beneath the very hands of the agriculturist, bidding the leaves turn round upon that day, and so denote that the luminary has now run its course. And it is not the leaves of trees only that are wild and far remote that do this, nor have those persons who are on the look-out for these signs to go into devious forests and mountain tracts to seek them. Nor yet, on the other hand, are they to be seen in the leaves of trees only that are grown in the vicinity of cities or reared by the hand of the ornamental gardener, although in them they are to be seen as well. Nature upon this occasion turns the leaf of the olive which meets us at every step; she turns the leaf of the linden, sought by us, as it is, for a thousand purposes; she turns the leaf of the white poplar, too, wedded to the vine that grows upon its trunk. And still, for her, all this is not enough. "You have the elm," she says, "reared for the support of the vine, and the leaf of that I will make to turn as well. The leaves of this tree you have to gather for fodder, the leaves of the vine you prune away. Only look upon them, and there you behold the solstice; they are now pointing towards a quarter of the heavens the reverse of that towards which they looked the day before. The twigs of the withy, that most lowly of trees, you employ for tying things without number. You are a head taller than it — I will make its leaves to turn round as well. Why complain, then, that you are but a rustic peasant? It shall be no fault of mine if you do not understand the heavens and become acquainted with the movements of the celestial bodies. I will give another sign, too, that shall address itself to your ear — only listen for the cooing of the ring-doves; and beware of supposing that the summer solstice is past, until you see the wood-pigeon sitting on her eggs."

Between the summer solstice and the setting of the Lyre, on the sixth day before the calends of July, according to Cæsar's reckoning, Orion rises, and

upon the fourth before the nones of July, his Belt rises to the people of Assyria. Upon the morning of the same day, also, the scorching constellation of Procyon rises. This last constellation has no name with the Romans, unless, indeed, we would consider it as identical with Canicula, or Lesser Dog, which we find depicted among the stars; this last is productive of excessive heat, as we shall shortly have further occasion to state. On the fourth before the nones of July, the Crown sets in the morning to the people of Chaldæa, and in Attica, the whole of Orion has risen by that day. On the day before the ides of July, the rising of Orion ends to the Egyptians also; on the sixteenth before the calends of August, Procyon rises to the people of Assyria, and, the day but one after, of nearly all other countries as well, indicating a crisis that is universally known among all nations, and which by us is called the rising of the Dog-star; the sun at this period entering the first degree of Leo. The Dog-star rises on the twenty-third day after the summer solstice; the influence of it is felt by both ocean, and earth, and even by many of the animals as well, as stated by us elsewhere on the appropriate occasions. No less veneration, in fact, is paid to this star, than to those that are consecrated to certain gods; it kindles the flames of the sun, and is one great source of the heats of summer.

On the thirteenth day before the calends of August, the Eagle sets in the morning to the people of Egypt, and the breezes that are the precursors of the Etesian winds, begin to blow; these, according to Cæsar, are first perceived in Italy, on the tenth before the calends of August. The Eagle sets in the morning of that day to the people of Attica, and on the third before the calends of August, the Royal Star in the breast of Leo rises in the morning, according to Cæsar. On the eighth before the ides of August, one half of Arcturus has ceased to be visible, and on the third before the ides the Lyre, by its setting, opens the autumn, — according to Cæsar at least; though a more exact calculation has since shown, that this takes place on the sixth day before the ides of that month.

The time that intervenes between these periods is one that is of primary importance in the cultivation of the vine; as the constellation of which we have spoken, under the name of Canicula, has now to decide upon the fate of the grape. It is at this period that the grapes are said to be charred, a blight falling upon them which burns them away, as though red-hot coals had been applied to them. There is no hail that can be compared with this destructive malady, nor yet any of those tempests, which have been productive of such scarcity and dearth. For the evil effects of these, at the very utmost, are only felt in isolated districts, while the coal blight, on the other hand, extends over whole countries, far and wide. Still, however, the remedy would not be very difficult, were it not that men would much rather calumniate Nature, than help themselves. It is said that Democritus, who was the first to comprehend and demonstrate that close affinity which exists between the heavens and the earth, finding his laborious researches upon that subject slighted by the more opulent of his fellow-citizens, and presaging the high price of oil, which was about to

result upon the rising of the Vergiliæ, (as we have already mentioned, and shall have to explain more fully hereafter), bought up all the oil in the country, which was then at a very low figure, from the universal expectation of a fine crop of olives; a proceeding which greatly surprised all who knew that a life of poverty and learned repose was so entirely the object of his aspirations. When, however, his motives had been fully justified by the result, and vast riches had flowed in upon him apace, he returned all his profits to the disappointed proprietors, whose avarice had now taught them to repent, thinking it quite sufficient to have thus proved how easy it was for him to acquire riches whenever he pleased. At a more recent period, again, Sextius, a Roman philosopher residing at Athens, made a similar application of his knowledge. Such, then, is the utility of science, the instruction provided by which it shall be my aim, as clearly and as perspicuously as possible, to apply to the various occupations of a country life.

Most writers have said that it is the dew, scorched by a burning sun, that is the cause of mildew in corn, and of coal-blight in the vine; this, however, seems to me in a great measure incorrect, and it is my opinion that all blights result entirely from cold, and that the sun is productive of no injurious effects whatever. This, in fact, will be quite evident, if only a little attention is paid to the subject; for we find that the blight makes its appearance at first in the night time only, and before the sun has shone with any vigour. The natural inference is, that it depends entirely upon the moon, and more particularly as such a calamity as this is never known to happen except at the moon's conjunction, or else at the full moon, periods at which the influence of that heavenly body is at its greatest height. For at both of these periods, as already stated by us more than once, the moon is in reality at the full; though during her conjunction she throws back to the heavens all the light which she has received from the sun. The difference in the effects produced by the moon at these two periods is very great, though at the same time equally apparent; for at the conjunction, that body is extremely hot in summer, but cold in winter; while, on the other hand, at the full moon, the nights are cold in summer, but warm in winter. The reason of this, although Fabianus and the Greek writers adopt another method of explaining it, is quite evident. During the moon's conjunction in summer, she must of necessity move along with the sun in an orbit nearer to the earth, and so become warmed by the heat which she receives by reason of her closer vicinity to the sun. In winter, again, at the time of the conjunction, she is farther off from us, the sun being also removed to a greater distance. On the other hand, again, when the moon is at the full in summer, she is more remote from the earth, and in opposition with the sun; while, in winter, she approaches nearer to us at that period, by adopting the same orbit as at her conjunction in summer. Naturally humid herself, as often as from her position she is cold, she congeals to an unlimited extent the dews which fall at that period of the year.

CHAP. 69.

CAUSES OF STERILITY.

But we ought always to bear in mind, more particularly, that there are two varieties of evils that are inflicted upon the earth by the heavens. The first of these, known by us under the name of “tempests,” comprehends hail-storms, hurricanes and other calamities of a similar nature; when these take place at the full moon, they come upon us with additional intensity. These tempests take their rise in certain noxious constellations, as already stated by us on several occasions, Arcturus, for instance, Orion, and the Kids.

The other evils that are thus inflicted upon us, supervene with a bright, clear sky, and amid the silence of the night, no one being sensible of them until we have perceived their effects. These dispensations are universal and of a totally different character from those previously mentioned, and have various names given to them, sometimes mildew, sometimes blast, and sometimes coal blight; but in all cases sterility is the infallible result. It is of these last that we have now to speak, entering into details which have not hitherto been treated of by any writer; and first of all we will explain the causes of them.

(29.) Independently of the moon, there are two principal causes of these calamities, which emanate more particularly from two quarters of the heavens of but limited extent. On the one hand, the Vergiliæ exercise an especial influence on our harvests, as it is with their rising that the summer begins, and with their setting, the winter; thus embracing, in the space of six months, the harvest, the vintage, and the ripening of all the vegetable productions. In addition to this, there is a circular tract in the heavens, quite visible to the human eye even, known as the Milky Way. It is the emanations from this, flowing as it were from the breast, that supply their milky nutriment to all branches of the vegetable world. Two constellations more particularly mark this circular tract, the Eargle in the north, and Canicula in the south; of this last, we have already made mention in its appropriate place. This circle traverses also Sagittarius and Gemini, and passing through the centre of the sun, cuts the equinoctial line below, the constellation of the Eagle making its appearance at the point of intersection on the one side, and Canicula on the other. Hence it is that the influences of both these constellations develop themselves upon all cultivated lands; it being at these points only that the centre of the sun is brought to correspond with that of the earth. If, then, at the moments of the rising and the setting of these constellations, the air, soft and pure, transmits these genial and milky emanations to the earth, the crops will thrive and ripen apace; but if on the other hand, the moon, as already mentioned, sheds her chilling dews, the bitterness thereof infuses itself into these milky secretions, and so kills the vegetation in its birth. The measure of

the injury so inflicted on the earth depends, in each climate, upon the combination of the one or other of these causes; and hence it is that it is not felt in equal intensity throughout the whole earth, nor even precisely at the same moment of time. We have already said that the Eagle rises in Italy on the thirteenth day before the calends of January, and the ordinary course of Nature does not permit us before that period to reckon with any degree of certainty upon the fruits of the earth; for if the moon should happen to be in conjunction at that time, it will be a necessary consequence, that all the winter fruits, as well as the early ones, will receive injury more or less.

The life led by the ancients was rude and illiterate; still, as will be readily seen, the observations they made were not less remarkable for ingenuity than are the theories of the present day. With them there were three set periods for gathering in the produce of the earth, and it was in honour of these periods that they instituted the festive days, known as the Robigalia, the Floralia, and the Vinalia. The Robigalia were established by Numa in the fortieth year of his reign, and are still celebrated on the seventh day before the calends of May, as it is at this period that mildew mostly makes its first attacks upon the growing corn. Varro fixes this crisis at the moment at which the sun enters the tenth degree of Taurus, in accordance with the notions that prevailed in his day: but the real cause is the fact, that thirty-one days after the vernal equinox, according to the observations of various nations, the Dog-star sets between the seventh and fourth before the calends of May, a constellation baneful in itself, and to appease which a young dog should first be sacrificed. The same people also, in the year of the City 513, instituted the Floralia, a festival held upon the fourth before the calends of May, in accordance with the oracular injunctions of the Sibyl, to secure a favourable season for the blossoms and flowers. Varro fixes this day as the time at which the sun enters the fourteenth degree of Taurus. If there should happen to be a full moon during the four days at this period, injury to the corn and all the plants that are in blossom, will be the necessary result. The First Vinalia, which in ancient times were established on the ninth before the calends of May, for the purpose of tasting the wines, have no signification whatever in reference to the fruits of the earth, any more than the festivals already mentioned have in reference to the vine and the olive; the germination of these last not commencing, in fact, till the rising of the Vergiliæ, on the Sixth day before the ides of May, as already mentioned on previous occasions. This, again, is another period of four days, which should never be blemished by dews, as the chilling constellation of Arcturus, which sets on the following day, will be sure to nip the vegetation; still less ought there to be a full moon at this period.

On the fourth before the nones of June, the Eagle rises again in the evening, a critical day for the olives and vines in blossom, if there should happen to be a full moon. For my part, I am of opinion that the eighth before the calends of July, the day of the summer solstice, must be a critical day, for a similar reason; and that the rising of the Dog-star, twenty-three days after

the summer solstice, must be so too, in case the moon is then in conjunction; for the excessive heat is productive of injurious effects, and the grape becomes prematurely ripened, shrivelled, and tough. Again, if there is a full moon on the fourth before the nones of July, when Canicula rises to the people of Egypt, or at least on the sixteenth before the calends of August, when it rises in Italy, it is productive of injurious results. The same is the case, too, from the thirteenth day before the calends of August, when the Eagle sets, to the tenth before the calends of that month. The Second Vinalia, which are celebrated on the fourteenth before the calends of September, bear no reference to these influences. Varro fixes them at; the period at which the Lyre begins its morning setting, and says that this indicates the beginning of autumn, the day having been set apart for the purpose of propitiating the weather: at the present day, however, it is observed that the Lyre sets on the sixth before the ides of August.

Within these periods there are exerted the sterilizing influences of the heavens, though I am far from denying that they may be considerably modified by the nature of the locality according as it is cold or hot. Still, however, it is sufficient for me to have demonstrated the theory; the modifications of its results depending, in a great degree, upon attentive observation. It is beyond all question too, that either one of these two causes will be always productive of its own peculiar effects, the full moon, I mean, or else the moon's conjunction. And here it suggests itself how greatly we ought to admire the bounteous provisions made for us by Nature; for, in the first place, these calamitous results cannot by any possibility befall us every year, in consequence of the fixed revolutions of the stars; nor indeed, when they do happen, beyond a few nights in the year, and it may be easily known beforehand which nights those are likely to be. In order, too, that we might not have to apprehend these injuries to vegetation in all the months, Nature has so ordained that the times of the moon's conjunction in summer, and of the full moon in winter, with the exception of two days only at those respective periods, are well ascertained, and that there is no danger to be apprehended on any but the nights of summer, and those nights the shortest of all; in the day-time, on the other hand, there is nothing to fear. And then, besides, these phenomena may be so easily understood, that the ant even, that most diminutive of insects, takes its rest during the moon's conjunction, but toils on, and that during the night as well, when the moon is at the full; the bird, too, called the "parra" disappears upon the day on which Sirius rises, and never reappears until that star has set; while the witwall, on the other hand, makes its appearance on the day of the summer solstice. The moon, however, is productive of no noxious effects at either of these periods, except when the nights are clear, and every movement of the air is lulled; for so long as clouds prevail, or the wind is blowing, the night dews never fall. And then, besides, there are certain remedies to counteract these noxious influences.

CHAP. 70.

REMEDIES AGAINST THESE NOXIOUS INFLUENCES.

When you have reason to fear these influences, make bonfires in the fields and vineyards of cuttings or heaps of chaff, or else of the weeds that have been rooted up; the smoke will act as a good preservative. The smoke, too, of burning chaff will be an effectual protection against the effects of fogs, when likely to be injurious. Some persons recommend that three crabs should be burnt alive among the trees on which the vines are trained, to prevent these from being attacked by coal blight; while others say that the flesh of the silurus should be burnt in a slow fire, in such a way that the smoke may be dispersed by the wind throughout the vineyard.

Varro informs us, that if at the setting of the Lyre, which is the beginning of autumn, a painted grape is consecrated in the midst of the vineyard, the bad weather will not be productive of such disastrous results as it otherwise would. Archibius has stated, in a letter to Antiochus, king of Syria, that if a bramble-frog is buried in a new earthen vessel, in the middle of a corn-field, there will be no storms to cause injury.

CHAP. 71.

WORK TO BE DONE AFTER THE SUMMER SOLSTICE.

The following are the rural occupations for this interval of time-the ground must have another turning up, and the trees must be cleared about the roots and moulded up, where the heat of the locality requires it. Those plants, however, which are in bud must not be spaded at the roots, except where the soil is particularly rich. The seed-plots, too, must be well cleared with the hoe, the barley-harvest got in, and the threshing-floor prepared for the harvest with chalk, as Cato tells us, slackened with amurca of olives; Virgil makes mention of a method still more laborious even. In general, however, it is considered sufficient to make it perfectly level, and then to cover it with a solution of cow-dung and water; this being thought sufficient to prevent the dust from rising.

CHAP. 72. (30.)

THE HARVEST.

The mode of getting in the harvest varies considerably. In the vast domains of the provinces of Gaul a large hollow frame, armed with teeth and supported on two wheels, is driven through the standing corn, the beasts being yoked behind it; the result being, that the ears are torn off and fall within the frame. In other countries the stalks are cut with the sickle in the middle, and the ears are separated by the aid of paddle-forks. In some places, again, the corn is torn up by the roots; and it is asserted by those who adopt this plan, that it is as good as a light turning up for the ground, whereas, in reality, they deprive it of its juices. There are differences in other respects also: in places where they thatch their houses with straw, they keep the longest haulms for that purpose; and where hay is scarce, they employ the straw for litter. The straw of panic is never used for thatching, and that of millet is mostly burnt; barley-straw, however, is always preserved, as being the most agreeable of all as a food for oxen. In the Gallic provinces panic and millet are gathered, ear by ear, with the aid of a comb carried in the hand.

In some places the corn is beaten out by machines upon the threshing-floor, in others by the feet of mares, and in others with flails. The later wheat is cut, the more prolific it is; but it is got in early, the grain is finer and stronger. The best rule is to cut it before the grain hardens, and just as it is changing colour: though the oracles on husbandry say that it is better to begin the harvest two days too soon than two days too late. Winter and other wheat must be treated exactly the same way both on the threshing-floor and in the granary. Spelt, as it is difficult to be threshed, should be stored with the chaff on, being only disengaged of the straw and the beard.

Many countries make use of chaff for hay: the smoother and thinner it is, and the more nearly resembling dust, the better; hence it is that the chaff of millet is considered the best, that of barley being the next best, and that of wheat the worst of all, except for beasts that are hard worked. In stony places they break the haulms, when dry, with staves, for the cattle to lie upon: if there is a deficiency of chaff, the straw as well is ground for food. The following is the method employed in preparing it: it is cut early and sprinkled with bay salt, after which it is dried and rolled up in trusses, and given to the oxen as wanted, instead of hay. Some persons set fire to the stubble in the fields, a plan that has been greatly extolled by Virgil: the chief merit of it is that the seed of the weeds is effectually destroyed. The diversity of the methods employed in harvesting mainly depends upon the extent of the crops and the price of labour.

CHAP. 73

THE METHODS OF STORING CORN.

Connected with this branch of our subject is the method of storing corn. Some persons recommend that granaries should be built for the purpose at considerable expense, the walls being made of brick, and not less than three feet thick; the corn, they say, should be let in from above, the air being carefully excluded, and no windows allowed. Others, again, say that the granary should have an aspect in no direction but the north-east or north, and that the walls should be built without lime, that substance being extremely injurious to corn; as to what we find recommended in reference to amurca of olives, we have already mentioned it on a former occasion. In some places they build their granaries of wood, and upon pillars, thinking it the best plan to leave access for the air on every side, and from below even. Some persons think, however, that the grain diminishes in bulk if laid on a floor above the level of the ground, and that it is liable to ferment beneath a roof of tiles. Many persons say, too, that the grain should never be stirred up to air it, as the weevil is never known to penetrate beyond four fingers in depth; consequently, beyond that depth there is no danger. According to Columella, the west wind is beneficial to grain, a thing that surprises me, as that wind is generally a very parching one. Some persons recommend that, before housing the corn, a bramble-frog should be hung up by one of the hind legs at the threshold of the granary. To me it appears that the most important precaution of all is to house the grain at the proper time; for if it is unripe when cut, and not sufficiently firm, or if it is got in a heated state, it follows of necessity that noxious insects will breed in it.

There are several causes which contribute to the preservation of grain; the outer coats in some kinds are more numerous, as in millet, for instance; the juices are of an oleaginous nature, and so supply ample moisture, as in sesame, for example; while in other kinds, again, they are naturally bitter, as in the lupine and the chicheling vetch. It is in wheat more particularly that insects breed, as it is apt to heat from the density of its juices, and the grain is covered with a thick bran. In barley the chaff is thinner, and the same is the case with all the leguminous seeds: it is for this reason that they do not ordinarily breed insects. The bean, however, is covered with a coat of a thicker substance: and hence it is that it ferments. Some persons sprinkle wheat, in order to make it keep the longer, with amurea of olives, a quadrantal to a thousand modii: others, again, with powdered Chalcidian or Carian chalk, or with worm-wood. There is a certain earth found at Olynthus, and at Cerinthus, in Eubœa, which prevents grain from spoiling. If garnered in the ear, grain is hardly ever found to suffer any injury.

The best plan, however, of preserving grain, is to lay it up in trenches, called

“siri,” as they do in Cappadocia, Thracia, Spain, and at * * * in Africa. Particular care is taken to dig these trenches in a dry soil, and a layer of chaff is then placed at the bottom the grain, too, is always stored in the ear. In this case, if no air is allowed to penetrate to the corn, we may rest assured that no noxious insects will ever breed in it. Varro says, that wheat, if thus stored, will keep as long as fifty years, and millet a hundred; and he assures us that beans and other leguminous grain, if put away in oil jars with a covering of ashes, will keep for a great length of time. He makes a statement, also, to the effect that some beans were preserved in a cavern in Ambracia from the time of King Pyrrhus until the Piratical War of Pompeius Magnus, a period of about two hundred and twenty years.

The chick-pea is the only grain in which no insect will breed while in the granary. Some persons place upon the heaps of the leguminous grains pitchers full of vinegar and coated with pitch, a stratum of ashes being laid beneath; and they fancy that if this is done, no injury will happen. Some, again, store them in vessels which have held salted provisions, with a coating of plaster on the top, while other persons are in the habit of sprinkling lentils with vinegar scented with laser, and, when dry, giving them a covering of oil. But the most effectual method of all is to get in everything that you would preserve from injury at the time of the moon’s conjunction; and hence it is of the greatest importance to know, when getting in the harvest, whether it is for garnering or whether for immediate sale. If cut during the increase of the moon, grain will increase in size.

CHAP. 74. (31.)

THE VINTAGE, AND THE WORKS OF AUTUMN.

In accordance with the ordinary divisions of the year, we now come to autumn, a period which extends from the setting of the Lyre to the autumnal equinox, and from that to the setting of the Vergiliæ and the beginning of winter. In these intervals, the more important periods are marked by the rising of the Horse to the people of Attica, in the evening of the day before the ides of August; upon which day also the Dolphin sets in Egypt, and, according to Cæsar, in Italy. On the eleventh before the calends of September, the star called the Vintager begins to rise in the morning, according to Cæsar's reckoning, and to the people of Assyria; it announces the ripening of the vintage, a sure sign of which is the change of colour in the grape. On the fifth before the calends of September, the Arrow sets in Assyria, and the Etesian winds cease to blow: on the nones of September, the Vintager rises in Egypt, and in the morning of that day, Arcturus rises to the people of Attica: on the same morning, too, the Arrow sets. On the fifth before the ides of September, according to Cæsar, the She-Goat rises in the evening; and one half of Arcturus becomes visible on the day before the ides of September, being portentous of boisterous weather for five days, both by land and sea.

The theory relative to the effects produced by Arcturus, is stated in the following terms: if showers prevail, it is said, at the setting of the Dolphin, they will not cease so long as Arcturus is visible. The departure of the swallows may be looked upon as the sign of the rising of Arcturus; for if overtaken by it, they are sure to perish.

On the sixteenth day before the calends of October, the Ear of Corn, which Virgo holds, rises to the people of Egypt in the morning, and by this day the Etesian winds have quite ceased to blow. According to Cæsar, this constellation rises on the fourteenth before the calends, and it affords its prognostics to the Assyrians on the thirteenth. On the eleventh before the calends of October, the point of junction in Pisces disappears, and upon the eighth is the autumnal equinox. It is a remarkable fact, and rarely the case, that Philippus, Callippus, Dositheus, Parmeniscus, Conon, Criton, Democritus, and Eudoxus, all agree that the She-Goat rises in the morning of the fourth before the calends of October, and on the third the Kids. On the sixth day before the nones of October, the Crown rises in the morning to the people of Attica, and upon the morning of the fifth, the Charioteer sets. On the fourth before the nones of October, the Crown, according to Cæsar's reckoning, begins to rise, and on the evening of the day after is the setting of the constellation of the Kids. On the eighth before the ides of October, according to Cæsar, the bright star rises that shines in the Crown, and on the evening of the sixth before the ides the Vergiliæ, rise. Upon the ides of

October, the Crown has wholly risen. On the seventeenth before the calends of November, the *Suculæ* rise in the evening, and on the day before the calends, according to Cæsar's reckoning, *Arcturus* sets, and the *Suculæ* rise with the sun. In the evening of the fourth day before the nones of November, *Arcturus* sets. On the fifth before the ides of November, *Orion's* Sword begins to set; and on the third before the ides the *Vergiliæ* set.

In this interval of time, the rural operations consist in sowing rape and turnips, upon the days which have been mentioned on a previous occasion. The people in the country are of opinion, that it is not a good plan to sow rape after the departure of the stork; but for my own part, I am of opinion that it should be sown after the *Vulcanalia*, and the early kind at the same time as panic. After the setting of the *Lyre*, vetches should be sown, kidney-beans and hay-grass: it is generally recommended that this should be done while the moon is in conjunction. This, too, is the proper time for gathering in the leaves: it is fair work for one woodman, to fill four baskets in the day. If the leaves are gathered while the moon is on the wane, they will not decay; they ought not to be dry, however, when gathered.

The ancients were of opinion, that the vintage is never ripe before the equinox; but at the present day I find that it is gathered in before that period; it will be as well, therefore, to give the signs and indications by which the proper moment may be exactly ascertained. The rules for getting in the vintage are to the following effect: Never gather the grape in a heated state, or in other words, when the weather is dry, and before the rains have fallen; nor ought it to be gathered when covered with dew, — or in other words, when dews have fallen during the night, — nor yet before the dews have been dispelled by the sun. Commence the vintage when the bearing-shoots begin to recline upon the stem, or when, after a grape is removed from the bunch, the space left empty is not filled up; this being a sure proof that the berry has ceased to increase in size. It is of the greatest consequence to the grape, that it should be gathered while the moon is on the increase. Each pressing should fill twenty culei, that being the fair proportion. To fill twenty culei and vats from twenty jugera of vineyard, a single press will be enough. In pressing the grape, some persons use a single press-board, but it is a better plan to employ two, however large the single ones may be. It is the length of them that is of the greatest consequence, and not the thickness: if wide, however, they press the fruit all the better. The ancients used to screw down the press-boards with ropes and leather thongs, worked by levers. Within the last hundred years the Greek press has been invented, with thick spiral grooves running down the stem. To this stem there are spokes attached, which project like the rays of a star, and by means of which the stem is made to lift a box filled with stones — a method that is very highly approved of. It is only within the last two-and-twenty years, that a plan has been discovered of employing smaller press-boards, and a less unwieldy press: to effect this, the height has been reduced, and the stem of the screw placed in the middle, the whole pressure being

concentrated upon broad planks placed over the grapes, which are covered also with heavy weights above.

This is the proper time for gathering fruit; the best moment for doing so is when it has begun to fall through ripeness, and not from the effects of the weather. This is the season, too, for extracting the lees of wine, and for boiling defrutum: this last must be done on a night when there is no moon, or if it is a full moon, in the day-time. At other times of the year, it must be done either before the moon has risen, or after it has set. The grapes employed for this purpose should never be gathered from a young vine, nor yet from a tree that is grown in a marshy spot, nor should any grapes be used but those that are perfectly ripe: the liquor, too, should never be skimmed with anything but a leaf; for if the vessel should happen to be touched with wood, the liquor, it is generally thought, will have a burnt and smoky flavour.

The proper time for the vintage is between the equinox and the setting of the Vergiliæ, a period of forty-four days. It is a saying among the growers, that to pitch wine-vessels after that day, in consequence of the coldness of the weather, is only so much time lost. Still, however, I have seen, before now, persons getting in the vintage on the calends of January even, in consequence of the want of wine-vessels, and putting the must into receivers, or else pouring the old wine out of its vessels, to make room for new liquor of a very doubtful quality. This, however, happens not so often in consequence of an over-abundant crop, as through carelessness, or else the avarice which leads people to wait for a rise in prices. The method that is adopted by the most economical managers, is to use the produce supplied by each year, and this, too, is found in the end the most lucrative mode of proceeding. As for the other details relative to wines, they have been discussed at sufficient length already; and it has been stated on a previous occasion, that as soon as the vintage is got in, the olives should at once be gathered, with other particulars relative to the olive after the setting of the Vergiliæ.

Detailed table of contents

CHAP. 75. (32.)

THE REVOLUTIONS OF THE MOON.

I shall now proceed to add some necessary information relative to the moon, the winds, and certain signs and prognostics, in order that I may complete the observations I have to make with reference to the sidereal system. Virgil has even gone so far, in imitation of Democritus, as to assign certain operations to certain days of the moon; but my sole object shall be, as, indeed, it has been throughout this work, to consult that utility which is based upon a knowledge and appreciation of general principles.

All vegetable productions are cut, gathered, and housed to more advantage while the moon is on the wane than while it is on the increase. Manure must never be touched except when the moon is on the wane; and land must be manured more particularly while the moon is in conjunction, or else at the first quarter. Take care to geld your boars, bulls, rams, and kids, while the moon is on the wane. Put eggs under the hen at a new moon. Make your ditches in the night-time, when the moon is at full. Cover up the roots of trees, while the moon is at full. Where the soil is humid, put in seed at the moon's conjunction, and during the four days about that period. It is generally recommended, too, to give an airing to corn and the leguminous grains, and to garner them, towards the end of the moon; to make seed-plots when the moon is above the horizon; and to tread out the grape, to fell timber, and to do many other things that have been mentioned in their respective places, when the moon is below it.

The observation of the moon, in general, as already observed in the Second Book, is not so very easy, but what I am about here to state even rustics will be able to comprehend: so long as the moon is seen in the west, and during the earlier hours of the night, she will be on the increase, and one half of her disk will be perceived; but when the moon is seen to rise at sun-set and opposite to the sun, so that they are both perceptible at the same moment, she will be at fall. Again, as often as the moon rises in the east, and does not give her light in the earlier hours of the night, but shows herself during a portion of the day, she will be on the wane, and one half of her only will again be perceptible: when the moon has ceased to be visible, she is in conjunction, a period known to us as "interlunium." During the conjunction, the moon will be above the horizon the same time as the sun, for the whole of the first day: on the second, she will advance upon the night ten-twelfths of an hour and one-fourth of a twelfth; on the third day, the same as on the second, and * * * so on in succession up to the fifteenth day, the same proportional parts of an hour being added each day. On the fifteenth day she will be above the horizon all night, and below it all day. On the sixteenth, she will remain below the horizon ten-twelfths of an hour, and one-fourth of a twelfth, at the first hour of

the night, and so on in the same proportion day after day, up to the period of her conjunction; and thus, the same time which by remaining under the horizon, she withdraws from the first part of the night, she will add to the end of the night by remaining above the horizon. Her revolutions, too, will occupy thirty days one month, and twenty-nine the next, and so on alternately. Such is the theory of the revolutions of the moon.

Detailed table of contents

CHAP. 76. (33.)

THE THEORY OF THE WINDS.

The theory of the winds is of a somewhat more intricate nature. After observing the quarter in which the sun rises on any given day, at the sixth hour of the day take your position in such a manner as to have the point of the sun's rising on your left; you will then have the south directly facing you, and the north at your back: a line drawn through a field in this direction is called the "cardinal" line. The observer must then turn round, so as to look upon his shadow, for it will be behind him. Having thus changed his position, so as to bring the point of the sun's rising on that day to the right, and that of his setting to the left, it will be the sixth hour of the day, at the moment when the shadow straight before him is the shortest. Through the middle of this shadow, taken lengthwise, a furrow must be traced in the ground with a hoe, or else a line drawn with ashes, some twenty feet in length, say; in the middle of this line, or, in other words, at the tenth foot in it, a small circle must then be described: to this circle we may give the name of the "umbilicus," or "navel." That point in the line which lies on the side of the head of the shadow will be the point from which the north wind blows. You who are engaged in pruning trees, be it your care that the incisions made in the wood do not face this point; nor should the vine-trees or the vines have this aspect, except in the climates of Africa, Cyrenæ, or Egypt. When the wind blows, too, from this point, you must never plough, nor, in fact, attempt any other of the operations of which we shall have to make mention.

That part of the line which lies between the umbilicus and the feet of the shadow will look towards the south, and indicate the point from which the south wind blows, to which, as already mentioned, the Greeks have given the name of Notus. When the wind comes from this quarter, you, hasbandman, must never fell wood or touch the vine. In Italy this wind is either humid or else of a burning heat, and in Africa it is accompanied with intense heat and fine clear weather. In Italy the bearing branches should be trained to face this quarter, but the incisions made in the trees or vines when pruned must never face it. Let those be on their guard against this wind upon the four days at the rising of the Vergiliæ, who are engaged in planting the olive, as well as those who are employed in the operations of grafting or inoculating.

It will be as well, too, here to give some advice, in reference to the climate of Italy, as to certain precautions to be observed at certain hours of the day. You, woodman, must never lop the branches in the middle of the day; and you, shepherd, when you see midday approaching in summer, and the shadow gradually decreasing, drive your flocks from out of the sun into some well-shaded spot. When you lead the flocks to pasture in summer, let them face the west before midday, and after that time, the east: if this precaution is not

adopted, calamitous results will ensue; the same, too, if the flocks are led in winter or spring to pastures covered with dew. Nor must you let them feed with their faces to the north, as already mentioned; for the wind will either close their eyes or else make them bleared, and they will (lie of looseness. If you wish to have females, you should let the dams have their faces towards the north while being covered.

Detailed table of contents

CHAP. 77. (34.)

THE LAYING OUT OF LANDS ACCORDING TO THE POINTS OF THE WIND.

We have already stated that the umbilicus should be described in the middle of the line. Let another line be drawn transversely through the middle of it, and it will be found to run from due east to due west; a trench cut through the land in accordance with this line is known by the name of “decumanus.” Two other lines must then be traced obliquely across them in the form of the letter X, in such a way as to run exactly from right and left of the northern point to left and right of the southern one. All these lines must pass through the centre of the umbilicus, and all must be of corresponding length, and at equal distances. This method should always be adopted in laying out land; or if it should be found necessary to employ it frequently, a plan of it may be made in wood, sticks of equal length being fixed upon the surface of a small tambour, but perfectly round. In the method which I am here explaining, it is necessary to point out one precaution that must always be observed by those who are unacquainted with the subject. The point that must be verified first of all is the south, as that is always the same; but the sun, it must be remembered, rises every day at a point in the heavens different to that of his rising on the day before, so that the east must never be taken as the basis for tracing the lines.

Having now ascertained the various points of the heavens, the extremity of the line that is nearest to the north, but lying to the east of it, will indicate the solstitial rising, or, in other words, the rising of the sun on the longest day, as also the point from which the wind Aquilo blows, known to the Greeks by the name of Boreas. You should plant all trees and vines facing this point, but take care never to plough, or sow corn, or plant in seed plots, while this wind is blowing, for it has the effect of drying up and blasting the roots of the trees while being transplanted. Be taught in time — one thing is good for grown trees, another for them while they are but young. Nor have I forgotten the fact, that it is at this point of the heavens that the Greeks place the wind, to which they give the name of Cæcias; Aristotle, a man of most extensive learning, who has assigned to Cæcias this position, explains that it is in consequence of the convexity of the earth, that Aquilo blows in an opposite direction to the wind called Africus.

The agriculturist, however, has nothing to fear from Aquilo, in respect to the operations before mentioned, all the year through; for this wind is softened by the sun in the middle of the summer, and, changing its name, is known by that of Etesias. When you feel the cold, then, be on your guard; for, whatever the noxious effects that are attributed to Aquilo, the more sensibly will they be felt when the wind blows from due north. In Asia, Greece, Spain, the coasts of Italy, Campania, and Apulia, the trees that support the vines, as well as the vines themselves, should have an aspect towards the north-east. If you wish to

have male produce, let the flock feed in such a way, that this wind may have the opportunity of fecundating the male, whose office it is to fecundate the females. The wind Africus, known to the Greeks by the name of Libs, blows from the south-west, the opposite point to Aquilo; when animals, after coupling, turn their heads towards this quarter, you may be sure that female produce has been conceived.

The third: line from the north, which we have drawn transversely through the shadow, and called by the name of “decumanus,” will point due east, and from this quarter the wind Subsolanus blows, by the Greeks called Apeliotes. It is to this point that, in healthy localities, farm-houses and vineyards are made to look. This wind is accompanied with soft, gentle showers; Favonius, however, the wind that blows from due west, the opposite quarter to it, is of a drier nature; by the Greeks it is known as Zephyrus. Cato has recommended that olive-yards should look due west. It is this wind that begins the spring, and opens the earth; it is moderately cool, but healthy. As soon as it begins to prevail, it indicates that the time has arrived for pruning the vine, weeding the corn, planting trees, grafting fruit-trees, and trimming the olive; for its breezes are productive of the most nutritious effects.

The fourth line from the north, and the one that lies nearest the south on the eastern side, will indicate the point of the sun’s rising at the winter solstice, and the wind Volturnus, known by the name of Eurus to the Greeks. This wind is warm and dry, and beehives and vineyards, in the climates of Italy and the Gallic provinces, should face this quarter. Directly opposite to Volturnus, the wind Corus blows; it indicates the point of the sun’s setting at the summer solstice, and lies on the western side next to the north. By the Greeks it is called Argestes, and is one of the very coldest of the winds, which, in fact, is the case with all the winds that blow from the north; this wind, too, brings hailstorms with it, for which reason it is necessary to be on our guard against it no less than the north. If Volturnus begins to blow from a clear quarter of the heavens, it will not last till night; but if it is Subsolanus, it will prevail for the greater part of the night. Whatever the wind that may happen to be blowing, if it is accompanied by heat, it will be sure to last for several days. The earth announces the approach of Aquilo, by drying on a sudden, while on the approach of Auster, the surface becomes moist without any apparent cause.

CHAP. 78. (35.)

PROGNOSTICS DERIVED FROM THE SUN.

Having now explained the theory of the winds, it seems to me the best plan, in order to avoid any repetition, to pass on to the other signs and prognostics that are indicative of a change of weather. I find, too, that this is a kind of knowledge that greatly interested Virgil, for he mentions the fact, that during the harvest even, he has often seen the winds engage in a combat that was absolutely ruinous to the improvident agriculturist. There is a tradition, too, to the effect that Democritus, already mentioned, when his brother Damasus was getting in his harvest in extremely hot weather, entreated him to leave the rest of the crop, and house with all haste that which had been cut; and it was only within a very few hours that his prediction was verified by a most violent storm. On the other hand, it is particularly recommended never to plant reeds except when rain is impending, and only to sow corn just before a shower; we shall therefore briefly touch upon the prognostics of this description, making enquiry more particularly into those among them that have been found the most useful.

In the first place, then, we will consider those prognostics of the weather which are derived from the sun. If the sun is bright at its rising, and not burning hot, it is indicative of fine weather, but if pale, it announces wintry weather accompanied with hail. If the sun is bright and clear when it sets, and it rises with a similar appearance, the more assured of fine weather may we feel ourselves. If it is hidden in clouds at its rising, it is indicative of rain, and of wind, when the clouds are of a reddish colour just before sunrise; if black clouds are intermingled with the red ones, they betoken rain as well. When the sun's rays at its rising or setting appear to unite, rainy weather may be looked for. When the clouds are red at sunset, they give promise of a fine day on the morrow; but if, at the sun's rising, the clouds are dispersed in various quarters, some to the south, and some to the north-east, even though the heavens in the vicinity of the sun may be bright, they are significant of rain and wind. If at the sun's rising or setting, its rays appear contracted, they announce the approach of a shower. If it rains at sunset, or if the sun's rays attract the clouds towards them, it is portentous of stormy weather on the following day. When the sun, at its rising, does not emit vivid rays, although there are no clouds surrounding it, rain may be expected. If before sunrise the clouds collect into dense masses, they are portentous of a violent storm; but if they are repelled from the east and travel westward, they indicate fine weather. When clouds are seen surrounding the face of the sun, the less the light they leave, the more violent the tempest will be: but if they form a double circle round the sun, the storm will be a dreadful one. If this takes place at sunrise or sunset, and the clouds assume a red hue, the approach of a most violent storm

is announced: and if the clouds hang over the face of the sun without surrounding it, they presage wind from the quarter from which they are drifting, and rain as well, if they come from the south.

If, at its rising, the sun is surrounded with a circle, wind may be looked for in the quarter in which the circle breaks; but if it disappears equally throughout, it is indicative of fine weather. If the sun at its rising throws out its rays afar through the clouds, and the middle of its disk is clear, there will be rain; and if its rays are seen before it rises, both rain and wind as well. If a white circle is seen round the sun at its setting, there will be a slight storm in the night; but if there is a mist around it, the storm will be more violent. If the sun is pale at sunset, there will be wind, and if there is a dark circle round it, high winds will arise in the quarter in which the circle breaks.

CHAP. 79.

PROGNOSTICS DERIVED FROM THE MOON.

The prognostics derived from the moon, assert their right to occupy our notice in the second place. In Egypt, attention is paid, more particularly, to the fourth day of the moon. If, when the moon rises, she shines with a pure bright light, it is generally supposed that we shall have fine weather; but if she is red, there will be wind, and if of a swarthy hue, rain. If upon the fifth day of the moon her horns are obtuse, they are always indicative of rain, but if sharp and erect, of wind, and this on the fourth day of the moon more particularly. If her northern horn is pointed and erect, it portends wind; and if it is the lower horn that presents this appearance, the wind will be from the south; if both of them are erect, there will be high winds in the night. If upon the fourth day of the moon she is surrounded by a red circle, it is portentous of wind and rain.

In Varro we find it stated to the following effect:— “If, at the fourth day of the moon, her horns are erect, there will be great storms at sea, unless, indeed, she has a circlet around her, and that circlet unblemished; for by that sign we are informed that there will be no stormy weather before full moon. If, at the full moon, one half of her disk is clear, it is indicative of fine weather, but if it is red, of wind, and if black, of rain. If a darkness comes over the face of the moon, covered with clouds, in whatever quarter it breaks, from that quarter wind may be expected. If a twofold circle surrounds the moon, the storm will be more violent, and even more so still, if there are three circles, or if they are black, broken, and disjointed. If the new moon at her rising has the upper horn obscured, there will be a prevalence of rainy weather, when she is on the wane; but if it is the lower horn that is obscured, there will be rain before full moon; if, again, the moon is darkened in the middle of her disk, there will be rain when she is at full. If the moon, when full, has a circle round her, it indicates wind from the quarter in the circle which is the brightest; but if at her rising the horns are obtuse, they are portentous of a frightful tempest. If, when the west wind prevails, the moon does not make her appearance before her fourth day, there will be a prevalence of stormy weather throughout the month. If on the sixteenth day the moon has a bright, flaming appearance, it is a presage of violent tempests.”

There are eight different epochs of the moon, or periods at which she makes certain angles of incidence with the sun, and most persons only notice the prognostics derived from the moon, according to the places which they occupy between these angles. The periods of these angles are the third day, the seventh, the eleventh, the fifteenth, the nineteenth, the twenty-third, the twenty-seventh, and that of the conjunction.

CHAP. 80.

PROGNOSTICS DERIVED FROM THE STARS.

In the third rank must be placed the prognostics derived from the stars. These bodies are sometimes to be seen shooting to and fro; when this happens, winds immediately ensue, in that part of the heavens in which the presage has been afforded. When the heavens are equally bright throughout their whole expanse, at the periods previously mentioned, the ensuing autumn will be fine and cool. If the spring and summer have passed not without some rain, the autumn will be fine and settled, and there will be but little wind: when the autumn is fine, it makes a windy winter. When the brightness of the stars is suddenly obscured, though without clouds or fog, violent tempests may be expected. If numerous stars are seen to shoot, leaving a white track behind them, they presage wind from that quarter. If they follow in quick succession from the same quarter, the wind will blow steadily, but if from various quarters of the heavens, the wind will shift in sudden gusts and squalls. If circles are seen to surround any of the planets, there will be rain. In the constellation of Cancer, there are two small stars to be seen, known as the Aselli, the small space that lies between them being occupied by a cloudy appearance, which is known as the Manger; when this cloud is not visible in a clear sky, it is a presage of a violent storm. If a fog conceals from our view the one of these stars which lies to the north-east, there will be high winds from the south; but if it is the star which lies to the south that is so obscured, then the wind will be from the north-east. The rainbow, when double, indicates the approach of rain; but if seen after rain, it gives promise, though by no means a certain one, of fine weather. Circular clouds around some of the stars are indicative of rain.

Detailed table of contents

CHAP. 81.

PROGNOSTICS DERIVED FROM THUNDER.

When, in summer, there is more thunder than lightning, wind may be expected from that quarter; but if, on the other hand, there is not so much thunder as lightning, there will be a fall of rain. When it lightens in a clear sky, there will be rain, and if there is thunder as well, stormy weather; but if it lightens from all four quarters of the heavens, there will be a dreadful tempest. When it lightens from the north-east only, it portends rain on the following day; but when from the north, wind may be expected from that quarter. When it lightens on a clear night from the south, the west, or the north-west, there will be wind and rain from those quarters. Thunder in the morning is indicative of wind, and at midday of rain.

Detailed table of contents

CHAP. 82.

PROGNOSTICS DERIVED FROM CLOUDS.

When clouds are seen moving in a clear sky, wind may be expected in the quarter from which they proceed; but if they accumulate in one spot, as they approach the sun they will disperse. If the clouds are dispersed by a north-east wind, it is a presage of high winds, but if by a wind from the south, of rain. If at sunset the clouds cover the heavens on either side of the sun, they are indicative of tempest; if they are black and lowering in the east, they threaten rain in the night, but if in the west, on the following day. If the clouds spread in large numbers from the east, like fleeces of wool in appearance, they indicate a continuance of rain for the next three days. When the clouds settle on the summits of the mountains, there will be stormy weather; but if the clouds clear away, it will be fine. When the clouds are white and lowering, a hailstorm, generally known as a “white” tempest, is close at hand. An isolated cloud, however small, though seen in a clear sky, announces wind and storm.

Detailed table of contents

CHAP. 83.

PROGNOSTICS DERIVED FROM MISTS.

Mists descending from the summits of mountains, or from the heavens, or settling in the vallies, give promise of fine weather.

Detailed table of contents

CHAP. 84.

PROGNOSTICS DERIVED FROM FIRE KINDLED BY MAN.

Next to these are the prognostics that are derived from fire kindled upon the earth. If the flames are pallid, and emit a murmuring noise, they are considered to presage stormy weather; and fungi upon the burning wick of the lamp are a sign of rain. If the flame is spiral and flickering, it is an indication of wind, and the same is the case when the lamp goes out of itself, or is lighted with difficulty. So, too, if the snuff hangs down, and sparks gather upon it, or if the burning coals adhere to vessels taken from off the fire, or if the fire, when covered up, sends out hot embers or emits sparks, or if the cinders gather into a mass upon the hearth, or the coals burn bright and glowing.

Detailed table of contents

CHAP. 85.

PROGNOSTICS DERIVED FROM WATER.

There are certain prognostics, too, that may be derived from water. If, when the sea is calm, the water ripples in the harbour, with a hollow, murmuring noise, it is a sign of wind, and if in winter, of rain as well. If the coasts and shores reecho while the sea is calm, a violent tempest may be expected; and the same when the sea, though calm, is heard to roar, or throws up foam and bubbling spray. If sea pulmones are to be seen floating on the surface, they are portentous of stormy weather for many days to come. Very frequently, too, the sea is seen to swell in silence, and more so than when ruffled by an ordinary breeze; this is an indication that the winds are at work within its bosom already.

Detailed table of contents

CHAP. 86.

PROGNOSTICS DERIVED FROM TEMPESTS THEMSELVES.

The reverberations, too, of the mountains, and the roaring of the forests, are indicative of certain phænomena; and the same is the case when the leaves are seen to quiver, without a breath of wind, the downy filaments of the poplar or thorn to float in the air, and feathers to skim along the surface of the water. In champaign countries, the storm gives notice of its approach by that peculiar muttering which precedes it; while the murmuring that is heard in the heavens affords us no doubtful presage of what is to come.

Detailed table of contents

CHAP. 87.

PROGNOSTICS DERIVED FROM AQUATIC ANIMALS, AND BIRDS.

The animals, too, afford us certain presages; dolphins, for instance, sporting in a calm sea, announce wind in the quarter from which they make their appearance. When they throw up the water in a billowy sea, they announce the approach of a calm. The loligo, springing out of the water, shell-fish adhering to various objects, sea-urchins fastening by their stickles upon the sand, or else burrowing in it, are so many indications of stormy weather: the same, too, when frogs croak more than usual, or coots make a chattering in the morning. Divers, too, and ducks, when they clean their feathers with the bill, announce high winds; which is the case also when the aquatic birds unite in flocks, cranes make for the interior, and divers and sea-mews forsake the sea or the creeks. Cranes when they fly aloft in silence announce fine weather, and so does the owlet, when it screeches during a shower; but it is heard in fine weather, it presages a storm. Ravens, too, when they croak with a sort of gurgling noise and shake their feathers, give warning of the approach of wind, if their note is continuous: but if, on the other hand, it is smothered, and only heard at broken intervals, we may expect rain, accompanied with high winds. Jackdaws, when they return late from feeding, give notice of stormy weather, and the same with the white birds, when they unite in flocks, and the land birds, when they descend with cries to the water and besprinkle themselves, the crow more particularly. The swallow, too, when it skims along the surface of the water, so near as to ripple it every now and then with its wings, and the birds that dwell in the trees, when they hide themselves in their nests, afford similar indications; geese, too, when they set up a continuous gabbling, at an unusual time, and the heron, when it stands moping in the middle of the sands.

Detailed table of contents

CHAP. 88.

PROGNOSTICS DERIVED FROM QUADRUPEDS.

Nor, indeed, is it surprising that the aquatic birds, or any birds, in fact, should have a perception of the impending changes of the atmosphere. Sheep, however, when they skip and frisk with their clumsy gambols, afford us similar prognostics; oxen, when they snuff upwards towards the sky, and lick themselves against the hair; unclean swine, when they tear to pieces the trusses of hay that are put for other animals; bees, when, contrary to their natural habits of industry, they keep close within the hive; ants, when they hurry to and fro, or are seen carrying forth their eggs; and earthworms, emerging from their holes — all these indicate approaching changes in the weather.

Detailed table of contents

CHAP. 89.

PROGNOSTICS DERIVED FROM PLANTS.

It is a well-known fact, that trefoil bristles up, and its leaves stand erect, upon the approach of a tempest.

Detailed table of contents

CHAP. 90.

PROGNOSTICS DERIVED FROM FOOD.

At our repasts, too, and upon our tables, when we see the vessels sweat in which the viands are served, and leave marks upon the side-board, it is an indication that a dreadful storm is impending.

SUMMARY. — Remarkable facts, narratives, and observations, two thousand and sixty.

ROMAN AUTHORS QUOTED. — Massurius Sabinus, Cassius Hemina, Verrius Flaccus, L. Piso, Cornelius Celsus, Turranius Gracilis, D. Silanus, M. Varro, Cato the Censor, Scrofa, the Sasernœ, father and son, Domitius Calvinus, Hyginus, Virgil, Trogus, Ovid, Græcinus, Columella, Tubero, L. Tarutius, who wrote in Greek on the Stars, Cæsar the Dictator, who wrote upon the Stars, Sergius Paulus, Sabinus Fabianus, M. Cicero, Calpurnius Bassus, Ateius Capito, Mamilius Sura, Attius, who wrote the Praxidica.

FOREIGN AUTHORS QUOTED. — Hesiod, Theophrastus, Aristotle, Democritus, King Hiero, King Attalus Philometor, King Archelaüs, Archytas, Xenophon, Amphilochus of Athens, Anaxipolis of Thasos, Aristophanes of Miletus, Apollodorus of Lemnos, Antigonus of Cymæ, Agathocles of Chios, Apollonius of Pergamus, Aristander of Athens, Bacchius of Miletus, Bion of Soli, Chæreas of Athens, Chæristus of Athens, Diodorus of Priene, Dion of Colophon, Epigenes of Rhodes, Euagon of Thasos, Euphronius of Athens, Androtion who wrote on Agriculture, Æschrion who wrote on Agriculture, Lysimachus who wrote on Agriculture, Dionysius who translated Mago, Diophanes who made an Epitome from Dionysius, Thales, Eudoxus, Philippus, Calippus, Dositheus, Parmeniscus, Meton, Criton, Cænopides, Zenon, Euctemon, Harpalus, Hecatæus, Anaximander, Sosigenes, Hipparchus, Aratus, Zoroaster, Archibius.

Detailed table of contents

**BOOK XIX. THE NATURE AND CULTIVATION OF
FLAX, AND AN ACCOUNT OF VARIOUS GARDEN
PLANTS.**

Detailed table of contents

CHAP. 1.

THE NATURE OF FLAX — MARVELLOUS FACTS RELATIVE THERETO.

WE have now imparted a knowledge of the constellations and of the seasons, in a method unattended with difficulty for the most ignorant even, and free from every doubt; indeed, to those who understand these matters aright, the face of the earth contributes in no less a degree to a due appreciation of the celestial phenomena, than does the science of astronomy to our improvement in the arts of agriculture.

Many writers have made it their next care to treat of horticulture; but, for my own part, it does not appear to me altogether advisable to pass on immediately to that subject, and, indeed, I am rather surprised to find that some among the learned, who have either sought the pleasures of knowledge in these pursuits, or have grounded their celebrity upon them, have omitted so many particulars in reference thereto; for no mention do we find in their writings of numerous vegetable productions, both wild as well as cultivated, many of which are found, in ordinary life, to be of higher value and of more extended use to man than the cereals even.

To commence, then, with a production which is of an utility that is universally recognized, and is employed not only upon dry land but upon the seas as well, we will turn our attention to flax, a plant which is reproduced from seed, but which can neither be classed among the cereals nor yet among the garden plants. What department is there to be found of active life in which flax is not employed? and in what production of the earth are there greater marvels revealed to us than in this? To think that here is a plant which brings Egypt in close proximity to Italy! — so much so, in fact, that Galerius and Balbillus, both of them prefects of Egypt, made the passage to Alexandria from the Straits of Sicily, the one in six days, the other in five! It was only this very last summer, that Valerius Marianus, a senator of prætorian rank, reached Alexandria from Puteoli in eight days, and that, too, with a very moderate breeze all the time! To think that here is a plant which brings Gades, situate near the Pillars of Hercules, within six days of Ostia, Nearer Spain within three, the province of Gallia Narbonensis within two, and Africa within one! — this last passage having been made by C. Flavius, when legatus of Vibius Crispus, the proconsul, and that, too, with but little or no wind to favour his passage!

What audacity in man! What criminal perverseness! thus to sow a thing in the ground for the purpose of catching the winds and the tempests, it being not enough for him, forsooth, to be borne upon the waves alone! Nay, still more than this, sails even that are bigger than the very ships themselves will not suffice for him, and although it takes a whole tree to make a mast to carry the cross-yards, above those cross-yards sails upon sails must still be added, with

others swelling at the prow and at the stern as well — so many devices, in fact, to challenge death! Only to think, in fine, that that which moves to and fro, as it were, the various countries of the earth, should spring from a seed so minute, and make its appearance in a stem so fine, so little elevated above the surface of the earth! And then, besides, it is not in all its native strength that it is employed for the purposes of a tissue; no, it must first be rent asunder, and then tawed and beaten, till it is reduced to the softness of wool; indeed, it is only by such violence done to its nature, and prompted by the extreme audacity of man, and * * * that it is rendered subservient to his purposes. The inventor of this art has been already mentioned by us on a more appropriate occasion; not satisfied that his fellow-men should perish upon land, but anxious that they should meet their end with no sepulchral rites to await them, there are no execrations to be found that can equal his demerits!

It is only in the preceding Book that I was warning the agriculturist, as he values the grain that is to form our daily sustenance, to be on his guard against the storm and the tempest; and yet, here we have man sowing with his own hand, man racking his invention how best to gather, an object the only aspirations of which upon the deep are the winds of heaven! And then, too, as if to let us understand all the better how highly favoured is this instrument of our punishment, there is no vegetable production that grows with greater facility; and, to prove to us that it is in despite of Nature herself that it exists, it has the property of scorching the ground where it is grown, and of deteriorating the quality of the very soil itself.

Detailed table of contents

CHAP. 2. (1.)

HOW FLAX IS SOWN: TWENTY-SEVEN PRINCIPAL VARIETIES OF IT.

Flax is mostly sown in sandy soils, and after a single ploughing only. There is no plant that grows more rapidly than this; sown in spring, it is pulled up in summer, and is, for this reason as well, productive of considerable injury to the soil. There may be some, however, who would forgive Egypt for growing it, as it is by its aid that she imports the merchandize of Arabia and India; but why should the Gallic provinces base any of their reputation upon this product? Is it not enough, forsooth, for them to be separated by mountains from the sea, and to have, upon the side on which they are bounded by the Ocean, that void and empty space, as it is called? The Cadurci, the Caleti, the Ruteni, the Bituriges, and the Morini, those remotest of all mankind, as it is supposed, the whole of the Gallic provinces, in fact, are in the habit of weaving sail-cloth; and at the present day our enemies even, who dwell beyond the Rhenus, have learned to do the same; indeed, there is no tissue that is more beautiful in the eyes of their females than linen. I am here reminded of the fact, that we find it stated by M. Varro, that it is a custom peculiar to the family of the Serrani for the women never to wear garments of linen. In Germany it is in caves deep underground that the linen-weavers ply their work; and the same is the case, too, in the Albian territory, in Italy, between the rivers Padus and Ticinus, the linen of which holds the third rank among the kinds manufactured in Europe, that of Sætabis claiming the first, and those of Retovium and of Faventia, in the vicinity of Alia, on the Æmilian Way, the second, place in general estimation. The linens of Faventia are preferred for whiteness to those of Alia, which are always unbleached: those of Retovium are remarkable for their extreme fineness, combined with substance, and are quite equal in whiteness to the linens of Faventia; but they have none of that fine downy nap upon them, which is so highly esteemed by some persons, though equally disliked by others. A thread is made, too, from their flax, of considerable strength, smoother and more even, almost, than the spider's web; when tested with the teeth, it emits a sharp, clear twang; hence it is, that it sells at double the price of the other kinds.

But it is the province of Nearer Spain that produces a linen of the greatest lustre, an advantage which it owes to the waters of a stream which washes the city of Tarraco there. The fineness, too, of this linen is quite marvellous, and here it is that the first manufactories of cambric were established. From the same province, too, of Spain, the flax of Zoëla has of late years been introduced into Italy, and has been found extremely serviceable for the manufacture of hunting-nets. Zoëla is a city of Callæcia, in the vicinity of the Ocean. The flax, too, of Cumæ, in Campania, has its own peculiar merits in the manufacture of nets for fishing and fowling; it is employed, also, for

making hunting-nets. For it is from flax, in fact, that we prepare various textures, destined to be no less insidious to the brute creation than they are to ourselves. It is with toils made from the flax of Cumæ that wild boars are taken, the meshes being proof against their bristles, equally with the edge of the knife: before now, too, we have seen some of these toils of a fineness so remarkable as to allow of being passed through a man's ring, running ropes and all, a single individual being able to carry an amount of nets sufficient to environ a whole forest — a thing which we know to have been done not long ago by Julius Lupus, who died prefect of Egypt. This, however, is nothing very surprising, but it really is quite wonderful that each of the cords was composed of no less than one hundred and fifty threads. Those, no doubt, will be astonished at this, who are not aware that there is preserved in the Temple of Minerva, at Lindus, in the Isle of Rhodes, the cuirass of a former king of Egypt, Amasis by name, each thread employed in the texture of which is composed of three hundred and sixty-five other threads. Mucianus, who was three times consul, informs us that he saw this curiosity very recently, though there was but little then remaining of it, in consequence of the injury it had experienced at the hands of various persons who had tried to verify the fact. Italy, too, holds the flax of the Peligni in high esteem, though it is only employed by fullers; there is no kind known that is whiter than this, or which bears a closer resemblance to wool. That grown by the Cadurci is held in high estimation for making mattresses; which, as well as flock, are an invention for which we are indebted to the Gauls: the ancient usage of Italy is still kept in remembrance in the word "stramentum," the name given by us to beds stuffed with straw.

The flax of Egypt, though the least strong of all as a tissue, is that from which the greatest profits are derived. There are four varieties of it, the Tanitic, the Pelusiatic, the Butic, and the Tentyritic — so called from the various districts in which they are respectively grown. The upper part of Egypt, in the vicinity of Arabia, produces a shrub, known by some as "gossypium," but by most persons as "xylon;" hence the name of "xylina," given to the tissues that are manufactured from it. The shrub is small, and bears a fruit, similar in appearance to a nut with a beard, and containing in the inside a silky substance, the down of which is spun into threads. There is no tissue known, that is superior to those made from this thread, either for whiteness, softness, or dressing: the most esteemed vestments worn by the priests of Egypt are made of it. There is a fourth kind of tissue, known by the name of "othoninum," which is made from a kind of marshreed, the panicle only being employed for the purpose. In Asia, again, there is a thread made from broom, which is employed in the construction of fishing-nets, being found to be remarkably durable; for the purpose of preparing it, the shrub is steeped in water for ten days. The Æthiopians, also, and the people of India, prepare a kind of thread from a fruit which resembles our apple, and the Arabians, as already mentioned, from gourds that grow upon trees.

CHAP. 3.

THE MODE OF PREPARING FLAX.

In our part of the world the ripeness of flax is usually ascertained by two signs, the swelling of the seed, and its assuming a yellowish tint. It is then pulled up by the roots, made up into small sheaves that will just fill the hand, and hung to dry in the sun. It is suspended with the roots upwards the first day, and then for the five following days the heads of the sheaves are placed, reclining one against the other, in such a way that the seed which drops out may fall into the middle. Linseed is employed for various medicinal purposes, and it is used by the country-people of Italy beyond the Padus in a certain kind of food, which is remarkable for its sweetness: for this long time past, however, it has only been in general use for sacrifices offered to the divinities. After the wheat harvest is over, the stalks of flax are plunged in water that has been warmed in the sun, and are then submitted to pressure with a weight; for there is nothing known that is more light and buoyant than this. When the outer coat is loosened, it is a sign that the stalks have been sufficiently steeped; after which they are again turned with the heads downwards, and left to dry as before in the sun: when thoroughly dried, they are beaten with a tow-mallet on a stone.

The part that lies nearest to the outer coat is known by the name of “stuppa;” it is a flax of inferior quality, and is mostly employed for making the wicks of lamps. This, however, requires to be combed out with iron hatchels, until the whole of the outer skin is removed. The inner part presents numerous varieties of flax, esteemed respectively in proportion to their whiteness and their softness. Spinning flax is held to be an honourable employment for men even: the husks, or outer coats, are employed for heating furnaces and ovens. There is a certain amount of skill required in hatchelling flax and dressing it: it is a fair proportion for fifty pounds in the sheaf to yield fifteen pounds of flax combed out. When spun into thread, it is rendered additionally supple by being soaked in water and then beaten out upon a stone; and after it is woven into a tissue, it is again beaten with heavy maces: indeed, the more roughly it is treated the better it is.

CHAP. 4.

LINEN MADE OF ASBESTOS.

There has been invented also a kind of linen which is incombustible by flame. It is generally known as “live” linen, and I have seen, before now, napkins that were made of it thrown into a blazing fire, in the room where the guests were at table, and after the stains were burnt out, come forth from the flames whiter and cleaner than they could possibly have been rendered by the aid of water. It is from this material that the corpse-cloths of monarchs are made, to ensure the separation of the ashes of the body from those of the pile. This substance grows in the deserts of India, scorched by the burning rays of the sun: here, where no rain is ever known to fall, and amid multitudes of deadly serpents, it becomes habituated to resist the action of fire. Rarely to be found, it presents considerable difficulties in weaving it into a tissue, in consequence of its shortness; its colour is naturally red, and it only becomes white through the agency of fire. By those who find it, it is sold at prices equal to those given for the finest pearls; by the Greeks it is called “asbestinon,” a name which indicates its peculiar properties. Anaxilaüs makes a statement to the effect that if a tree is surrounded with linen made of this substance, the noise of the blows given by the axe will be deadened thereby, and that the tree may be cut down without their being heard. For these qualities it is that this linen occupies the very highest rank among all the kinds that are known.

The next rank is accorded to the tissue known as “byssus,” an article which is held in the very highest estimation by females, and is produced in the vicinity of Elis, in Achaia. I find it stated by some writers that a scruple of this sold formerly at four denarii, the same rate, in fact, as gold. The downy nap of linen, and more particularly that taken from the sails of sea-going ships, is very extensively employed for medicinal purposes, and the ashes of it have the same virtues as spodium. Among the poppies, too, there is a variety which imparts a remarkable degree of whiteness to fabrics made of linen.

Detailed table of contents

CHAP. 5.

AT WHAT PERIOD LINEN WAS FIRST DYED.

Attempts, too, have even been made to dye linen, and to make it assume the frivolous colours of our cloths. This was first done in the fleet of Alexander the Great, while sailing upon the river Indus; for, upon one occasion, during a battle that was being fought, his generals and captains distinguished their vessels by the various tints of their sails, and astounded the people on the shores by giving their many colours to the breeze, as it impelled them on. It was with sails of purple, too, that Cleopatra accompanied M. Antonius to the battle of Actium, and it was by their aid that she took to flight: such being the distinguishing mark of the royal ship.

Detailed table of contents

CHAP. 6.

AT WHAT PERIOD COLOURED AWNINGS WERE FIRST EMPLOYED IN THE THEATRES.

In more recent times linens alone have been employed for the purpose of affording shade in our theatres; Q. Catulus having been the first who applied them to this use, on the occasion of the dedication by him of the Capitol. At a later period, Lentulus Spinther, it is said, was the first to spread awnings of fine linen over the theatre, at the celebration of the Games in honour of Apollo. After this, Cæsar, when Dictator, covered with a linen awning the whole of the Roman Forum, as well as the Sacred Way, from his own house as far as the ascent to the Capitol, a sight, it is said, more wonderful even than the show of gladiators which he then exhibited. At a still later period, and upon the occasion of no public games, Marcellus, the son of Octavia, sister of Augustus, during his ædileship, and in the eleventh consulship of his uncle, on the * * * day before the calends of August, covered in the Forum with awnings, his object being to consult the health of those assembled there for the purposes of litigation — a vast change, indeed, from the manners prevalent in the days of Cato the Censor, who expressed a wish that the Forum was paved with nothing else but sharp pointed stones.

Awnings have been lately extended, too, by the aid of ropes, over the amphitheatres of the Emperor Nero, dyed azure, like the heavens, and bespangled all over with stars. Those which are employed by us to cover the inner court of our houses are generally red: one reason for employing them is to protect the moss that grows there from the rays of the sun. In other respects, white fabrics of linen have always held the ascendancy in public estimation. Linen, too, was highly valued as early as the Trojan war; for why else should it not have figured as much in battles as it; did in shipwrecks? Thus Homer, we find, bears witness that there were but few among the warriors of those days who fought with cuirasses on made of linen; while, as for the rigging of the ships, of which that writer speaks, it is generally supposed by the more learned among the commentators, that it was made of this material; for the word “sparta,” which he employs, means nothing more than the produce of a seed.

CHAP. 7. (2.)

THE NATURE OF SPARTUM.

For the fact is that spartum did not begin to be employed till many ages after the time of Homer; indeed, not before the first war that the Carthaginians waged in Spain. This, too, is a plant that grows spontaneously, and is incapable of being reproduced by sowing, it being a species of rush, peculiar to a dry, arid soil, a morbid production confined to a single country only; for in reality it is a curse to the soil, as there is nothing whatever that can be sown or grown in its vicinity. There is a kind of spartum grown in Africa, of a stunted nature, and quite useless for all practical purposes. It is found in one portion of the province of Carthage in Nearer Spain, though not in every part of that; but wherever it is produced, the mountains, even, are covered all over with it.

This material is employed by the country-people there for making their beds; with it they kindle their fires also, and prepare their torches; shoes also, and garments for the shepherds, are made of it. As a food for animals, it is highly injurious, with the sole exception of the tender tops of the shoots. When wanted for other uses, it is pulled up by the roots, with considerable labour; the legs of the persons so employed being protected by boots, and their hands with gloves, the plant being twisted round levers of bone or holm-oak, to get it up with the greater facility. At the present day it is gathered in the winter, even; but this work is done with the least difficulty between the ides of May and those of June, that being the period at which it is perfectly ripe.

Detailed table of contents

CHAP. 8.

THE MODE OF PREPARING SPARTUM.

When taken up it is made into sheaves, and laid in heaps for a couple of days, while it retains its life and freshness; on the third day the sheaves are opened out and spread in the sun to dry, after which it is again made up into sheaves, and placed under cover. It is then put to soak in sea-water, this being the best of all for the purpose, though fresh water will do in case sea-water cannot be procured: this done, it is again dried in the sun, and then moistened afresh. If it is wanted for immediate use, it is put in a tub and steeped in warm water, after which it is placed in an upright position to dry: this being universally admitted to be the most expeditious method of preparing it. To make it ready for use, it requires to be beaten out. Articles made of it are proof, more particularly, against the action of fresh or sea-water; but on dry land, ropes of hemp are generally preferred. Indeed, we find that spartum receives nutriment even from being under water, by way of compensation, as it were, for the thirst it has had to endure upon its native soil.

By nature it is peculiarly well adapted for repairing, and however old the material may be, it unites very well with new. The person, indeed, who is desirous duly to appreciate this marvellous plant, has only to consider the numerous uses to which, in all parts of the world, it is applied: from it are made, the rigging of ships, various appliances of mechanism employed in building, and numerous other articles which supply the wants of daily life. To suffice for all these requirements, we find it growing solely on a tract of ground which lies upon the sea-line of the province of New Carthage, somewhat less than thirty miles in breadth by one hundred in length. The expense precludes its being transported to any very considerable distance.

[Detailed table of contents](#)

CHAP. 9.

AT WHAT PERIOD SPARTUM WAS FIRST EMPLOYED.

The Greeks used formerly to employ the rush for making ropes; so, at least, we are led to believe, from the name given by them to that plant; and at a later period they made them, it is very clear, from the leaves of the palm, and the inner bark of the linden-tree. It seems to me very probable, too, that it was from them that the Carthaginians borrowed the first hint for applying spartum to a similar purpose.

Detailed table of contents

CHAP. 10.

THE BULB ERIOPHORUS.

Theophrastus informs us, that there is a kind of bulb, which grows on the banks of rivers, and which encloses between the outer coat and the portion that is eaten a sort of woolly substance, of which felt socks, and other articles of dress, are made; but, in the copies, those at least which have fallen in my way, there is no mention made of the country in which it grows, or of any details in connection with it, beyond the fact that the name given to it is “eriophoron.” As to spartum, he makes no mention of it whatever, although he has given the history, with the greatest exactness, of all the known plants, three hundred and ninety years before our time — a fact to which I have already alluded on other occasions: from this it would appear that spartum has come into use since his day.

Detailed table of contents

CHAP. 11.

PLANTS WHICH SPRING UP AND GROW WITHOUT A ROOT — PLANTS WHICH GROW, BUT CANNOT BE REPRODUCED FROM SEED.

As we have here made a beginning of treating of the marvels of Nature, we shall proceed to examine them in detail; and among them the very greatest of all, beyond a doubt, is the fact that any plant should spring up and grow without a root. Such, for instance, is the vegetable production known as the truffle; surrounded on every side by earth, it is connected with it by no fibres, not so much as a single thread even, while the spot in which it grows, presents neither protuberance nor cleft to the view. It is found, in fact, in no way adhering to the earth, but enclosed within an outer coat; so much so, indeed, that though we cannot exactly pronounce it to be composed of earth, we must conclude that it is nothing else but a callous concretion of the earth.

Truffles generally grow in dry, sandy soils, and spots that are thickly covered with shrubs; in size they are often larger than a quince, and are found to weigh as much as a pound. There are two kinds of them, the one full of sand, and consequently injurious to the teeth, the other free from sand and all impurities. They are distinguished also by their colour, which is red or black, and white within; those of Africa are the most esteemed. Whether the truffle grows gradually, or whether this blemish of the earth — for it can be looked upon as nothing else — at once assumes the globular form and magnitude which it presents when found; whether, too, it is possessed of vitality or not, are all of them questions, which, in my opinion, are not easy to be solved. It decays and rots in a manner precisely similar to wood.

It is known to me as a fact, that the following circumstance happened to Lartius Licinius, a person of prætorian rank, while minister of justice, a few years ago, at Carthage in Spain; upon biting a truffle, he found a denarius inside, which all but broke his fore teeth — an evident proof that the truffle is nothing else but an agglomeration of elementary earth. At all events, it is quite certain that the truffle belongs to those vegetable productions which spring up spontaneously, and are incapable of being reproduced from seed.

CHAP. 12. (3.)

MISY; ITON; AND GERANION.

Of a similar nature, too, is the vegetable production known in the province of Cyrenaica by the name of “misy,” remarkable for the sweetness of its smell and taste, but more fleshy than the truffle: the same, too, as to the iton of the Thracians, and the geranion of the Greeks.

Detailed table of contents

CHAP. 13.

PARTICULARS CONNECTED WITH THE TRUFFLE.

The following peculiarities we find mentioned with reference to the truffle. When there have been showers in autumn, and frequent thunder-storms, truffles are produced, thunder contributing more particularly to their developement; they do not, however, last beyond a year, and are considered the most delicate eating when gathered in spring. In some places the formation of them is attributed to water; as at Mytilene, for instance, where they are never to be found, it is said, unless the rivers overflow, and bring down the seed from Tiara, that being the name of a place at which they are produced in the greatest abundance. The finest truffles of Asia are those found in the neighbourhood of Lampsacus and Alopecconesus; the best in Greece are those of the vicinity of Elis.

CHAP. 14.

THE PEZICA.

Belonging to the mushroom genus, also, there is a species, known to the Greeks by the name of “pezica,” which grows without either root or stalk.

Detailed table of contents

CHAP. 15.

LASERPITIUM, LASER, AND MASPETUM.

Next to these, laserpitium claims our notice, a very remarkable plant, known to the Greeks by the name of “silphion,” and originally a native of the province of Cyrenaica. The juice of this plant is called “laser,” and it is greatly in vogue for medicinal as well as other purposes, being sold at the same rate as silver. For these many years past, however, it has not been found in Cyrenaica, as the farmers of the revenue who hold the lands there on lease, have a notion that it is more profitable to depasture flocks of sheep upon them. Within the memory of the present generation, a single stalk is all that has ever been found there, and that was sent as a curiosity to the Emperor Nero. If it so happen that one of the flock, while grazing, meets with a growing shoot of it, the fact is easily ascertained by the following signs; the sheep, after eating of it, immediately falls asleep, while the goat is seized with a fit of sneezing. For this long time past, there has been no other laser imported into this country, but that produced in either Persis, Media, or Armenia, where it grows in considerable abundance, though much inferior to that of Cyrenaica; and even then it is extensively adulterated with gum, sacopenium, or pounded beans. I ought the less then to omit the facts, that in the consulship of C. Valerius and M. Herennius, there was brought to Rome, from Cyrenæ, for the public service, thirty pounds’ weight of laserpitium, and that the Dictator Cæsar, at the beginning of the Civil War, took from out of the public treasury, besides gold and silver, no less than fifteen hundred pounds of laserpitium.

We find it stated by the most trustworthy among the Greek writers, that this plant first made its appearance in the vicinity of the gardens of the Hesperides and the Greater Syrtis, immediately after the earth had been soaked on a sudden by a shower as black as pitch. This took place seven years before the foundation of the city of Cyrenæ, and in the year of Rome 143. The virtues of this remarkable fall of rain extended, it is said, over no less than four thousand stadia of the African territory; and upon this soil laserpitium began universally to grow, a plant that is in general wild and stubborn, and which, it attempted to be cultivated, will leave the spot where it has been sown quite desolate and barren. The roots of it are numerous and thick, the stalk being like that of fennel-giant, and of similar thickness. The leaves of this plant were known as “maspetum,” and bore a considerable resemblance to parsley; the seeds of it were foliaceous, and the plant shed its leaves every year. They used to feed the cattle there upon it; at first it purged them, but afterwards they would grow fat, the flesh being improved in flavour in a most surprising degree. After the fall of the leaf, the people themselves were in the habit of eating the stalk, either roasted or boiled: from the drastic effects of this diet the body was purged for the first forty days, all vicious humours being effectually removed.

The juices of this plant were collected two different ways, either from the root or from the stalk; in consequence of which these two varieties of the juice were known by the distinguishing names of “rhizias” and “caulias,” the last being of inferior quality to the other, and very apt to turn putrid. Upon the root there was a black bark, which was extensively employed for the purposes of adulteration. The juice of the plant was received in vessels, and mixed there with a layer of bran; after which, from time to time it was shaken, till it had reached a proper state of maturity; indeed, if this precaution was neglected, it was apt to turn putrid. The signs that it had come to maturity were its colour, its dryness, and the absorption of all humidity.

There are some authors, however, who state that the root of laserpitium was more than a cubit in length, and that it presented a tuberosity above the surface of the earth. An incision, they say, was made in this tuberosity, from which a juice would flow, like milk in appearance; above the tuberosity grew a stalk, to which they give the name of “magydaris;” the leaves that grew upon this stalk were of the colour of gold, and, falling at the rising of the Dog-star, when the south winds begin to prevail, they acted as seed for the purposes of reproduction. It was from these leaves, too, they say, that laserpitium was produced, the root and the stalk attaining their full growth in the space of one year. The same writers also state, that it was the practice to turn up the ground about the plant, and that it had no such effect as purging the cattle that were fed upon it; though one result of using it as food was, that such cattle as were ailing were either cured of their distempers, or else died immediately upon eating of it, a thing, however, that but rarely happened. The first description, however, is found to agree more nearly with the silphium that comes from Persis.

Detailed table of contents

CHAP. 16.

MAGYDARIS.

There is another variety of this plant, known as “magydaris,” of a more delicate nature, less active in its effects, and destitute of juice. It grows in the countries adjacent to Syria, but is not to be found in the regions of Cyrenaica. There grows also upon Mount Parnassus, in great abundance, a plant to which some persons give the name of “laserpitium:” by means of all these varieties, adulterations are effected of a production that is held in the highest esteem for its salutary qualities and its general usefulness. The chief proofs of its genuineness consist in its colour, which ought to be slightly red without, and when broken quite white and transparent within; the drops of it, too, should melt very rapidly on the application of spittle. It is extensively employed for medi- cinal purposes.

Detailed table of contents

CHAP. 17.

MADDER.

There are two other plants also, which are but little known to any but the herd of the sordid and avaricious, and this because of the large profits that are derived from them. The first of these is madder, the employment of which is necessary in dyeing wool and leather. The madder of Italy is the most esteemed, and that more particularly which is grown in the suburbs of the City; nearly all our provinces, too, produce it in great abundance. It grows spontaneously, but is capable of reproduction by sowing, much after the same manner as the fitch. The stem, however, is prickly, and articulated, with five leaves arranged round each joint: the seed is red. Its medicinal properties we shall have occasion to mention in the appropriate place.

Detailed table of contents

CHAP. 18.

THE RADICULA.

The plant known to us by the name of “radicula,” is the second of these productions. It furnishes a juice that is extensively employed in washing wool, and it is quite wonderful how greatly it contributes to the whiteness and softness of wool. It may be produced anywhere by cultivation, but that which grows spontaneously in Asia, and Syria, upon rugged, rocky sites, is more highly esteemed. That, however, which is found beyond the Euphrates has the highest repute of all. The stalk of it is ferulaceous and thin, and is sought by the inhabitants of those countries as an article of food. It is employed also for making unguents, being boiled up with the other ingredients, whatever they may happen to be. In leaf it strongly resembles the olive. The Greeks have given it the name of “struthion.” It blossoms in summer, and is agreeable to the sight, but entirely destitute of smell. It is somewhat thorny, and has a stalk covered with down. It has an extremely diminutive seed, and a large root, which is cut up and employed for the purposes already mentioned.

Detailed table of contents

CHAP. 19. (4.)

THE PLEASURES OF THE GARDEN.

Having made mention of these productions, it now remains for us to return to the cultivation of the garden, a subject recommended by its own intrinsic merits to our notice: for we find that in remote antiquity, even, there was nothing looked upon with a greater degree of admiration than the gardens of the Hesperides, those of the kings Adonis and Alci- noüs, and the Hanging Gardens, whether they were the work of Semiramis, or whether of Cyrus, king of Assyria, a subject of which we shall have to speak in another work. The kings of Rome cultivated their gardens with their own hands; indeed, it was from his garden that Tarquinius Superbus sent to his son that cruel and sanguinary message of his. In our laws of the Twelve Tables, we find the word “villa,” or “farm,” nowhere mentioned; it is the word “hortus” that is always used with that signification, while the term “heredium” we find employed for “garden.”

There are certain religious impressions, too, that have been attached to this species of property, and we find that it is in the garden and the Forum only that statues of satyrs are con- secrated, as a protection against the evil effects of spells and sorcery; although in Plautus, we find the gardens spoken of as being under the tutelage of Venus. At the present day, under the general name of gardens, we have pleasure-grounds situate in the very heart of the City, as well as extensive fields and villas.

Epicurus, that connoisseur in the enjoyments of a life of ease, was the first to lay out a garden at Athens; up to his time it had never been thought of, to dwell in the country in the middle of the town. At Rome, on the other hand, the garden constituted of itself the poor man’s field, and it was from the garden that the lower classes procured their daily food — an aliment how guiltlessly obtained! But still, it is a great deal better, no doubt, to dive into the abysses of the deep, and to seek each kind of oyster at the risk and peril of shipwreck, to go searching for birds beyond the river Phasis even, which, protected as they are by the terrors invented by fable, are only rendered all the more precious thereby — to go searching for others, again, in Numidia, and the very sepulchres of Æthiopia, or else to be battling with wild beasts, and to get eaten one’s self while trying to take a prey which another person is to eat! And yet, by Hercules! how little do the productions of the garden cost us in comparison with these! How more than sufficient for every wish and for every want! — were it not, indeed, that here, as in every thing else, turn which way we will, we find the same grounds for our wrath and in- dignation. We really might be content to allow of fruits being grown of the most exquisite quality, remarkable, some of them for their flavour, some for their size, some, again, for the monstrosities of their growth, morsels all of them forbidden to the

poor! We might allow of wines being kept till they are mellowed with age, or enfeebled by being passed through cloth strainers, of men, too, however prolonged their lives, never drinking any but a wine that is still older than themselves! We might allow of luxury devising how best to extract the very aroma, as it were, and marrow only from grain; of people, too, living upon nothing but the choicest productions of the confectioner, and upon pastes fashioned in fantastic shapes: of one kind of bread being prepared for the rich, and another for the multitude; of the yearly produce of the field being classified in a descending scale, till it reaches the humble means of the very lowest classes — but do we not find that these refined distinctions have been extended to the very herbs even, and that riches have contrived to establish points of dissimilarity in articles of food which ordinarily sell for a single copper coin?

In this department even, humble as it is, we are still destined to find certain productions that are denied to the community at large, and the very cabbages pampered to such an enormous extent that the poor man's table is not large enough to hold them. Asparagus, by Nature, was intended to grow wild, so that each might gather it where he pleased — but, lo and behold! we find it in the highest state of cultivation, and Ravenna produces heads that weigh as much as three pounds even! Alas for the monstrous excess of gluttony! It would be surprising indeed, for the beasts of the field to be forbidden the thistle for food, and yet it is a thing forbidden to the lower classes of the community! These refined distinctions, too, are extended to the very water even, and, thanks to the mighty influence of money, there are lines of demarcation drawn in the very elements themselves. Some persons are for drinking ice, others for quaffing snow, and thus is the curse of the mountain steep turned into an appetizing stimulus for the palate! Cold is carefully treasured up for the summer heats, and man's invention is racked how best to keep snow freezing in months that are not its own. Some again there are who first boil the water, and then bring it to the temperature of winter — indeed, there is nothing that pleases man in the fashion in which Nature originally made it.

And is it the fact, then, that any herb of the garden is reared only for the rich man's table? It is so — but still let no one of the angered populace think of a fresh secession to Mount Sacer or Mount Aventine; for to a certainty, in the long run, all-powerful money will bring them back to just the same position as they were in when it wrought the severance. For, by Hercules! there was not an impost levied at Rome more grievous than the market-dues, an impost that aroused the indignation of the populace, who repeatedly appealed with loud clamours to all the chief men of the state to be relieved from it. At last they were relieved from this heavy tax upon their wares; and then it was found that there was no tax more lucrative, more readily collected, or less obnoxious to the caprices of chance, than the impost that was levied in exchange for it, in the shape of a property-tax, extended to the poorest classes:

for now the very soil itself is their surety that paid the tax will be, their means are patent to the light of day, and the superficial extent of their possessions, whatever the weather may chance to be, always remains the same.

Cato, we find, speaks in high praise of garden cabbages: — indeed, it was according to their respective methods of garden cultivation that the agriculturists of early times were appreciated, and it was immediately concluded that it was a sign of a woman being a bad and careless manager of her family, when the kitchen-garden — for this was looked upon as the woman's department more particularly — was negligently cultivated; as in such case her only resource was, of course, the shambles or the herb-market. But cabbages were not held in such high esteem in those days as now: indeed, all dishes were held in disrepute which required something else to help them down, the great object being to economize oil as much as possible; and as to the flesh-market, so much as a wish even to taste its wares was visited with censure and reproach. The chief thing that made them so fond of the garden was the fact that its produce needs no fire and ensures economy in fuel, and that it offers resources which are always ready and at hand. These articles of food, which from their peculiar nature we call “vinegar-diets,” were found to be easy of digestion, by no means apt to blunt and overload the senses, and to create but little craving for bread as an accompaniment. A portion of them which is still used by us for seasonings, attests that our forefathers used only to look at home for their resources, and that no Indian peppers were in request with them, or any of those other condiments which we are in the habit of seeking beyond the seas. In former times the lower classes of Rome, with their mimic gardens in their windows, day after day presented the reflex of the country to the eye, when as yet the multitudes of atrocious burglaries, almost innumerable, had not compelled us to shut out all such sights with bars to the passers by.

Let the garden, then, have its due meed of honour, and let not things, because they are common, enjoy for that the less share of our consideration — and the more so, as we find that from it men of the very highest rank have been content to borrow their surnames even; thus in the Valerian family, for instance, the Lactucini have not thought themselves disgraced by taking their name from the lettuce. Perhaps, too, our labours and research may contribute some slight recommendation to this our subject; although, with Virgil, we are ready to admit how difficult it is, by language however elevated, to ennoble a subject that is so humble in itself.

Detailed table of contents

CHAP. 20.

THE LAYING OUT OF GARDEN GROUND.

There is no doubt that the proper plan is, to have the gardens adjoining the country-house; and they should be watered, more particularly, by a river running in front of it, if possible; or else with water drawn from a well by the aid of a wheel or of pumps, or by swipes. The ground should be opened just as the west winds are beginning to prevail; fourteen days after which it should be got ready for autumn, and then before the winter solstice it should have another turning up. It will require eight men to dig a jugerum, manure being mixed with the earth to a depth of three feet: the ground, too, should be divided into plots or beds with raised and rounded edges, each of which should have a path dug round it, by means of which access may be afforded to the gardener and a channel formed for the water needed for irrigation.

CHAP. 21.

PLANTS OTHER THAN GRAIN AND SHRUBS.

Among the garden plants there are some that recommend themselves by their bulbs, others by the head, others by the stalk, others by the leaf, others by both: some, again, are valued for their seed, others for the outer coat, others for their membranous tissues, others for their cartilaginous substance, others for the firmness of their flesh, and others for the fleshy tunics in which they are enveloped.

Detailed table of contents

CHAP. 22.

THE NATURAL HISTORY OF TWENTY DIFFERENT KINDS OF PLANTS WHICH GROW IN GARDENS — THE PROPER METHODS TO BE FOLLOWED IN SOWING THEM RESPECTIVELY.

Of some plants the fruits are in the earth, of others both in the earth and out of it, and of others, again, out of the earth solely. Some of them increase as they lie upon the ground, gourds and cucumbers, for instance; the same products will grow also in a hanging position, but they are much heavier even then than any of the fruits that grow upon trees. The cucumber, however, is composed of cartilage and a fleshy substance, while the gourd consists of rind and cartilage: this last is the only vegetable production the outer coat of which becomes of a ligneous nature, when ripe. Radishes, turnips, and rape are hidden in the earth, and so, too, are elecampane, skirrets, and parsnips, though in a different manner. There are some plants, again, to which we shall give the name of “ferulaceous,” anise and mallows, for instance; indeed, we find it stated by some writers that in Arabia the mallow becomes arborescent at the sixth month, so much so, in fact, as to admit of its being used for walking-sticks. We have another instance, again, in the mallow-tree of Mauretania, which is found at Lixus, a city built upon an æstuary there; and at which spot, it is said, were formerly the gardens of the Hesperides, at a distance of two hundred paces from the Ocean, near the shrine of Hercules, more ancient, tradition says, than the temple at Gades. This mallow-tree is twenty feet in height, and of such a thickness that there is not a person in existence who is able with his arms to span its girth.

In the class of ferulaceous plants we must include hemp also. There are some plants, again, to which we must give the appellation of “fleshy;” such as those spongy productions which are found growing in damp meadows. As to the fungus, with a hard, tough flesh, we have already made mention of it when speaking of wood and trees; and of truffles, which form another variety, we have but very recently given a description.

Detailed table of contents

CHAP. 23. (5.)

VEGETABLES OF A CARTILAGINOUS NATURE — CUCUMBERS. PEPONES.

The cucumber belongs to the cartilaginous class of plants, and grows above the ground. It was a wonderful favourite with the Emperor Tiberius, and, indeed, he was never without it; for he had raised beds made in frames upon wheels, by means of which the cucumbers were moved and exposed to the full heat of the sun; while, in winter, they were withdrawn, and placed under the protection of frames glazed with mirror-stone. We find it stated, also, by the ancient Greek writers, that the cucumber ought to be propagated from seed that has been steeped a couple of days in milk and honey, this method having the effect of rendering them all the sweeter to the taste. The cucumber, while growing, may be trained to take any form that may be wished: in Italy the cucumbers are green and very small, while those grown in some of the provinces are remarkably large, and of a wax colour or black. Those of Africa, which are also remarkably prolific, are held in high esteem; the same, too, with the cucumbers of Mœesia, which are by far the largest of all. When the cucumber acquires a very considerable volume, it is known to us as the “pepo.” Cucumbers when eaten remain on the stomach till the following day, and are very difficult of digestion; still, for all that, in general they are not considered very unwholesome. By nature they have a wonderful hatred to oil, and no less affection for water, and this after they have been cut from the stem even. If water is within a moderate distance of them, they will creep towards it, while from oil, on the other hand, they will shrink away: if any obstacle, too, should happen to arrest their progress, or if they are left to hang, they will grow curved and crooked. Of these facts we may be satisfactorily convinced in a single night even, for if a vessel filled with water is placed at four fingers’ distance from a cucumber, it will be found to have descended to it by the following morning; but if the same is done with oil, it will have assumed the curved form of a hook by the next day. If hung in a tube while in blossom, the cucumber will grow to a most surprising length. It is only of late, too, that a cucumber of entirely new shape has been produced in Campania, it having just the form of a quince. It was quite by accident, I am told, that the first one acquired this shape in growing, and it was from the seed of this that all the others have been reproduced. The name given to this variety is “melopepo.” These last do not grow hanging, but assume their round shape as they lie on the ground. A thing that is very remarkable in them, in addition to their shape, colour, and smell, is the fact that, when ripe, although they do not hang from the stem, they separate from it at the stalk.

Columella has given us a plan of his, by which we may have cucumbers the whole year round: the largest bramble-bush that can be procured is transplanted to a warm, sunny spot, and then cut down, about the time of the

vernal equinox, to within a couple of fingers of the ground; a cucumber-seed is then inserted in the pith of the bramble, and the roots are well moulded up with fine earth and manure, to withstand the cold. According to the Greeks, there are three kinds of cucumbers, the Laconian, the Scytalic, and the Bœotian, the Laconian being the only one among them that is fond of the water.

There are some persons who recommend steeping the seed of the cucumber in the juice of the herb known as the “culix;” the produce, they say, will be sure to grow without seeds.

Detailed table of contents

CHAP. 24.

GOURDS.

Gourds resemble the cucumber in nature, at least in their manner of growing; they manifest an equal aversion to the winter, too, while they require constant watering and manure. Both cucumbers and gourds are sown in holes a foot and a half deep, between the vernal equinox and the summer solstice, at the time of the Parilia more particularly. Some persons, however, think it better to sow gourds after the calends of March, and cucumbers after the nones, and at the time of the Quinquatria. The cucumber and the gourd climb upwards in a precisely similar manner, their shoots creeping along the rough surface of the walls, even to the very roof, so great is their fondness for elevated spots. They have not sufficient strength, however, to support themselves without the aid of stays. Shooting upwards with the greatest rapidity, they soon cover with their light shade the arched roofs of the houses and the trellises on which they are trained. From this circumstance it is that we find the gourd classified into two primary kinds, the roof-gourd, and the common gourd, which creeps upon the ground. In the first kind, from a stalk of remarkable thinness is suspended a fruit of considerable weight and volume, and quite immoveable by the action of the wind. The gourd, too, as well as the cucumber, admits of being lengthened to any extent, by the aid of osier tubes more particularly. Just after the blossom has fallen off, the plant is introduced into these tubes, and as it grows it can be made to assume any form that may be wished, that of a serpent coiled up being the one that is mostly preferred; if left at liberty to grow as it hangs, it has been known before now to attain to no less than nine feet in length.

The cucumber flowers gradually, blossom succeeding blossom; and it adapts itself perfectly well to a dry soil. It is covered with a white down, which increases in quantity as the plant gains in size.

The gourd admits of being applied to more numerous uses than the cucumber even: the stem is used as an article of food when young, but at a later period it changes its nature, and its qualities become totally different: of late, gourds have come to be used in baths for jugs and pitchers, but for this long time past they have been employed as casks for keeping wine. The rind is tender while the fruit is green, but still it is always scraped off when the gourd is used for food. It admits of being eaten several ways, and forms a light and wholesome aliment, and this although it is one of those fruits that are difficult of digestion by the human stomach, and are apt to swell out those who eat of them. The seeds which lie nearest to the neck of the gourd produce fruit of remarkable length, and so do those which lie at the lower extremities, though not at all comparable with the others. Those, on the other hand, which lie in the middle, produce gourds of a round shape, and those on the sides fruit

that are thick and short. The seeds are dried by being placed in the shade, and when wanted for sowing, are steeped in water first. The longer and thinner the gourd is, the more agreeable it is to the palate, and hence it is that those which have been left to grow hanging are reckoned the most wholesome: these, too, have fewer seeds than the others, the hardness of which is apt to render the fruit less agreeable for eating.

Those which are intended for keeping seed, are usually not cut before the winter sets in; they are then dried in the smoke, and are extensively employed for preserving seeds, and for making other articles for domestic use. There has been a method discovered, also, of preserving the gourd for table, and the cucumber as well, till nearly the time when the next year's crop is ripe; this is done by putting them in brine. We are assured, too, that if put in a hole dug in a place well shaded from the sun, with a layer of sand beneath, and dry hay and earth on the top of them, they may be kept green for a very long time. We also find wild cucumbers and gourds; and, indeed, the same is the case with pretty nearly all the garden plants. These wild varieties, however, are only possessed of certain medicinal properties, and for this reason we shall defer any further mention of them till we come to the Books appropriated to that subject.

Detailed table of contents

CHAP. 25.

RAPE. TURNIPS.

The other plants that are of a cartilaginous nature are concealed, all of them, in the earth. In the number of these is the rape, a subject upon which it would almost appear that we have treated at sufficient length already, were it not that we think it as well to observe, that; medical men call those which are round “male,” while those which are larger and more elongated, are known to them as “female” rape: these last are superior in sweetness, and better for keeping, but by successive sowings they are changed into male rape.

The same authors, too, have distinguished five different varieties of the turnip: the Corinthian, the Cleonæan, the Liothasian, the Bœotian, and the one which they have characterized as peculiarly the “green” turnip. The Corinthian turnip grows to a very large size, and the root is all but out of the ground; indeed, this is the only kind that, in growing, shoots upwards, and not as the others do, downwards into the ground. The Liothasian is known by some persons as the Thracian turnip; it is the one that stands extreme cold the best of all. Next to it, the Bœotian kind is the sweetest; it is remarkable, also, for the roundness of its shape and its shortness; while the Cleonæan turnip, on the other hand, is of an elongated form. Those, in general, which have a thin, smooth leaf, are the sweetest; while those, again, the leaf of which is rough, angular, and prickly, have a pungent taste. There is a kind of wild turnip, also, the leaves of which resemble those of rocket. At Rome, the highest rank is given to the turnips of Amiternum, and those of Nursia; after them, those grown in the neighbourhood of the City are held in the next degree of esteem. The other particulars connected with the sowing of the turnip have been already mentioned by us when speaking of the rape.

Detailed table of contents

CHAP. 26.

RADISHES.

Radishes are composed of an outer coat and a cartilaginous substance, and in many instances the rind is found to be thicker than the bark of some trees. This plant is remarkable for its pungency, which increases in proportion to the thickness of the rind: in some cases, too, the surface of it assumes a ligneous nature. Radishes are flatulent to a remarkable degree, and are productive of eructations; hence it is that they are looked upon as an aliment only fit for low-bred people, and this more particularly if coleworts are eaten directly after them. If, on the other hand, they are eaten with green olives, the eructations produced are not so frequent, and less offensive. In Egypt the radish is held in very high esteem, on account of the abundance of oil that is extracted from the seed. In- deed, the people of that country sow this plant in preference to any other, whenever they can get the opportunity, the profits derived from it being larger than those obtained from the cultivation of corn, and the imposts levied upon it considerably less: there is no grain known that yields a larger quantity of oil.

The Greeks have distinguished the radish into three different kinds, according to the characteristic features of the leaves, there being the crisped leaf, the smooth leaf, and the wild radish, the leaf of which is smooth, but shorter than that of the others; it is round also, grows in great abundance, and spreads like a shrub. The taste of this last variety is acrid, and it acts medicinally as a strong purgative. In the first kind, again, there are certain differences, determined by the seed, for in some varieties the seed is of an inferior quality, and in others remarkably small: these defects, however, are only found to exist in the kind that has the crisped leaf.

Our own people, again, have found other varieties of the radish: there is the Algidan radish, long and transparent, so called from the place of its growth: another, similar to the rape in form, is known as the Syrian radish; it is pretty nearly the mildest and the most tender of them all, and is well able to bear the winter. The very best of all, however, is the one that has been brought from Syria, very recently it would seem, as we do not find it mentioned by any of our writers: it lasts the whole of the winter through. In addition to these kinds, there is another, a wild variety, known by the Greeks as “agrion,” and to the people of Pontus as “armon,” while others, again, call it “leuce, and our people “armoracia;” it has more leaves, however, than root.

In testing the quality of the radish, it is the stem more particularly, that is looked at; in those which are acrid to the taste, for instance, it is rounder and thicker than in the others, and grooved with long channels, while the leaves are more unsightly to the eye, being angular and covered with prickles.

The radish requires to be sown in a loose, humid soil, has a great aversion

to manure, and is content with a dressing solely of chaff: so fond is it of the cold, that in Germany it is known to grow as large as an infant in size. For the spring crop, it is sown immediately after the ides of February; and then again about the time of the Vulcanalia, this last crop being looked upon as the best: many persons, however, sow radishes in March, April, and September. When the plant begins to grow to any size, it is considered a good plan to cover up the leaves successively, and to earth up the root as well; for the part of it which appears above ground is apt to become hard and pithy. Aristomachus recommends the leaves to be taken off in winter, and the roots to be well moulded up, to prevent the water from accumulating about them; and he says, that by using these precautions, they will be all the finer in summer. Some authors have mentioned a plan of making a hole with a dibble, and covering it at the bottom with a layer of chaff, six fingers in depth; upon this layer the seed is put, and then covered over with manure and earth; the result of which is, according to their statement, that radishes are obtained full as large as the hole so made. It is salt, however, that conduces more particularly to their nutriment, and hence it is that they are often watered with brine; in Egypt, too, the growers sprinkle nitre over them, the roots being remarkable for their mildness. The salt, too, has the similar effect of removing all their pungency, and when thus treated, they become very similar in their qualities to radishes that have been boiled: for when boiled they become sweet and mild, and eat, in fact, just like turnips.

Medical men recommend raw radishes to be eaten fasting, with salt, for the purpose of collecting the crude humours of the viscera; and in this way they prepare them for the action of emetics. It is said, too, that the juices of this plant are absolutely necessary for the cure of certain diseases of the diaphragm; for it has been found by experiment, in Egypt, that the phthiriasis which attaches itself to the internal parts of the heart, cannot possibly be eradicated by any other remedy, the kings of that country having ordered the bodies of the dead to be opened and examined, for the purpose of enquiring into certain diseases.

Such, too, is the frivolity of the Greeks, that, in the temple of Apollo at Delphi, it is said, the radish is so greatly preferred to all other articles of diet, as to be represented there in gold, the beet in silver, and the rape in lead. — You might be very sure that Manius Curius was not a native of that country, the general whom, as we find stated in our Annals, the ambassadors of the Samnites found busy roasting rape at the fire, when they came to offer him the gold which he so indignantly refused. Moschion, too, a Greek author, has written a volume on the subject of the radish. These vegetables are considered a very useful article of food during the winter; but they are at all times very injurious to the teeth, as they are apt to wear them away; at all events, they give a polish to ivory. There is a great antipathy between the radish and the vine; which last will shrink from the radish, if sown in its vicinity.

CHAP. 27.

PARSNIPS.

The other kinds which have been classified by us among the cartilaginous plants, are of a more ligneous nature; and it is a singular thing, that they have, all of them, a strong flavour. Among these, there is one kind of wild parsnip which grows spontaneously; by the Greeks it is known as “staphylinos.” Another kind of parsnip is grown either from the root transplanted, or else from seed, at the beginning of spring or in the autumn; Hyginus says that this may be done in February, August, September, and October, the ground being dug to a very considerable depth for the purpose. The parsnip begins to be fit for eating at the end of a year, but it is still better at the end of two: it is reckoned more agreeable eating in autumn, and more particularly if cooked in the saacepan; even then, however, it preserves its strong pungent flavour, which it is found quite impossible to get rid of.

The hibiscum differs from the parsnip in being more slender: it is rejected as a food, but is found useful for its medicinal properties. There is a fourth kind, also, which bears a similar degree of resemblance to the parsnip; by our people it is called the “gallica,” while the Greeks, who have distinguished four varieties of it, give it the name of “daucus.” We shall have further occasion to mention it among the medicinal plants.

Detailed table of contents

CHAP. 28.

THE SKIRRET.

The skirret, too, has had its reputation established by the Emperor Tiberius, who demanded a supply of it every year from Germany. It is at Gelduba, a fortress situate on the banks of the Rhenus, that the finest are grown; from which it would appear that they thrive best in a cold climate. There is a string running through the whole length of the skirret, and which is drawn out after it is boiled; but still, for all this, a considerable proportion of its natural pungency is retained; indeed, when modified by the addition of honied wine, this is even thought to impart to dishes an additional relish. The larger parsnip has also a similar sting inside, but only when it is a year old. The proper time for sowing the skirret is in the months of February, March, April, August, September, and October.

Detailed table of contents

CHAP. 29.

ELECAMPANE.

Elecampane is not so elongated as the preceding roots, but more substantial and more pungent; eaten by itself it is very injurious to the stomach, but when mixed with other condiments of a sweet nature, it is extremely wholesome. There are several methods employed for modifying its natural acidity and rendering it agreeable to the palate: thus, for instance, when dried it is reduced to a fine flour, and then mixed with some sweet liquid or other, or else it is boiled in vinegar and water, or kept in soak in it; it is also steeped in various other ways, and then mixed with boiled grape-juice, or else incorporated with honey or raisins, or dates with plenty of meat on them. Other persons, again, have a method of preparing it with quinces, or else sorbs or plums, while sometimes the flavour is varied by the addition of pepper or thyme.

This plant is particularly good for weakness of the stomach, and it has acquired a high reputation from the circumstance that Julia Augusta used to eat it daily. The seed of it is quite useless, as the plant is reproduced, like the reed, from eyes extracted from the root. This vegetable, as well as the skirret and the parsnip, is sown both in spring and autumn, a considerable distance being left between the plants; indeed, for elecampane, a space of no less than three feet is required, as it throws out its shoots to a very considerable distance. Skirrets, however, are best transplanted.

[Detailed table of contents](#)

CHAP. 30.

BULBS, SQUILLS, AND ARUM.

Next in affinity to these plants are the bulbs, which Cato, speaking in high terms of those of Megara, recommends most particularly for cultivation. Among these bulbs, the squill, we find, occupies the very highest rank, although by nature it is medicinal, and is employed for imparting an additional sharpness to vinegar: indeed, there is no bulb known that grows to a larger size than this, or is possessed of a greater degree of pungency. There are two varieties of it employed in medicine, the male squill, which has white leaves, and the female squill, with black ones. There is a third kind also, which is good to eat, and is known as the Epimenidian squill; the leaf is narrower than in the other kinds, and not so rough. All the squills have numerous seeds, but they come up much more quickly if propagated from the offsets that grow on the sides. To make them attain a still greater size, the large leaves that grow around them are turned down and covered over with earth; by which method all the juices are carried to the heads. Squills grow spontaneously and in vast numbers in the Baleares and the island of Ebusus, and in the Spanish provinces. The philosopher Pythagoras has written a whole volume on the merits of this plant, setting forth its various medicinal properties; of which we shall have occasion to speak more at length in the succeeding Book.

The other species of bulbs are distinguished by their colour, size, and sweetness; indeed, there are some that are eaten raw even — those found in the Tauric Chersonesus, for instance. Next to these, the bulbs of Africa are held in the highest esteem, and after them those of Apulia. The Greeks have distinguished the following varieties: the bulbine, the seta-nion, the opition, the cyix, the leucoion, the ægilips, and the sisyrinchion — in the last there is this remarkable feature, that the extremities of the roots increase in winter, but during the spring, when the violet appears, they diminish in size and gradually contract, and then it is that the bulb begins to increase in magnitude. Among the varieties of the bulb, too, there is the plant known in Egypt by the name of “aron.” In size it is very nearly as large as the squill, with a leaf like that of lapathum, and a straight stalk a couple of cubits in length, and the thickness of a walking-stick: the root of it is of a milder nature, so much so, indeed, as to admit of being eaten raw.

Bulbs are taken up before the spring, for if not, they are apt to spoil very quickly. It is a sign that they are ripe when the leaves become dry at the lower extremities. When too old they are held in disesteem; the same, too, with the long and the smaller ones; those, on the other hand, which are red and round are greatly preferred, as also those of the largest size. In most of them there is a certain degree of pungency in the upper part, but the middle is sweet. The

ancients have stated that bulbs are reproduced from seed only, but in the champaign country of Præneste they grow spontaneously, and they grow to an unlimited extent in the territory of the Remi.

Detailed table of contents

CHAP. 31. (6.)

THE ROOTS, FLOWERS, AND LEAVES OF ALL THESE PLANTS. GARDEN PLANTS WHICH LOSE THEIR LEAVES.

Nearly all the garden plants have a single root only, radishes, beet, parsley, and mallows, for example; it is lapathum, however, that has the longest root of them all, it attaining the length of three cubits even. The root of the wild kind is smaller and of a humid nature, and when up it will keep alive for a considerable period. In some of these plants, however, the roots are fibrous, as we find the case in parsley and mallows, for instance; in others, again, they are of a ligneous nature, as in ocimum, for example; and in others they are fleshy, as in beet, and in saffron even more so. In some, again, the root is composed of rind and flesh, as in the radish and the rape; while in others it is jointed, as in hay grass. Those plants which have not a straight root throw out immediately a great number of hairy fibres, orange and blite, for instance: squills again, bulbs, onions, and garlic never have any but a vertical root. Among the plants that grow spontaneously, there are some which have more numerous roots than leaves, spalax, for example, pellitory, and saffron.

Wild thyme, southernwood, turnips, radishes, mint, and rue blossom all at once; while others, again, shed their blossom directly they have begun to flower. Ocimum blossoms gradually, beginning at the lower parts, and hence it is that it is so very long in blossom: the same is the case, too, with the plant known as heliotropium. In some plants the flower is white, in others yellow, and in others purple. The leaves fall first from the upper part in wild-marjoram and elecampane, and in rue sometimes, when it has been injured accidentally. In some plants the leaves are hollow, the onion and the scallion, more particularly.

Detailed table of contents

CHAP. 32.

VARIETIES OF THE ONION.

Garlic and onions are invoked by the Egyptians, when taking an oath, in the number of their deities. The Greeks have many varieties of the onion, the Sardinian onion, the Samothracian, the Alsidenian, the setanian, the schistan, and the Ascalonian, so called from Ascalon, a city of Judæa. They have, all of them, a pungent smell, which draws tears from the eyes, those of Cyprus more particularly, and those of Cnidos the least of all. In all of them the body is composed of a cartilage of an unctuous nature. The variety known as the setanian is the smallest of them all, with the exception of the Tusculan onion, but it is sweet to the taste. The schistan and the Ascalonian kinds are used for storing. The schistan onion is left during the winter with the leaves on; in the spring it is stripped of them, upon which offsets make their appearance at the same divisions as the leaves; it is to this circumstance that this variety owes its name. Taking the hint from this fact, it is recommended to strip the other kinds of their leaves, to make them bulb all the better, instead of running to seed.

The Ascalonian onion is of a peculiar nature, being barren in some measure in the root; hence it is that the Greeks have recommended it to be reproduced from seed, and not from roots: the transplanting, too, they say, should be done later in the spring, at the time the plant germinates, the result being that it bulbs with all the greater rapidity, and hastens, as it were, to make up for lost time; great dispatch, however, is requisite in taking it up, for when ripe it rots with the greatest rapidity. If propagated from roots, it throws out a long stalk, runs rapidly to seed, and dies.

There are considerable differences, too, in the colour of the onion; the whitest of all are those grown at Issus and Sardes. The onions, too, of Crete are held in high esteem, but there is some doubt whether they are not the same as the Ascalonian variety; for when grown from seed they produce a fine bulb, but when planted they throw out a long stalk and run to seed; in fact, they differ from the Ascalonian kind only in the sweetness of their flavour.

Among us there are two principal varieties known of the onion; the scallion, employed for seasonings, is one, known to the Greeks by the name of “gethyon,” and by us as the “pallacana;” it is sown in March, April, and May. The other kind is the bulbed or headed onion; it is sown just after the autumnal equinox, or else after the west winds have begun to prevail. The varieties of this last kind, ranged according to their relative degrees of pungency, are the African onion, the Gallic, the Tusculan, the Ascalonian, and the Amiternian: the roundest in shape are the best. The red onion, too, is more pungent than the white, the stored than the fresh, the raw than the cooked, and the dried than the preserved. The onion of Amiternum is cultivated in cold,

humid localities, and is the only one that is reproduced from heads, like garlic, the other kinds being grown from seed. This last kind yields no seed in the ensuing summer, but a bulb only, which dries and keeps; but in the summer after, the contrary is the case, for seed is produced, while the bulb very quickly spoils. Hence it is that every year there are two separate sowings, one of seed for the reproduction of bulbs, and one of bulbs for the growth of seed; these onions keep best in chaff. The scallion has hardly any bulb at all, but a long neck only — hence it is nothing but leaf, and is often cut down, like the leek; for this reason, too, like the leek, it is grown from seed, and not from plants.

In addition to these particulars, it is recommended that the ground intended for sowing onions should be turned up three times, care being taken to remove all roots and weeds; ten pounds of seed is the proper proportion for a jugerum. Savory too, they say, should be mixed with them, the onions being all the finer for it; the ground, too, should be stubbed and hoed four times at least, if not oftener. In Italy, the Ascalonian onion is sown in the month of February. The seed of the onion is gathered when it begins to turn black, and before it becomes dry and shrivelled.

Detailed table of contents

CHAP. 33.

THE LEEK.

While upon this subject, it will be as well, too, to speak of the leek, on account of the affinity which it bears to the plants just mentioned, and more particularly because cut-leek has recently acquired considerable celebrity from the use made of it by the Emperor Nero. That prince, to improve his voice, used to eat leeks and oil every month, upon stated days, abstaining from every other kind of food, and not touching so much as a morsel of bread even. Leeks are reproduced from seed, sown just after the autumnal equinox; if they are intended for cutting, the seed is sown thicker than otherwise. The leeks in the same bed are cut repeatedly, till it is quite exhausted, and they are always kept well manured. If they are wanted to bulb before being cut, when they have grown to some size they are transplanted to another bed, the extremities of the leaves being snapped off without touching the white part, and the heads stripped of the outer coats. The ancients were in the habit of placing a stone or potsherd upon the leek, to make the head grow all the larger, and the same with the bulbs as well; but at the present day it is the usual practice to move the fibrous roots gently with the weeding-hook, so that by being bent they may nourish the plant, and not withdraw the juices from it.

It is a remarkable fact, that, though the leek stands in need of manure and a rich soil, it has a particular aversion to water; and yet its nature depends very much upon the natural properties of the soil. The most esteemed leeks are those grown in Egypt, and next to them those of Ostia and Aricia. Of the leek for cutting, there are two varieties: that with grass-green leaves and incisions distinctly traced on them, and the leek with paler and rounder leaves, the incisions being more lightly marked. There is a story told, that Mela, a member of the Equestrian order, being accused of mal-administration by order of the Emperor Tiberius, swallowed in his despair leek-juice to the amount of three denarii in weight of silver, and expired upon the spot without the slightest symptom of pain. It is said, however, that a larger dose than this is productive of no injurious effects whatever.

Detailed table of contents

CHAP. 34

GARLIC.

Garlic is generally supposed, in the country more particularly, to be a good specific for numerous maladies. The external coat consists of membranes of remarkable fineness, which are universally discarded when the vegetable is used; the inner part being formed by the union of several cloves, each of which has also a separate coat of its own. The flavour of it is pungent, and the more numerous the cloves the more pungent it is. Like the onion, it imparts an offensive smell to the breath; but this is not the case when it is cooked. The various species of garlic are distinguished by the periods at which they ripen: the early kind becomes fit for use in sixty days. Another distinction, too, is formed by the relative size of the heads. Ulpicum, also, generally known to the Greeks as "Cyprian garlic," belongs to this class; by some persons it is called "antiscorodon," and in Africa more particularly it holds a high rank among the dishes of the rural population; it is of a larger size than ordinary garlic. When beaten up with oil and vinegar, it is quite surprising what a quantity of creaming foam is produced.

There are some persons who recommend that neither ulpikum nor garlic should be sown on level ground, but say that they should be planted in little mounds trenched up, at a distance of three feet apart. Between each clove, they say, there should be a distance of four fingers left, and as soon as ever three leaves are visible, the heads should be hoed; the oftener they are hoed, the larger the size they will attain. When they begin to ripen, the stalks are bent downwards, and covered over with earth, a precaution which effectually prevents them from running to leaf. In cold soils, it is considered better to plant them in spring than in autumn.

For the purpose of depriving all these plants of their strong smell, it is recommended to set them when the moon is below the horizon, and to take them up when she is in conjunction. Independently of these precautions, we find Menander, one of the Greek writers, recommending those who have been eating garlic to eat immediately afterwards a root of beet roasted on hot coals; if this is done, he says, the strong smell of the garlic will be effectually neutralized. Some persons are of opinion, that the proper period for planting garlic and ulpikum is between the festival of the Compitalia and that of the Saturnalia. Garlic, too, can be grown from seed, but it is very slow, in such case, in coming to maturity; for in the first year, the head attains the size only of that of a leek, in the second, it separates into cloves, and only in the third it arrives at maturity; there are some, however, who think that garlic grown this way is the best. Garlic should never be allowed to run to seed, but the stalk should be twisted, to promote its growth, and to make the head attain a larger size.

If garlic or onions are wanted to keep some time, the heads should be dipped in salt water, made luke-warm; by doing this, they will be all the better for keeping, though quite worthless for reproduction. Some persons content themselves with hanging them over burning coals, and are of opinion that this is quite sufficient to prevent them from sprouting: for it is a well-known fact, that both garlic and onions sprout when out of the ground, and that after throwing out their thin shoots they shrivel away to nothing. Some persons are of opinion, too, that the best way of keeping garlic is by storing it in chaff. There is a kind of garlic that grows spontaneously in the fields, and is known by the name of “alum.” To preserve the seeds that are sown there from the remorseless ravages of the birds, this plant is scattered over the ground, being first boiled, to prevent it from shooting. As soon as ever they have eaten of it, the birds become so stupefied as to be taken with the hand even, and if they remain but a few moments only on the spot, they fall fast asleep. There is a wild garlic, too, generally known as “bear’s” garlic; it has exactly the smell of millet, with a very small head and large leaves.

CHAP. 35. (7.)

THE NUMBER OF DAYS REQUIRED FOR THE RE- SPECTIVE PLANTS TO MAKE THEIR APPEARANCE ABOVE GROUND.

Among the garden plants which make their appearance most speedily above ground, are ocimum, blite, the turnip, and rocket; for they appear above the surface the third day after they are sown. Anise, again, comes up on the fourth day, the lettuce on the fifth, the radish on the sixth, the cucumber and the gourd on the seventh — the cucumber rather the first of the two — cresses and mustard on the fifth, beet on the sixth day in summer and the tenth in winter, orage on the eighth, onions on the nineteenth or twentieth, and scallions on the tenth or twelfth. Coriander, again, is more stubborn in its growth, cunila and wild marjoram do not appear till after the thirtieth day, and parsley comes up with the greatest difficulty of all, for at the very earliest it is forty days before it shows itself, and in most instances as much as fifty.

The age, too, of the seed is of some importance in this respect; for fresh seed comes up more rapidly in the case of the leek, the scallion, the cucumber, and the gourd, while in that of parsley, beet, cardamum, cunila, wild majoram, and coriander, seed that has been kept for some time is the best.

There is one remarkable circumstance in connection with the seed of beet; it does not all germinate in the first year, but some of it in the second, and some in the third even; hence it is that a considerable quantity of seed produces only a very moderate crop. Some plants produce only in the year in which they are set, and some, again, for successive years, parsley, leeks, and scallions for instance; indeed, these plants, when once sown, retain their fertility, and produce for many years.

Detailed table of contents

CHAP. 36.

THE NATURE OF THE VARIOUS SEEDS.

In most plants the seed is round, in some oblong; it is broad and foliaceous in some, orage for instance, while in others it is narrow and grooved, as in cummin. There are differences, also, in the colour of seeds, which is either black or white; while some seeds are woody and hard, in radishes, mustard, and rape, the seeds are enclosed in pods. In parsley, coriander, anise, fennel, and cummin, the seed has no covering at all, while in blite, beet, orage, and ocimum, it has an outer coat, and in the lettuce it is covered with a fine down. There is no seed more prolific than that of ocimum; it is generally recommended to sow it with the utterance of curses and imprecations, the result being that it grows all the better for it; the earth, too, is rammed down when it is sown, and prayers offered that the seed may never come up. The seeds which are enveloped in an outer coat, are dried with considerable difficulty, that of ocimum more particularly; hence it is that all these seeds are dried artificially, their fruitfulness being greatly promoted thereby.

Plants in general come up better when the seed is sown in heaps than when it is scattered broad-cast: leeks, in fact, and parsley are generally grown by sowing the seed in little bags: in the case of parsley, too, a hole is made with the dibble, and a layer of manure inserted.

All garden plants grow either from seed or from slips, and some from both seed and suckers, such as rue, wild marjoram, and ocimum, for example — this last being usually cut when it is a palm in height. Some kinds, again, are reproduced from both seed and root, as in the case of onions, garlic, and bulbs, and those other plants of which, though annuals themselves, the roots retain their vitality. In those plants which grow from the root, it lives for a considerable time, and throws out offsets, as in bulbs, scallions, and squills for example. — Others, again, throw out offsets, though not from a bulbous root, such as parsley and beet, for instance. When the stalk is cut, with the exception of those which have not a rough stem, nearly all these plants put forth fresh shoots, a thing that may be seen in ocimum, the radish, and the lettuce, which are in daily use among us; indeed, it is generally thought that the lettuce which is grown from a fresh sprouting, is the sweetest. The radish, too, is more pleasant eating when the leaves have been removed before it has begun to run to stalk. The same is the case, too, with rape; for when the leaves are taken off, and the roots well covered up with earth, it grows all the larger for it, and keeps in good preservation till the ensuing summer.

CHAP. 37.

PLANTS OF WHICH THERE IS BUT A SINGLE KIND PLANTS OF WHICH THERE
ARE SEVERAL KINDS.

Of ocimum, lapathum, blite, cresses, rocket, orage, coriander, and anise respectively, there is but a single kind, these plants being the same everywhere, and no better in one place than in another. It is the general belief that stolen rue grows the best, while, on the other hand, bees that have been stolen will never thrive. Wild mint, cat-mint, endive, and pennyroyal, will grow even without any cultivation. With reference to the plants of which we have already spoken, or shall have occasion to speak, there are numerous varieties of many of them, parsley more particularly.

(8.) As to the kind of parsley which grows spontaneously in moist localities, it is known by the name of “helioselinum;” it has a single leaf only, and is not rough at the edges. In dry places, we find growing the kind known as “hipposelinum,” consisting of numerous leaves, similar to helioselinum. A third variety is the oreoselinum, with leaves like those of hemlock, and a thin, fine, root, the seed being similar to that of anise, only somewhat smaller.

The differences, again, that are found to exist in cultivated parsley, consist in the comparative density of the leaves, the crispness or smoothness of their edges, and the thinness or thickness of the stem, as the case may be: in some kinds, again, the stem is white, in others purple, and in others mottled.

CHAP. 38.

THE NATURE AND VARIETIES OF TWENTY-THREE GARDEN PLANTS. THE LETTUCE; ITS DIFFERENT VARIETIES.

The Greeks have distinguished three varieties of the lettuce; the first with a stalk so large, that small garden gates, it is said, have been made of it: the leaf of this lettuce is somewhat larger than that of the herbaceous, or green lettuce, but extremely narrow, the nutriment seeming to be expended on the other parts of the plant. The second kind is that with a rounded stalk; and the third is the low, squat lettuce generally known as the Laconian lettuce.

Some persons have made distinctions in reference to their respective colours, and the times for sowing them: the black lettuce is sown in the month of January, the white in March, and the red in April; and they are fit for transplanting, all of them, at the end of a couple of months. Those, again, who have pursued these enquiries even further than this, have distinguished a still greater number of varieties of them — the purple, the crisped, the Cappadocian, and the Greek lettuce, this last having a longer leaf than the rest, and a broad stalk: in addition to which, there is one with a long, narrow leaf, very similar to endive in appearance. The most inferior kind, however, of all, is the one to which the Greeks, censuring it for its bitterness, have given the name of “picris.” There is still another variety, a kind of white lettuce, called “meconis,” a name which it derives from the abundance of milk, of a narcotic quality, which it produces; though, in fact, it is generally thought that they are all of them of a soporific tendency. In former times, this last was the only kind of lettuce that was held in any esteem in Italy, the name “lactuca” having been given it on account of the milk which it contains.

The purple kind, with a very large root, is generally known as the Cæcilian lettuce; while the round one, with an extremely diminutive root and broad leaves, is known to some persons as the “astytis,” and to others as the “eunychion,” it having the effect, in a remarkable degree, of quenching the amorous propensities. Indeed, they are, all of them, possessed of cooling and refreshing properties, for which reason it is, that they are so highly esteemed in summer; they have the effect, also, of removing from the stomach distaste for food, and of promoting the appetite. At all events, we find it stated, that the late Emperor Augustus, when ill, was saved on one occasion, thanks to the skill of his physician, Musa, by eating lettuces, a food which the excessive scruples of his former physician, C. Æmilius, had forbidden him. At the present day, however, lettuces have risen into such high estimation, that a method has been discovered even of preserving them during the months in which they are out of season, by keeping them in oxymel. It is generally supposed, also, that lettuces have the effect of making blood.

In addition to the above varieties, there is another kind of lettuce known as the “goats’ lettuce,” of which we shall have occasion to make further mention

when we come to the medicinal plants: at the moment, too, that I am writing this, a new species of cultivated lettuce has been introduced, known as the Cilician lettuce, and held in very considerable esteem; the leaf of it is similar to that of the Cappadocian lettuce, except that it is crisped, and somewhat larger.

Detailed table of contents

CHAP. 39.

ENDIVE.

Endive, though it cannot exactly be said to be of the same genus as the lettuce, still cannot be pronounced to belong to any other. It is a plant better able to endure the rigours of the winter than the lettuce, and possessed of a more acrid taste, though the flavour of the stalk is equally agreeable. Endive is sown at the beginning of spring, and transplanted at the end of that season. There is also a kind of spreading endive, known in Egypt as “cichorium,” of which we shall have occasion to speak elsewhere more at length.

A method has been discovered of preserving all the thyrsi or leaves of the lettuce in pots, the object being to have them fresh when wanted for boiling. Lettuces may be sown all the year through in a good soil, well-watered and carefully manured; two months being allowed to intervene between sowing and transplanting, and two more between transplanting and gathering them when ripe. The rule is, however, to sow them just after the winter solstice, and to transplant when the west winds begin to prevail, or else to sow at this latter period, and to plant out at the vernal equinox. The white lettuce is the best adapted for standing the rigours of the winter.

All the garden plants are fond of moisture; lettuces thrive, more particularly, when well manured, and endive even more so. Indeed, it is found an excellent plan to plant them out with the roots covered up in manure, and to keep up the supply, the earth being cleared away for that purpose. Some, again, have another method of increasing their size; they cut them down when they have reached half a foot in height, and cover them with fresh swine’s dung. It is the general opinion that those lettuces only will admit of being blanched which are produced from white seed; and even then, as soon as they begin to grow, sand from the sea-shore should be spread over them, care being taken to tie the leaves as soon as ever they begin to come to any size.

Detailed table of contents

CHAP. 40.

BEET: FOUR VARIETIES OF IT.

Beet is the smoothest of all the garden plants. The Greeks distinguish two kinds of beet, according to the colour, the black and the white. The last, which is the kind generally preferred, has but very little seed, and is generally known as the Sicilian beet; just as it is the white lettuce that is held in the highest degree of esteem. Our people, also, distinguish two varieties of beet, the spring and the autumn kinds, so called from the periods of sowing; although sometimes we find beet sown in June even. This is a plant, too, that is sometimes transplanted; and it thrives all the better, like the lettuce, if the roots are well covered with manure, in a moist soil. Beet is mostly eaten with lentils and beans; it is prepared also in the same way as cabbage, with mustard more particularly, the pungency of which relieves its insipidity. Medical men are of opinion that beet is a more unwholesome vegetable than cabbage; hence it is that I never remember seeing it served at table. Indeed, there are some persons who scruple to taste it even, from a conviction that it is a food suitable only for persons of a robust constitution.

Beet is a vegetable with twofold characteristics, partaking of the nature of the cabbage in its leaves and resembling a bulb in the root; that which grows to the greatest breadth being the most highly esteemed. This plant, like the lettuce, is made to grow to head by putting a light weight upon it the moment it begins to assume its proper colour. Indeed, there is no garden plant that grows to a larger head than this, as it sometimes spreads to a couple of feet in breadth, the nature of the soil contributing in a very considerable degree to its size: those found in the territory of Circeii attain the largest size. Some persons think that the best time for sowing beet is when the pomegranate is in flower, and are of opinion that it ought to be transplanted as soon as it has thrown out five leaves. There is a singular difference — if indeed it really exists — between the two varieties of beet, the white kind being remarkable for its purgative qualities, and the black being equally astringent. When wine in the vat has been deteriorated by assuming a flavour like that of cabbage, its original flavour is restored, it is said, by plunging beet leaves into it.

Detailed table of contents

CHAP. 41

CABBAGES; THE SEVERAL VARIETIES OF THEM.

Cabbage and coleworts, which at the present day are the most highly esteemed of all the garden vegetables, were held in little repute, I find, among the Greeks; but Cato, on the other hand, sings the wondrous praises of the cabbage, the medicinal properties of which we shall duly enlarge upon when we come to treat of that subject. Cato distinguishes three varieties of the cabbage; the first, a plant with leaves wide open, and a large stalk; a second, with crisped leaves, to which he gives the name of “apiaca;” and a third, with a thin stalk, and a smooth, tender leaf, which with him ranks the lowest of all. Cabbages may be sown the whole year through, as we find that they are cut at all periods of the year; the best time, however, for sowing them is at the autumnal equinox, and they are usually transplanted as soon as five leaves are visible. In the ensuing spring after the first cutting, the plant yields sprouts, known to us as “cymæ.” These sprouts, in fact, are small shoots thrown out from the main stem, of a more delicate and tender quality than the cabbage itself. The exquisite palate, however, of Apicius rejected these sprouts for the table, and his example was followed by the fastidious Drusus Cæsar; who did not escape, however, the censures of his father, Tiberius, for being so over-nice. After the cymæ have made their appearance the cabbage throws out its summer and autumn shoots, and then its winter ones; after which, a new crop of cymæ is produced, there being no plant so productive as this, until, at last, it is quite exhausted by its extreme fertility. A second time for sowing cabbages is immediately after the vernal equinox, the plants of this growth being transplanted at the end of spring, that they may not run up into sprouts before coming to a top: and a third sowing takes place about the summer solstice, the transplanting being done in summer if the soil is moist, but, if too dry, in autumn. When moisture and manure are supplied in small quantities, the flavour of the cabbage is all the more agreeable, but when they are supplied in greater abundance, the plants attain a larger size. Asses’ dung is the best adapted for its growth.

The cabbage, too, is one of those articles so highly esteemed by epicures; for which reason it will not be amiss if we speak of it at somewhat greater length. To obtain plants equally remarkable for their size and flavour, care must be taken first of all to sow the seed in ground that has had a couple of turnings up, and then to follow up the shoots as they appear above ground by moulding them up, care being taken to throw up the earth over them as they increase in luxuriance, and to let nothing but the summit appear above the surface. This kind is known as the Tritian cabbage: in money and labour it costs twice as much as any of the others.

The other varieties of the cabbage are numerous — there is the Cumanian

cabbage, with leaves that lie close to the ground, and a wide, open head; the Aricinian cabbage, too, of no greater height, but with more numerous leaves and thinner — this last is looked upon as the most useful of them all, for beneath nearly all of the leaves there are small shoots thrown out, peculiar to this variety. The cabbage, again, of Pompeii is considerably taller, the stalk, which is thin at the root, increasing in thickness as it rises among the leaves, which are fewer in number and narrower; the great merit of this cabbage is its remarkable tenderness, although it is not able to stand the cold. The cabbage of Bruttium, on the other hand, thrives all the better for cold; the leaves of it are remarkably large, the stalk thin, and the flavour pungent. The leaves, again, of the Sabine cabbage are crisped to such a degree as to excite our surprise, and their thickness is such as to quite exhaust the stem; in sweetness, however, it is said to surpass all the others.

There have lately come into fashion the cabbages known as the “Lacuturres;” they are grown in the valley of Aricia, where there was formerly a lake, now no longer in existence, and a tower which is still standing. The head of this cabbage is very large, and the leaves are almost without number, some of them being round and smooth, and others long and sinewy; indeed, there is no cabbage that runs to a larger head than this, with the sole exception of the Tritian variety, which has a head sometimes as much as a foot in thickness, and throws out its cymæ the latest of all.

In all kinds of cabbages, hoar-frost contributes very materially to their sweetness; but it is apt to be productive of considerable injury, if care is not taken to protect the pith by cutting them aslant. Those plants which are intended for seed are never cut.

There is another kind, again, that is held in peculiar esteem, and which never exceeds the height of an herbaceous plant; it is known by the name of “halmyridia,” from the circumstance of its growing on the sea-shore only. It will keep green and fresh during a long voyage even, if care is taken not to let it touch the ground from the moment that it is cut, but to put it into oil-vessels lately dried, and then to bung them so as to effectually exclude all air. There are some who are of opinion, that the plant will come to maturity all the sooner if some sea-weed is laid at the root when it is transplanted, or else as much pounded nitre as can be taken up with three fingers; and others, again, sprinkle the leaves with trefoil seed and nitre pounded together. Nitre, too, preserves the greenness of cabbage when cooked, a result which is equally ensured by the Apician mode of boiling, or in other words, by steeping the plants in oil and salt before they are cooked.

There is a method of grafting vegetables by cutting the shoots and the stalk, and then inserting in the pith the seed of another plant; a plan which has been adopted with the wild cucumber even. There is another kind of wild cabbage, also, the lapsana, which has become famous since the triumphs of the late Emperor Julius, in consequence of the songs and jokes of his soldiers more particularly; for in the alternate lines sung by them, they used to

reproach him for having made them live on lapsana at the siege of Dyrrhachium, and to rally him upon the parsimonious scale on which he was in the habit of recompensing their services. The lapsana is nothing more than a wild cyma.

Detailed table of contents

CHAP. 42.

WILD AND CULTIVATED ASPARAGUS.

Of all the garden plants, asparagus is the one that requires the most delicate attention in its cultivation. We have already spoken at considerable length of its origin, when treating of the wild plants, and have mentioned that Cato recommends it to be grown in reed-beds. There is another kind, again, of a more uncultivated nature than the garden asparagus, but less pungent than *corruda*; it grows upon the mountains in different countries, and the plains of Upper Germany are quite full of it, so much so, indeed, that it was a not unhappy remark of Tiberius Cæsar, that a weed grows there which bears a remarkably strong resemblance to asparagus. That which grows spontaneously upon the island of Nesis, off the coast of Campania, is looked upon as being by far the best of all.

Garden asparagus is reproduced from roots, the fibres of which are exceedingly numerous, and penetrate to a considerable depth. When it first puts forth its shoots, it is green; these in time lengthen out into stalks, which afterwards throw out streaked branches from the head: asparagus admits, also, of being grown from seed.

Cato has treated of no subject with greater care than this, the last Chapter of his work being devoted to it, from which we may conclude that it was quite new to him, and a subject which had only very recently occupied his attention. He recommends that the ground prepared for it should be a moist or dense soil, the seed being set at intervals of half a foot every way, to avoid treading upon the heads; the seed, he says, should be put two or three into each hole, these being made with the dibble as the line runs — for in his day, it should be remembered, asparagus was only grown from seed — this being done about the vernal equinox. It requires, he adds, to be abundantly manured, and to be kept well hoed, due care being taken not to pull up the young plants along with the weeds. The first year, he says, the plants must be protected from the severity of the winter with a covering of straw, care being taken to uncover them in the spring, and to hoe and stub up the ground about them. In the spring of the third year, the plants must be set fire to, and the earlier the period at which the fire is applied, the better they will thrive. Hence it is, that as reed-beds grow all the more rapidly after being fired, asparagus is found to be a crop remarkably well suited for growing with them. The same author recommends, however, that asparagus should not be hoed before the plants have made their appearance above-ground, for fear of disturbing the roots; and he says that in gathering the heads, they should be cut close to the root, and not broken off at the surface, a method which is sure to make them run to stalk and die. They should be cut, he says, until they are left to run to seed, and after the seed is ripe, in spring they must be fired, care being taken, as

soon as they appear again, to hoe and manure them as before. After eight or nine years, he says, when the plants have become old, they must be renewed, after digging and manuring the ground, by replanting the roots at intervals of a foot, care being taken to employ sheep's dung more particularly for the purpose, other kinds of manure being apt to produce weeds.

No method of cultivating this plant that has since been tried has been found more eligible than this, with the sole exception that the seed is now sown about the ides of February, by laying it in heaps in small trenches, after steeping it a considerable time in manure; the result of which is that the roots become matted, and form into spongy tufts, which are planted out at intervals of a foot after the autumnal equinox, the plants continuing to be productive so long as ten years even. There is no soil more favourable to the growth of asparagus, than that of the gardens of Ravenna.

We have already spoken of the corruda, by which term I mean the wild asparagus, by the Greeks called "orminos," or "myacanthos," as well as by other names. I find it stated, that if rams' horns are pounded, and then buried in the ground, asparagus will come up.

Detailed table of contents

CHAP. 43.

THISTLES.

It really might have been thought that I had now given an account of all the vegetable productions that are held in any degree of esteem, did there not still remain one plant, the cultivation of which is extremely profitable, and of which I am unable to speak without a certain degree of shame. For it is a well-known fact, that some small plots of land, planted with thistles, in the vicinity of Great Carthage and of Corduba more particularly, produce a yearly income of six thousand sesterces; this being the way in which we make the monstrous productions even of the earth subservient to our gluttonous appetites, and that, too, when the very four-footed brutes instinctively refuse to touch them.

Thistles are grown two different ways, from plants set in autumn, and from seed sown before the nones of March; in which latter case they are transplanted before the ides of November, or, where the site is a cold one, about the time that the west winds prevail. They are sometimes manured even, and if such is the will of heaven, grow all the better for it. They are preserved, too, in a mixture of honey and vinegar, with the addition of root of laser and cummin — so that a day may not pass without our having thistles at table.

Detailed table of contents

CHAP. 44.

OTHER PLANTS THAT ARE SOWN IN THE GARDEN: OCIMUM; ROCKET; AND NASTURTIIUM.

For the remaining plants a brief description will suffice. The best time for sowing ocimum, it is said, is at the festival of the Parilia; though some say that it may be done in autumn as well, and recommend, when it is sown in winter, to drench the seed thoroughly with vinegar. Rocket, too, and nasturtium may be grown with the greatest facility either in summer or winter. Rocket, more particularly, is able to stand the cold, and its properties are quite different from those of the lettuce, as it is a great provocative of lust. Hence it is that we are in the habit of mixing these two plants in our dishes, the excess of cold in the one being compensated by the equal degree of heat in the other. Nasturtium has received that name from the smarting sensation which its pungency causes to the nostrils, and hence it is that a certain notion of smartness has attached itself to the word, it having become quite a proverbial saying, that a sluggish man should eat nasturtium, to arouse him from his torpidity. In Arabia, it is said, this plant attains a size that is quite marvellous.

Detailed table of contents

CHAP. 45.

RUE.

Rue, too, is generally sown while the west winds prevail, as well as just after the autumnal equinox. This plant has an extreme aversion to cold, moisture, and dung; it loves dry, sunny localities, and a soil more particularly that is rich in brick clay; it requires to be nourished, too, with ashes, which should be mixed with the seed as well, as a preservative against the attacks of caterpillars. The ancients held rue in peculiar esteem; for I find that honied wine flavoured with rue was distributed to the people, in his consulship, by Cornelius Cethegus, the colleague of Quintus Flaminius, after the closing of the Comitia. This plant has a great liking for the fig-tree, and for that tree only; indeed, it never thrives better than when grown beneath that tree. It is generally grown from slips, the lower end of which is inserted in a perforated bean, which holds it fast, and so nurtures the young plant with its juices. It also reproduces itself; for the ends of the branches bending downwards, the moment they reach the ground, they take root again. Ocimum is of a very similar nature to rue, except that it dries with greater difficulty. When rue has once gained strength, there is considerable difficulty in stubbing it, as it causes itching ulcerations on the hands, if they are not covered or previously protected by being rubbed with oil. Its leaves, too, are preserved, being packed in bundles for keeping.

[Detailed table of contents](#)

CHAP. 46.

PARSLEY.

Parsley is sown immediately after the vernal equinox, the seed being lightly beaten first in a mortar. It is thought that, by doing this, the parsley will be all the more crisped, or else by taking care to beat it down when sown with a roller or the feet. It is a peculiarity of this plant, that it changes colour: it has the honour, in Achaia, of forming the wreath of the victors in the sacred contests of the Nemean Games.

Detailed table of contents

CHAP. 47.

MINT.

It is at the same season, too, that mint is transplanted; or, if it has not yet germinated, the matted tufts of the old roots are used for the purpose. This plant, too, is no less fond of a humid soil than parsley; it is green in summer and turns yellow in winter. There is a wild kind of mint, known to us as “mentastrum:” it is reproduced by layers, like the vine, or else by planting the branches upside down. It was the sweetness of its smell that caused this plant to change its name among the Greeks, its former name with them being “mintha,” from which the ancient Romans derived their name for it; whereas now, of late, it has been called by them ῥόδουσμον. The mint that is used in the dishes at rustic entertainments pervades the tables far and wide with its agreeable odour. When once planted, it lasts a considerable length of time; it bears, too, a strong resemblance to pennyroyal, a property of which is, as mentioned by us more than once, to flower when kept in our larders.

These other herbs, mint, I mean, and catmint, as well as pennyroyal, are all kept for use in a similar manner; but it is cummin that is the best suited of all the seasoning herbs to squeamish and delicate stomachs. This plant grows on the surface of the soil, seeming hardly to adhere to it, and raising itself aloft from the ground: it ought to be sown in the middle of the summer, in a crumbly, warm soil, more particularly. There is another wild kind of cummin, known by some persons as “rustic,” by others as “Thebaic” cummin: bruised and drunk in water, it is good for pains in the stomach. The cummin most esteemed in our part of the world is that of Carpetania, though elsewhere that of Africa and Æthiopia is more highly esteemed; with some, indeed, this last is pre-ferred to that of Egypt.

Detailed table of contents

CHAP. 48.

OLUSATRUM.

But it is olusatrum, more particularly, that is of so singular a nature, a plant which by the Greeks is called “hippose- linum,” and by others “smyrnium.” This plant is repro- duced from a tear-like gum which exudes from the stem: it is also grown from the roots as well. Those whose business it is to collect the juice of it, say that it has just the flavour of myrrh; and, according to Theophrastus, it is obtained by planting myrrh. The ancients recommended that hipposelinum should be grown in uncultivated spots covered with stones, and in the vicinity of garden walls; but at the present day it is sown in ground that has been twice turned up, between the prevalence of the west winds and the autumnal equinox.

The caper, too, should be sown in dry localities more particularly, the plot being hollowed out and surrounded with an embankment of stones erected around it: if this precaution is not taken, it will spread all over the adjoining land, and entail sterility upon the soil. The caper blossoms in summer, and retains its verdure till the setting of the Vergiliæ; it thrives the best of all in a sandy soil. As to the bad qualities of the caper which grows in the parts beyond the sea, we have already enlarged upon them when speaking of the exotic shrubs.

Detailed table of contents

CHAP. 49.

THE CARAWAY.

The caraway is an exotic plant also, which derives its name, “careum,” from the country in which it was first grown; it is principally employed for culinary purposes. This plant will grow in any kind of soil, and requires to be cultivated just the same way as olusatrum; the most esteemed, however, is that which comes from Caria, and the next best is that of Phrygia.

Detailed table of contents

CHAP. 50.

LOVAGE.

Lovage grows wild in the mountains of Liguria, its native country, but at the present day it is grown everywhere. The cultivated kind is the sweetest of the two, but is far from powerful; by some persons it is known as “panax.” Crateuas, a Greek writer, gives this name, however, to the plant known to us as “cunila bubula;” and others, again, call the conyza or cunilago, cunila, while they call cunila, properly so called, by the name of “thymbra.” With us cunila has another appellation, being generally known as “satureia,” and reckoned among the seasoning plants. It is usually sown in the month of February, and for utility rivals wild marjoram. These two plants are never used together, their properties being so extremely similar; but it is only the wild marjoram of Egypt that is considered superior to cunila.

Detailed table of contents

CHAP. 51.

DITTANDER.

Dittander, too, was originally an exotic plant: it is usually sown after the west winds have begun to prevail. As soon as it begins to shoot, it is cut down close to the ground, after which it is hoed and manured, a process which is repeated the succeeding year. After this, the shoots are fit for use, if the rigour of the winter has not injured them; for it is a plant quite unable to withstand any inclemency of the weather. It grows to the height of a cubit, and has a leaf like that of the laurel, but softer; it is never used except in combination with milk.

[Detailed table of contents](#)

CHAP. 52.

GITH.

Gith is employed by bakers, dill and anise by cooks and medical men. Sacopenium, so extensively used for adulter- ating laser, is also a garden plant, but is only employed for medicinal purposes.

Detailed table of contents

CHAP. 53.

THE POPPY.

There are certain plants which are grown in company with others, the poppy, for instance, sown with cabbages and purs- lain, and rocket with lettuce. Of the cultivated poppy there are three kinds, the first being the white poppy, the seed of which, parched, and mixed with honey, used to be served up in the second course at the tables of the ancients; at the present day, too, the country people sprinkle it on the upper crust of their bread, making it adhere by means of the yolk of eggs, the under crust being seasoned with parsley and gith to heighten the flavour of the flour. The second kind is the black poppy, from which, upon an incision being made in the stalk, a milky juice distils; and the third is that known to the Greeks by the name of “rhœas;” and by us as the wild poppy. This last grows spontaneously, but in fields, more particularly, which have been sown with barley: it bears a strong resemblance to rocket, grows to the height of a cubit, and bears a red flower, which quickly fades; it is to this flower that it is indebted for its Greek name.

As to the other kinds of poppies which spring up spontaneously, we shall have occasion to speak of them when treating of the medicinal plants. That the poppy has always been held in esteem among the Romans, we have a proof in the story related of Tarquinius Superbus, who, by striking down the tallest poppies in his garden, surreptitiously conveyed, unknown to them, his sanguinary message through the envoys who had been sent by his son.

Detailed table of contents

CHAP. 54.

OTHER PLANTS WHICH REQUIRE TO BE SOWN AT THE AUTUMNAL EQUINOX.

There are some other plants, again, which require to be sown together at the time of the autumnal equinox; coriander, for instance, anise, orage, mallows, lapathum, chervil, known to the Greeks as “pæderos,” and mustard, which has so pungent a flavour, that it burns like fire, though at the same time it is remarkably wholesome for the body. This last, though it will grow without cultivation, is considerably improved by being transplanted; though, on the other hand, it is extremely difficult to rid the soil of it when once sown there, the seed when it falls germinating immediately. This seed, when cooked in the saucepan, is employed even for making ragouts, its pungency being rendered imperceptible by boiling; the leaves, too, are boiled just the same way as those of other vegetables.

There are three different kinds of mustard, the first of a thin, slender form, the second, with a leaf like that of the rape, and the third, with that of rocket: the best seed comes from Egypt. The Athenians have given mustard the name of “napy,” others, “thapsi,” and others, again, “saurion.”

Detailed table of contents

CHAP. 55.

WILD THYME; SISYMBRIUM.

Most mountains abound with wild thyme and sisymbrium, those of Thrace, for example, where branches of these wild plants are torn up and brought away for planting, So, too. the people of Sicyon seek for wild thyme on their mountains, and the Athenians on the slopes of Hymettus. Sisymbrium, too, is planted in a similar manner; it grows to the greatest perfection upon the walls of wells, and around fish preserves and ponds.

[Detailed table of contents](#)

CHAP. 56. (9.)

FOUR KINDS OF FERULACEOUS PLANTS. HEMP.

The other garden plants are of the ferulaceous kind, such as fennel, for instance, very grateful to serpents, as already stated, and used for numerous seasonings when dried; thapsia, too, which bears a close resemblance to fennel, and already mentioned by us when speaking of the exotic shrubs. Then, too, there is hemp, a plant remarkably useful for making ropes, and usually sown after the west winds have begun to prevail: the more thickly it is sown, the thinner are the stalks. The seed is gathered when ripe, just after the autumnal equinox, and is dried by the agency of the sun, the wind, or smoke. The hemp itself is plucked just after vintage-time, and is peeled and cleaned by the labourers at night.

The best hemp is that of Alabanda, which is used more particularly for making hunting-nets, and of which there are three varieties. The hemp which lies nearest the bark or the pith is the least valuable, while that which lies in the middle, and hence has the name of “mesa,” is the most esteemed. The hemp of Mylasa occupies the second rank. With reference to the size to which it grows, that of Rosea in the Sabine territory, equals the trees in height.

We have already mentioned two kinds of fennel-giant when speaking of the exotic shrubs: the seed of it is used in Italy for food; the plant, too, admits of being preserved, and, if stored in earthen pots, will keep for a whole year. There are two parts of it that are used for this purpose, the upper stalks and the umbels of the plant. This kind of fennel is sometimes known by the name of “corymbia,” and the parts preserved are called “corymbi.”

Detailed table of contents

CHAP. 57. (10.)

THE MALADIES OF GARDEN PLANTS.

The garden plants, too, like the rest of the vegetable productions, are subject to certain maladies. Thus, for instance, ocimum, when old, degenerates into wild thyme, and sisymbrium into mint, while the seed of an old cabbage produces rape, and vice versâ. Cummin, too, if not kept well hoed, is killed by hæmodorum, a plant with a single stalk, a root similar to a bulb in appearance, and never found except in a thin, meagre soil. Besides this, cummin is liable to a peculiar disease of its own, the scab: ocimum, too, turns pale at the rising of the Dog-star. All plants, indeed, will turn of a yellow complexion on the approach of a woman who has the menstrual discharge upon her.

There are various kinds of insects, too, that breed upon the garden plants — fleas, for instance, upon turnips, and caterpillars and maggots upon radishes, as well as lettuces and cabbages; besides which, the last two are exposed to the attacks of slugs and snails. The leek, too, is infested with peculiar insects of its own; which may very easily be taken, however, by laying dung upon the plants, the insects being in the habit of burrowing in it. Sabinus Tiro says, in his book entitled “Cepurica,” which he dedicated to Mæcenas, that it is not advisable to touch rue, cunila, mint, or ocimum with any implement of iron.

Detailed table of contents

CHAP. 58.

THE PROPER REMEDIES FOR THESE MALADIES. HOW ANTS ARE BEST DESTROYED. THE BEST REMEDIES AGAINST CATER- PILLARS AND FLIES.

The same author recommends as a remedy against ants, which are by no means the slightest plague in a garden that is not kept well watered, to stop up the mouths of their holes with sea-slime or ashes. But the most efficient way of destroying them is with the aid of the plant heliotropium; some persons, too, are of opinion that water in which an unburnt brick has been soaked is injurious to them. The best protection for turnips is to sow a few fitches with them, and for cabbages chickpeas, these having the effect of keeping away caterpillars. If, however, this precaution should have been omitted, and the caterpillars have already made their appearance, the best remedy is to throw upon the vegetables a decoction of wormwood, or else of house-leek, known to some as “aïzoüm,” a kind of herb already mentioned by us. If cabbage-seed, before it is sown, is steeped in the juice of house-leek, the cabbages, it is said, are sure not be attacked by any insect.

It is said, too, that all caterpillars may be effectually exterminated, if the skull of a beast of burden is set up upon a stake in the garden, care being taken to employ that of a female only. There is a story related, too, that a river crab, hung up in the middle of the garden, is a preservative against the attacks of caterpillars. Again, there are some persons who are in the habit of touching with slips of blood-red cornel such plants as they wish to preserve from caterpillars. Flies, too, infest well-watered gardens, and more particularly so, if there happen to be any shrubs there; they may be got rid of; how- ever, by burning galbanum.

(11.) With reference to the deterioration to which seed is subject, there are some seeds which keep better than others, such, for instance, as that of coriander, beet, leeks, cresses, mustard, rocket, cunila, nearly all the pungent plants in fact. The seed, on the other hand, of orage, ocimum, gourds, and cucumbers, is not so good for keeping. All the summer seeds, too, last longer than the winter ones; but scallion seed is the very worst for keeping of them all. But of those, even, which keep the very longest, there is none that will keep beyond four years — for sowing purposes, at least; for culinary purposes, they are fit for use beyond that period.

Detailed table of contents

CHAP. 59.

WHAT PLANTS ARE BENEFITTED BY SALT WATER.

A peculiar remedy for the maladies to which radishes, beet, rue, and cunila are subject, is salt water, which has also the additional merit of conducting very materially to their sweetness and fertility. Other plants, again, are equally benefitted by being watered with fresh water, the most desirable for the purpose being that which is the coldest and the sweetest to drink: pond and drain-water, on the other hand, are not so good, as they are apt to carry the seeds of weeds along with them. It is rain, however, that forms the principal aliment of plants; in addition to which, it kills the insects as they develop themselves upon them.

Detailed table of contents

CHAP. 60. (12.)

THE PROPER METHOD OF WATERING GARDENS.

The proper times for watering are the morning and the evening, to prevent the water from being heated by the sun with the sole exception, however, of ocimum, which requires to be watered at midday; indeed, this plant, it is generally thought, will grow with additional rapidity, if it is watered with boiling water when sown. All plants, when transplanted, grow all the better and larger for it, leeks and turnips more particularly. Transplanting, too, is attended with certain remedial effects, and acts as a preservative to certain plants, such as scallions, for instance, leeks, radishes, parsley, lettuces, rape, and cucumbers. All the wild plants are generally smaller in the leaf and stalk than the cultivated ones, and have more acrid juices, cunila, wild marjoram, and rue, for example. Indeed, it is only the lapathum that is better in a wild state than cultivated: in its cultivated state it is the same plant that is known to us as the “rumix,” being the most vigorous by far of all the plants that are grown; so much so, indeed, that it is said that when it has once taken root, it will last for ever, and can never be extirpated from the soil, more particularly if water happens to be near at hand. Its juices, which are employed only in ptisans, as an article of food, have the effect of imparting to them a softer and more exquisite flavour. The wild variety is employed for many medicinal purposes.

So true it is, that the careful research of man has omitted nothing, that I have even met with a poem, in which I find it stated, that if pellets of goats’ dung, the size of a bean, are hollowed out, and the seed of leeks, rocket, lettuces, parsley, endive, and cresses is inserted in them, and then sown, the plants will thrive in a marvellous degree. Plants in a wild state, it is generally thought, are more dry and acrid than when cultivated.

Detailed table of contents

CHAP. 61.

THE JUICES AND FLAVOURS OF GARDEN HERBS.

This, too, reminds me that I ought to make some mention of the difference between the juices and flavours of the garden herbs, a difference which is more perceptible here than in the fruits even. In *cunila*, for instance, wild marjoram, cresses, and mustard, the flavour is acrid; in wormwood and centaury, bitter; in cucumbers, gourds, and lettuces, watery; and in parsley, anise, and fennel, pungent and odoriferous. The salt flavour is the only one that is not to be found in plants, with the sole exception, indeed, of the chicheling vetch, though even then it is to be found on the exterior surface only of the plant, in the form of a kind of dust which settles there.

Detailed table of contents

CHAP. 62.

PIPERITIS, LIBANOTIS, AND SMYRNIUM.

To come to a full understanding, too, both here as elsewhere, how unfounded are the notions which are generally entertained, I shall take this opportunity of remarking that panax has the flavour of pepper, and siliquastrum even more so, a circumstance to which it owes its name of piperitis: libanotis again, has just the odour of frankincense, and smyrnium of myrrh. As to panax, we have spoken of it at sufficient length already. Libanotis grows in a thin, crumbly soil, and is generally sown in spots exposed to the falling dews; the root, which is just like that of olusatrum, has a smell in no way differing from that of frankincense; when a year old, it is extremely wholesome for the stomach; some persons give it the name of rosmarinum. Smyrniun is a garden herb that grows in similar soils, and has a root which smells like myrrh: siliquastrum, too, is grown in a similar manner.

Other plants, again, differ from the preceding ones, both in smell and taste, anise for example; indeed, so great is the difference in this respect, and in their relative virtues, that not only are the properties of each modified by the other, but quite neutralized even. It is in this way that our cooks correct the flavour of vinegar in their dishes with parsley, and our butlers employ the same plant, enclosed in sachets, for removing a bad odour in wine.

Thus far, then, we have treated of the garden plants, viewed as articles of food only; it remains for us now (for up to the present we have only spoken of their various methods of cultivation, with some succinct details relative thereto), to enlarge upon the more elaborate operations of Nature in this respect; it being quite impossible to come to a full understanding as to the true characteristics of each individual plant, without a knowledge of its medicinal effects, a sublime and truly mysterious manifestation of the wisdom of the Deity, than which nothing can possibly be found of a nature more elevated. It is upon principle that we have thought proper not to enlarge upon the medicinal properties of each plant when treating of it; for it is a quite different class of persons that is interested in knowing their curative properties, and there is no doubt that both classes of readers would have been inconvenienced in a very material degree, if these two points of view had engaged our attention at the same moment. As it is, each class will have its own portion to refer to, while those who desire to do so, will experience no difficulty in uniting them, with reference to any subject of which we may happen to treat.

SUMMARY. — Remarkable facts, narratives, and observations, one thousand one hundred and forty-four.

ROMAN AUTHORS QUOTED. — Maccius Plautus, M. Varro, D. Silanus, Cato the Censor, Hyginus, Virgil, Mucianus, Celsus, Columella, Calpurnius Bassus, Mamilius Sura, Sabinus Tiro, Licinius Macer, Quintus

Hirtius, Vibius Rufus, Cæsennius who wrote the *Cepurica*, Castritius who wrote on the same subject, Firmus who wrote on the same subject, Petrichus who wrote on the same subject.

FOREIGN AUTHORS QUOTED. — Herodotus, Theophrastus, Democritus, Aristomachus, Menander who wrote the *Biochresta*, Anaxiläus.

BOOK XX. REMEDIES DERIVED FROM THE GARDEN PLANTS.

Detailed table of contents

CHAP. 1.

INTRODUCTION.

WE are now about to enter upon an examination of the greatest of all the operations of Nature — we are about to discourse to man upon his aliments, and to compel him to admit that he is ignorant by what means he exists. And let no one, misled by the apparent triviality of the names which we shall have to employ, regard this subject as one that is frivolous or contemptible: for we shall here have to set forth the state of peace or of war which exists between the various departments of Nature, the hatreds or friendships which are maintained by objects dumb and destitute of sense, and all, too, created — a wonderful subject for our contemplation! — for the sake of man alone. To these states, known to the Greeks by the respective appellations “sympathia” and “antipathia,” we are indebted for the first principles of all things; for hence it is that water has the property of extinguishing fire, that the sun absorbs water, that the moon produces it, and that each of those heavenly bodies is from time to time eclipsed by the other.

Hence it is, too, descending from the contemplation of a loftier sphere, that the loadstone possesses the property of attracting iron, and another stone, again, that of repelling it: and that the diamond, that pride of luxury and opulence, though infrangible by every other object, and presenting a resistance that cannot be overcome, is broken asunder by a he-goat’s blood — in addition to numerous other marvels of which we shall have to speak on more appropriate occasions, equal to this or still more wonderful even. My only request is that pardon may be accorded me for beginning with objects of a more humble nature, though still so greatly conducive to our health — I mean the garden plants, of which I shall now proceed to speak.

Detailed table of contents

CHAP. 2. (1.)

THE WILD CUCUMBER; TWENTY-SIX REMEDIES.

We have already stated that there is a wild cucumber, considerably smaller than the cultivated one. From this cucumber the medicament known as “elaterium” is prepared, being the juice extracted from the seed. To obtain this juice the fruit is cut before it is ripe — indeed, if this precaution is not taken at an early period, the seed is apt to spirt out and be productive of danger to the eyes. After it is gathered, the fruit is kept whole for a night, and on the following day an incision is made in it with a reed. The seed, too, is generally sprinkled with ashes, with the view of retaining in it as large a quantity of the juice as possible. When the juice is extracted, it is received in rain water, where it falls to the bottom; after which it is thickened in the sun, and then divided into lozenges, which are of singular utility to mankind for healing dimness of sight, diseases of the eyes, and ulcerations of the eyelids. It is said that if the roots of a vine are touched with this juice, the grapes of it will be sure never to be attacked by birds.

The root, too, of the wild cucumber, boiled in vinegar, is employed in fomentations for the gout, and the juice of it is used as a remedy for tooth-ache. Dried and mixed with resin, the root is a cure for impetigo and the skin diseases known as “psora” and “lichen:” it is good, too, for imposthumes of the parotid glands and inflammatory tumours, and restores the natural colour to the skin when a cicatrix has formed. — The juice of the leaves, mixed with vinegar, is used as an injection for the ears, in cases of deafness.

Detailed table of contents

CHAP. 3.

ELATERIUM; TWENTY-SEVEN REMEDIES.

The proper season for making elaterium is the autumn; and there is no medicament known that will keep longer than this. It begins to be fit for use when three years old; but if it is found desirable to make use of it at an earlier period than this, the acidity of the lozenges may be modified by putting them with vinegar upon a slow fire, in a new earthen pot. The older it is the better, and before now, as we learn from Theophrastus, it has been known to keep so long as two hundred years. Even after it has been kept so long as fifty years, it retains its property of extinguishing a light; indeed, it is the proper way of testing the genuineness of the drug to hold it to the flame and make it scintillate above and below, before finally extinguishing it. The elaterium which is pale, smooth, and slightly bitter, is superior to that which has a grass-green appearance and is rough to the touch.

It is generally thought that the seed of this plant will facilitate conception if a woman carries it attached to her person, before it has touched the ground; and that it has the effect of aiding parturition, if it is first wrapped in ram's wool, and then tied round the woman's loins, without her knowing it, care being taken to carry it out of the house the instant she is delivered.

Those persons who magnify the praises of the wild cucumber say that the very best is that of Arabia, the next being that of Arcadia, and then that of Cyrenæ: it bears a resemblance to the heliotropium, they say, and the fruit, about the size of a walnut, grows between the leaves and branches. The seed, it is said, is very similar in appearance to the tail of a scorpion thrown back, but is of a whitish hue. Indeed, there are some persons who give to this cucumber the name of "scorpionium," and say that its seed, as well as the elaterium, is remarkably efficacious as a cure for the sting of the scorpion. As a purgative, the proper dose of either is from half an obolus to an obolus, according to the strength of the patient, a larger dose than this being fatal. It is in the same proportions, too, that it is taken in drink for phthiriasis and dropsy; applied externally with honey or old olive oil, it is used for the cure of quinsy and affections of the trachea.

Detailed table of contents

CHAP. 4. (2.)

THE ANGUINE OR ERRATIC CUCUMBER: FIVE REMEDIES.

Many authors are of opinion that the wild cucumber is identical with the plant known among us as the “anguine,” and by some persons as the “erratic” cucumber. Objects sprinkled with a decoction of this plant will never be touched by mice. The same authors say, too, that a decoction of it in vinegar, externally applied, gives instantaneous relief in cases of gout and diseases of the joints. As a remedy, too, for lumbago, the seed of it is dried in the sun and pounded, being given in doses of twenty denarii to half a sextarius of water. Mixed with woman’s milk and applied as a liniment, it is a cure for tumours which have suddenly formed.

Elaterium promotes the menstrual discharge; but if taken by females when pregnant, it is productive of abortion. It is good, also, for asthma, and, injected into the nostrils, for the jaundice. Rubbed upon the face in the sun, it removes freckles and spots upon the skin.

[Detailed table of contents](#)

CHAP. 5.

THE CULTIVATED CUCUMBER: NINE REMEDIES.

Many persons attribute all these properties to the cultivated cucumber as well, a plant which even without them would be of very considerable importance, in a medicinal point of view. A pinch of the seed, for instance, in three fingers, beaten up with cummin and taken in wine, is extremely beneficial for a cough: for phrenitis, also, doses of it are administered in woman's milk, and doses of one acetabulum for dysentery. As a remedy for purulent expectorations, it is taken with an equal quantity of cummin; and it is used with hydromel for diseases of the liver. Taken in sweet wine, it is a diuretic; and, in combination with cummin, it is used as an injection for affections of the kidneys.

Detailed table of contents

CHAP. 6.

PEPONES: ELEVEN REMEDIES.

The fruit known as pepones are a cool and refreshing diet, and are slightly relaxing to the stomach. Applications are used of the pulpy flesh in defluxions or pains of the eyes. The root, too, of this plant cures the hard ulcers known to us as “ceria,” from their resemblance to a honeycomb, and it acts as an emetic. Dried and reduced to a powder, it is given in doses of four oboli in hydromel, the patient, immediately after taking it, being made to walk half a mile. This powder is employed also in cosmetics for smoothing the skin. The rind, too, has the effect of promoting vomiting, and, when applied to the face, of clearing the skin; a result which is equally produced by an external application of the leaves of all the cultivated cucumbers. These leaves, mixed with honey, are employed for the cure of the pustules known as “epinyctis;” steeped in wine, they are good, too, for the bites of dogs and of multipedes, insects known to the Greeks by the name of “seps,” of an elongated form, with hairy legs, and noxious to cattle more particularly; the sting being followed by swelling, and the wound rapidly putrifying.

The smell of the cucumber itself is a restorative in fainting fits. It is a well-known fact, that if cucumbers are peeled and then boiled in oil, vinegar, and honey, they are all the more pleasant eating for it.

Detailed table of contents

CHAP. 7. (3.)

THE GOURD: SEVENTEEN REMEDIES. THE SOMPHUS: ONE REMEDY.

There is found also a wild gourd, called “somphos” by the Greeks, empty within (to which circumstance it owes its name), and long and thick in shape, like the finger: it grows nowhere except upon stony spots. The juice of this gourd, when chewed, is very beneficial to the stomach.

Detailed table of contents

CHAP. 8.

THE COLOCYNTHIS: TEN REMEDIES.

There is another variety of the wild gourd, known as the “colocynthis:” this kind is full of seeds, but not so large as the cultivated one. The pale colocynthis is better than those of a grass-green colour. Employed by itself when dried, it acts as a very powerful purgative; used as an injection, it is a remedy for all diseases of the intestines, the kidneys, and the loins, as well as for paralysis. The seed being first removed, it is boiled down in hydromel to one half; after which it is used as an injection, with perfect safety, in doses of four oboli. It is good, too, for the stomach, taken in pills composed of the dried powder and boiled honey. In jaundice seven seeds of it may be taken with beneficial effects, with a draught of hydromel immediately after.

The pulp of this fruit, taken with wormwood and salt, is a remedy for toothache, and the juice of it, warmed with vinegar, has the effect of strengthening loose teeth. Rubbed in with oil, it removes pains of the spine, loins, and hips: in addition to which, really a marvellous thing to speak of! the seeds of it, in even numbers, attached to the body in a linen cloth, will cure, it is said, the fevers to which the Greeks have given the name of “periodic.” The juice, too, of the cultivated gourd shred in pieces, applied warm, is good for ear-ache, and the flesh of the inside, used without the seed, for corns on the feet and the suppurations known to the Greeks as “apostemata.” When the pulp and seeds are boiled together, the decoction is good for strengthening loose teeth, and for preventing toothache; wine, too, boiled with this plant, is curative of defluxions of the eyes. The leaves of it, bruised with fresh cypress-leaves, or the leaves alone, boiled in a vessel of potters’ clay and beaten up with goose-grease, and then applied to the part affected, are an excellent cure for wounds. Fresh shavings of the rind are used as a cooling application for gout, and burning pains in the head, in infants more particularly; they are good, too, for erysipelas, whether it is the shavings of the rind or the seeds of the plant that are applied to the part affected. The juice of the scrapings, employed as a liniment with rose-oil and vinegar, moderates the burning heats of fevers; and the ashes of the dried fruit applied to burns are efficacious in a most remarkable degree.

Chrysippus, the physician, condemned the use of the gourd as a food: it is generally agreed, however, that it is extremely good for the stomach, and for ulcerations of the intestines and of the bladder.

CHAP. 9.

RAPE; NINE REMEDIES.

Rape, too, has its medicinal properties. Warmed, it is used as an application for the cure of chilblains, in addition to which, it has the effect of protecting the feet from cold. A hot decoction of rape is employed for the cure of cold gout; and raw rape, beaten up with salt, is good for all maladies of the feet. Rape-seed, used as a liniment, and taken in drink, with wine, is said to have a salutary effect against the stings of serpents, and various narcotic poisons; and there are many persons who attribute to it the properties of an antidote, when taken with wine and oil.

Democritus has entirely repudiated the use of rape as an article of food, in consequence of the flatulence which it produces; while Diocles, on the other hand, has greatly extolled it, and has even gone so far as to say that it acts as an aphrodisiac. Dionysius, too, says the same of rape, and more particularly if it is seasoned with rocket; he adds, also, that roasted, and then applied with grease, it is excellent for pains in the joints.

[Detailed table of contents](#)

CHAP. 10.

WILD RAPE: ONE REMEDY.

Wild rape is mostly found growing in the fields; it has a tufted top, with a white seed, twice as large as that of the poppy. This plant is often employed for smoothing the skin of the face and the body generally, meal of fitches, barley, wheat, and lupines, being mixed with it in equal proportions.

The root of the wild rape is applied to no useful purpose whatever.

Detailed table of contents

CHAP. 11. (4.)

TURNIPS; THOSE KNOWN AS BUNION AND BUNIAS: FIVE REMEDIES.

The Greeks distinguish two kinds of turnips, also, as employed in medicine. The turnip with angular stalks and a flower like that of anise, and known by them as “bunion,” is good for promoting the menstrual discharge in females and for affections of the bladder; it acts, also, as a diuretic. For these purposes, a decoction of it is taken with hydromel, or else one drachma of the juice of the plant. The seed, parched, and then beaten up, and taken in warm water, in doses of four cyathi, is a good remedy for dysentery; it will stop the passage of the urine, however, if linseed is not taken with it.

The other kind of turnip is known by the name of “bunias,” and bears a considerable resemblance to the radish and the rape united, the seed of it enjoying the reputation of being a remedy for poisons; hence it is that we find it employed in antidotes.

Detailed table of contents

CHAP. 12.

THE WILD RADISH, OR ARMORACIA: ONE REMEDY.

We have already said, that there is also a wild radish. The most esteemed is that of Arcadia, though it is also found growing in other countries as well. It is only efficacious as a diuretic, being in other respects of a heating nature. In Italy, it is known also by the name of “armoracia.”

Detailed table of contents

CHAP. 13.

THE CULTIVATED RADISH: FORTY-THREE REMEDIES.

The cultivated radish, too, in addition to what we have already said of it, purges the stomach, attenuates the phlegm, acts as a diuretic, and detaches the bilious secretions. A decoction of the rind of radishes in wine, taken in the morning in doses of three cyathi, has the effect of breaking and expelling calculi of the bladder. A decoction, too, of this rind in vinegar and water, is employed as a liniment for the stings of serpents. Taken fasting in the morning with honey, radishes are good for a cough. Parched radish-seed, as well as radishes themselves, chewed, is useful for pains in the sides. A decoction of the leaves, taken in drink, or else the juice of the plant taken in doses of two cyathi, is an excellent remedy for phthiriasis. Pounded radishes, too, are employed as a liniment for inflammations under the skin, and the rind, mixed with honey, for bruises of recent date. Lethargic persons are recommended to eat them as hot as possible, and the seed, parched and then pounded with honey, will give relief to asthmatic patients.

Radishes, too, are useful as a remedy for poisons, and are employed to counteract the effects of the sting of the cerastes and the scorpion: indeed, after having rubbed the hands with radishes or radish-seed, we may handle those reptiles with impunity. If a radish is placed upon a scorpion, it will cause its death. Radishes are useful, too, in cases of poisoning by fungi or henbane; and according to Nicander, they are salutary against the effects of bullock's blood, when drunk. The two physicians of the name of Apollodorus, prescribe radishes to be given in cases of poisoning by mistletoe; but whereas Apollodorus of Citium recommends radish-seed pounded in water, Apollodorus of Tarentum speaks of the juice. Radishes diminish the volume of the spleen, and are beneficial for maladies of the liver and pains in the loins: taken, too, with vinegar or mustard, they are good for dropsy and lethargy, as well as epilepsy and melancholy. Praxagoras recommends that radishes should be given for the iliac passion, and Plistonicius for the cœliac disease.

Radishes are good, too, for curing ulcerations of the intestines and suppurations of the thoracic organs, if eaten with honey. Some persons say, however, that for this purpose they should be boiled in earth and water; a decoction which, according to them, promotes the menstrual discharge. Taken with vinegar or honey, radishes expel worms from the intestines; and a decoction of them boiled down to one-third, taken in wine, is good for intestinal hernia. Employed in this way, too, they have the effect of drawing off the superfluous blood. Medius recommends them to be given boiled to persons troubled with spitting of blood, and to women who are suckling, for the purpose of increasing the milk. Hippocrates recommends females whose

hair falls off, to rub the head with radishes, and he says that for pains of the uterus, they should be applied to the navel.

Radishes have the effect, too, of restoring the skin, when scarred, to its proper colour; and the seed, steeped in water, and applied topically, arrests the progress of ulcers known as phagedænic. Democritus regards them, taken with the food, as an aphrodisiac; and it is for this reason, perhaps, that some persons have spoken of them as being injurious to the voice. The leaves, but only those of the long radish, are said to have the effect of improving the eyesight.

When radishes, employed as a remedy, act too powerfully, it is recommended that hyssop should be given immediately; there being an antipathy between these two plants. For dulness of hearing, too, radish-juice is injected into the ear. To promote vomiting, it is extremely beneficial to eat radishes fasting.

CHAP. 14.

THE PARSNIP: FIVE REMEDIES. THE HIBISCUM, WILD MALLOW, OR
PLISTOLOCHIA: ELEVEN REMEDIES.

The hibiscum, by some persons known as the wild mallow, and by others as the “plistolochia,” bears a strong resemblance to the parsnip; it is good for ulcerations of the cartilages, and is employed for the cure of fractured bones. The leaves of it, taken in water, relax the stomach; they have the effect, also, of keeping away serpents, and, employed as a liniment, are a cure for the stings of bees, wasps, and hornets. The root, pulled up before sunrise, and wrapped in wool of the colour known as “native,” taken from a sheep which has just dropped a ewe lamb, is employed as a bandage for scrofulous swellings, even after they have suppurated. Some persons are of opinion, that for this purpose the root should be dug up with an implement of gold, and that care should be taken not to let it touch the ground.

Celsus, too, recommends this root to be boiled in wine, and applied in cases of gout unattended with swelling.

Detailed table of contents

CHAP. 15. (5.)

THE STAPHYLINOS, OR WILD PARSNIP: TWENTY-TWO REMEDIES.

The staphylinos, or, as some persons call it, “erratic parsnip,” is another kind. The seed of this plant, pounded and taken in wine, reduces swelling of the abdomen, and alleviates hysterical suffocations and pains, to such a degree as to restore the uterus to its natural condition. Used as a liniment, also, with raisin wine, it is good for pains of the bowels in females; for men, too, beaten up with an equal proportion of bread, and taken in wine, it may be found beneficial for similar pains. It is a diuretic also, and it will arrest the progress of phagedænic ulcers, if applied fresh with honey, or else dried and sprinkled on them with meal.

Dieuches recommends the root of it to be given, with hydromel, for affections of the liver and spleen, as also the sides, loins, and kidneys; and Cleophrantus prescribes it for dysentery of long standing. Philistio says that it should be boiled in milk, and for strangury he prescribes four ounces of the root. Taken in water, he recommends it for dropsy, as well as in cases of opisthotony, pleurisy, and epilepsy. Persons, it is said, who carry this plant about them, will never be stung by serpents, and those who have just eaten of it will receive no hurt from them. Mixed with axle-grease, it is applied to parts of the body stung by reptiles; and the leaves of it are eaten as a remedy for indigestion.

Orpheus has stated that the staphylinos acts as a philtre, most probably because, a very-well-established fact, when employed as a food, it is an aphrodisiac; a circumstance which has led some persons to state that it promotes conception. In other respects the cultivated parsnip has similar properties; though the wild kind is more powerful in its operation, and that which grows in stony soils more particularly. The seed, too, of the cultivated parsnip, taken in wine, or vinegar and water, is salutary for stings inflicted by scorpions. By rubbing the teeth with the root of this plant, tooth-ache is removed.

[Detailed table of contents](#)

CHAP. 16.

GINGIDION: ONE REMEDY.

The Syrians devote themselves particularly to the cultivation of the garden, a circumstance to which we owe the Greek proverb, “There is plenty of vegetables in Syria.”

Among other vegetables, that country produces one very similar to the staphylinos, and known to some persons as “gingidion,” only that it is smaller than the staphylinos and more bitter, though it has just the same properties. Eaten either raw or boiled, it is very beneficial to the stomach, as it entirely absorbs all humours with which it may happen to be surcharged.

[Detailed table of contents](#)

CHAP. 17.

THE SKIRRET: ELEVEN REMEDIES.

The wild skirret, too, is very similar to the cultivated kind, and is productive of similar effects. It sharpens the stomach, and, taken with vinegar flavoured with silphium, or with pepper and hydromel, or else with garum, it promotes the appetite. According to Opion, it is a diuretic, and acts as an aphrodisiac. Diocles is also of the same opinion; in addition to which, he says that it possesses cordial virtues for convalescents, and is extremely beneficial after frequent vomitings.

Heraclides has prescribed it against the effects of mercury, and for occasional impotence, as also generally for patients when convalescent. Hicesius says that skirrets would appear to be prejudicial to the stomach, because no one is able to eat three of them following; still, however, he looks upon them as beneficial to patients who are just resuming the use of wine. The juice of the cultivated skirret, taken in goats-milk, arrests looseness of the stomach.

[Detailed table of contents](#)

CHAP. 18.

SILE, OR HARTWORT: TWELVE REMEDIES.

As the similitude which exists between their Greek names has caused most persons to mistake the one for the other, we have thought it as well to give some account here of sile or hartwort, though it is a plant which is very generally known. The best hartwort is that of Massilia, the seed of it being broad and yellow; and the next best is that of Æthiopia, the seed of which is of a darker hue. The Cretan hartwort is the most odoriferous of the several kinds. The root of this plant has a pleasant smell; the seed of it is eaten by vultures, it is said. Hartwort is useful to man for inveterate coughs, ruptures, and convulsions, being usually taken in white wine; it is employed also in cases of opisthotony, and for diseases of the liver, as well as for griping pains in the bowels and for strangury, in doses of two or three spoonfuls at a time.

The leaves of this plant are useful also, and have the effect of aiding parturition — in animals even: indeed, it is generally said that roes, when about to bring forth, are in the habit of eating these leaves in particular. They are topically applied, also, in erysipelas; and either the leaves or the seed, taken fasting in the morning, are very beneficial to the digestion. Hartwort has the effect, too, of arresting looseness in cattle, either bruised and put into their drink, or else eaten by them after it has been chewed with salt. When oxen are in a diseased state, it is beaten up and poured into their food.

[Detailed table of contents](#)

CHAP. 19.

ELECAMPANE: ELEVEN REMEDIES.

Elecampane, too, chewed fasting, has the effect of strengthening the teeth, if, from the moment that it is plucked, it is not allowed to touch the ground: a confection of it is a cure for cough. The juice of the root boiled is an expellent of intestinal tapeworm; and dried in the shade and reduced to powder, the root is curative in cases of cough, convulsions, flatulency, and affections of the trachea. It is useful too, for the bites of venomous animals; and the leaves steeped in wine are applied topically for pains in the loins.

[Detailed table of contents](#)

CHAP. 20.

ONIONS: TWENTY-SEVEN REMEDIES.

There are no such things in existence as wild onions. The cultivated onion is employed for the cure of dimness of sight, the patient being made to smell at it till tears come into the eyes: it is still better even if the eyes are rubbed with the juice. It is said, too, that onions are soporific, and that they are a cure for ulcerations of the mouth, if chewed with bread. Fresh onions in vinegar, applied topically, or dried onions with wine and honey, are good for the bites of dogs, care being taken not to remove the bandage till the end of a couple of days. Applied, too, in the same way, they are good for healing excoriations. Roasted in hot ashes, many persons have applied them topically, with barley meal, for defluxions of the eyes and ulcerations of the genitals. The juice, too, is employed as an ointment for sores of the eyes, albugo, and argema. Mixed with honey, it is used as a liniment for the stings of serpents and all kinds of ulcerous sores. In combination with woman's milk, it is employed for affections of the ears; and in cases of singing in the ears and hardness of hearing, it is injected into those organs with goose-grease or honey. In cases where persons have been suddenly struck dumb, it has been administered to them to drink, mixed with water. In cases, too, of toothache, it is sometimes introduced into the mouth as a gargle for the teeth; it is an excellent remedy also for all kinds of wounds made by animals, scorpions more particularly.

In cases of alopecy and itch-scab, bruised onions are rubbed on the parts affected: they are also given boiled to persons afflicted with dysentery or lumbago. Onion peelings, burnt to ashes and mixed with vinegar, are employed topically for stings of serpents and multipedes.

In other respects, there are remarkable differences of opinion among medical men. The more modern writers have stated that onions are good for the thoracic organs and the digestion, but that they are productive of flatulency and thirst. The school of Asclepiades maintains that, used as an aliment, onions impart a florid colour to the complexion, and that, taken fasting every day, they are promoters of robustness and health; that as a diet, too, they are good for the stomach by acting upon the spirits, and have the effect of relaxing the bowels. He says, too, that, employed as a suppository, onions disperse piles, and that the juice of them, taken in combination with juice of fennel, is wonderfully beneficial in cases of incipient dropsy. It is said, too, that the juice, taken with rue and honey, is good for quinsy, and has the effect of dispelling lethargy. Varro assures us that onions, pounded with salt and vinegar and then dried, will never be attacked by worms.

CHAP. 21. (6.)

CUTLEEK: THIRTY-TWO REMEDIES.

Cutleek has the effect of stanching bleeding at the nose, the nostrils being plugged with the plant, pounded, or else mixed with nut-galls or mint. The juice of it, taken with woman's milk, arrests floodings after a miscarriage; and it is remedial in cases even of inveterate cough, and of affections of the chest and lungs. The leaves, applied topically, are employed for the cure of pimples, burns, and epinictis — this last being the name given to an ulcer, known also as "syce," situate in the corner of the eye, from which there is a continual running: some persons, however, give this name to livid pustules, which cause great restlessness in the night. Other kinds of ulcers, too, are treated with leeks beaten up with honey: used with vinegar, they are extensively employed also for the bites of wild beasts, as well as of serpents and other venomous creatures. Mixed with goats' gall, or else honied wine in equal proportions, they are used for affections of the ears, and, combined with woman's milk, for singing in the ears. In cases of head-ache, the juice is injected into the nostrils, or else into the ear at bed-time, two spoonfuls of juice to one of honey.

This juice is taken too with pure wine, for the stings of serpents and scorpions, and, mixed with a semi-sextarius of wine, for lumbago. The juice, or the leek itself, eaten as a food, is very beneficial to persons troubled with spitting of blood, phthisis, or inveterate catarrhs; in cases also of jaundice or dropsy, and for nephretic pains, it is taken in barley-water, in doses of one acetabulum of juice. The same dose, too, mixed with honey, effectually purges the uterus. Leeks are eaten, too, in cases of poisoning by fungi, and are applied topically to wounds: they act also as an aphrodisiac, allay thirst, and dispel the effects of drunkenness; but they have the effect of weakening the sight and causing flatulency, it is said, though, at the same time, they are not injurious to the stomach, and act as an aperient. Leeks impart a remarkable clearness to the voice.

Detailed table of contents

CHAP. 22.

BULBED LEEK: THIRTY-NINE REMEDIES.

Bulbed leek produces the same effects as cut-leek, but in a more powerful degree. To persons troubled with spitting of blood, the juice of it is given, with powdered nut-galls or frankincense, or else gum acacia. Hippocrates, however, prescribes it without being mixed with anything else, and expressed himself of opinion that it has the property of opening the uterus when contracted, and that taken as an aliment by females, it is a great promoter of fecundity. Beaten up and mixed with honey, it cleanses ulcerous sores. It is good for the cure of coughs, catarrhs, and all affections of the lungs and of the trachea, whether given in the form of a ptisan, or eaten raw, the head excepted: it must be taken, however, without bread, and upon alternate days, and this even if there should be purulent expectorations.

Taken in this form, it greatly improves the voice, and acts as an aphrodisiac, and as a promoter of sleep. The heads, boiled in a couple of waters, arrest looseness of the bowels, and fluxes of long standing; and a decoction of the outer coat acts as a dye upon grey hair.

[Detailed table of contents](#)

CHAP. 23.

GARLIC: SIXTY-ONE REMEDIES.

Garlic has very powerful properties, and is of great utility to persons on changes of water or locality. The very smell of it drives away serpents and scorpions, and, according to what some persons say, it is a cure for wounds made by every kind of wild beast, whether taken with the drink or food, or applied topically. Taken in wine, it is a remedy for the sting of the hæmorrhoids more particularly, acting as an emetic. We shall not be surprised too, that it acts as a powerful remedy for the bite of the shrew-mouse, when we find that it has the property of neutralizing aconite, otherwise known as “pardalianches.” It neutralizes henbane, also, and cures the bites of dogs, when applied with honey to the wound. It is taken in drink also for the stings of serpents; and of its leaves, mixed with oil, a most valuable liniment is made for bruises on the body, even when they have swelled and formed blisters.

Hippocrates is of opinion also, that fumigations made with garlic have the effect of bringing away the after-birth; and he used to employ the ashes of garlic, mixed with oil, for the cure of running ulcers of the head. Some persons have prescribed boiled garlic for asthmatic patients; while others, again, have given it raw. Diocles prescribes it, in combination with centaury, for dropsy, and to be taken in a split fig, to promote the alvine evacuations: taken fresh, however, in unmixed wine, with coriander, it is still more efficacious for that purpose. Some persons have given it, beaten up in milk, for asthma. Praxagoras used to prescribe garlic, mixed with wine, for jaundice, and with oil and pottage for the iliac passion: he employed it also in a similar form, as a liniment for scrofulous swellings of the neck.

The ancients used to give raw garlic in cases of madness, and Diocles administered it boiled for phrenitis. Beaten up, and taken in vinegar and water, it is very useful as a gargle for quinsy. Three heads of garlic, beaten up in vinegar, give relief in toothache: and a similar result is obtained by rinsing the mouth with a decoction of garlic, and inserting pieces of it in the hollow teeth. Juice of garlic is sometimes injected into the ears with goose-grease, and, taken in drink, or similarly injected, in combination with vinegar and nitre, it arrests phthiriasis and porrigo. Boiled with milk, or else beaten up and mixed with soft cheese, it is a cure for catarrhs. Employed in a similar manner, and taken with pease or beans, it is good for hoarseness, but in general it is found to be more serviceable cooked than raw, and boiled than roasted: in this last state, however, it is more beneficial to the voice. Boiled in oxymel, it has the effect of expelling tape-worm and other intestinal worms; and a pottage made of it is a cure for tetanus. A decoction of garlic is applied topically for pains in the temples; and first boiled and then beaten up with honey, it is good for blisters. A decoction of it, with stale grease, or milk,

is excellent for a cough; and where persons are troubled with spitting of blood or purulent matter, it may be roasted in hot ashes, and taken with honey in equal proportions. For convulsions and ruptures it is administered in combination with salt and oil; and, mixed with grease, it is employed for the cure of suspected tumours.

Mixed with sulphur and resin, garlic draws out the humours from fistulous sores, and employed with pitch, it will extract an arrow even from the wound. In cases of leprosy, lichen, and eruptions of the skin, it acts as a detergent, and effects a cure, in combination with wild marjoram, or else reduced to ashes, and applied as a liniment with oil and garum. It is employed in a similar manner, too, for erysipelas; and, reduced to ashes, and mixed with honey, it restores contused or livid spots on the skin to their proper colour. It is generally believed, too, that taken in the food and drink, garlic is a cure for epilepsy, and that a clove of it, taken in astringent wine, with an obolus' weight of silphium, will have the effect of dispelling quartan fever. Garlic cures coughs also, and sup- purations of the chest, however violent they may be; to obtain which result, another method is followed, it being boiled with broken beans, and employed as a diet till the cure is fully effected. It is a soporific also, and in general imparts to the body an additional ruddiness of colour.

Garlic acts as an aphrodisiac, beaten up with fresh coriander, and taken in pure wine. The inconveniences which result from the use of it, are dimness of the sight and flatulency; and if taken in too large quantities, it does injury to the stomach, and creates thirst. In addition to these particulars, mixed with spelt flour, and given to poultry in their food, it preserves them from attacks of the pip. Beasts of burden, it is said, will void their urine all the more easily, and without any pain, if the genitals are rubbed with garlic.

[Detailed table of contents](#)

CHAP. 24.

THE LETTUCE: FORTY-TWO REMEDIES. THE GOAT- LETTUCE: FOUR REMEDIES.

The first kind of lettuce which grows spontaneously, is the one that is generally known as “goat-lettuce;” thrown into the sea, this vegetable has the property of instantaneously killing all the fish that come into its vicinity. The milky juice of this lettuce, left to thicken and then put into vinegar, is given in doses of two oboli, with the addition of one cyathus of water, to patients for dropsy. The stalk and leaves, bruised and sprinkled with salt, are used for the cure of wounds of the sinews. Pounded with vinegar, and employed as a gargle in the morning twice a month, they act as a preventive of tooth-ache.

[Detailed table of contents](#)

CHAP. 25.

CÆSAPON: ONE REMEDY. ISATIS: ONE REMEDY. THE WILD LETTUCE: SEVEN
REMEDIES.

There is a second kind of wild lettuce, known by the Greeks as “cæsapon.” The leaves of this lettuce, applied as a liniment with polenta, are used for the cure of ulcerous sores. This plant is found growing in the fields. A third kind, again, grows in the woods; the name given to it is “isatis.” The leaves of this last, beaten up and applied with polenta, are very useful for the cure of wounds. A fourth kind is used by dyers of wool; in the leaves it would resemble wild lapa- thum, were it not that they are more numerous and darker. This lettuce has the property of stanching blood, and of healing phagedænic sores and putrid spreading ulcers, as well as tumours before suppuration. Both the root as well as the leaves are good, too, for erysipelas; and a decoction of it is drunk for affections of the spleen. Such are the properties peculiar to each of these varieties.

[Detailed table of contents](#)

CHAP. 26.

HAWK-WEED: SEVENTEEN REMEDIES.

The properties which are common to all the wild varieties are whiteness, a stem sometimes as much as a cubit in length, and a roughness upon the stalk and leaves. Among these plants there is one with round, short leaves, known to some persons as “hieracion;” from the circumstance that the hawk tears it open and sprinkles its eyes with the juice, and so dispels any dimness of sight of which it is apprehensive. The juice of all these plants is white, and in its properties resembles that of the poppy. It is collected at harvest-time, by making incisions in the stalk, and is kept in new earthen vessels, being renowned as a remedy for numerous maladies. Mixed with woman’s milk, it is a cure for all diseases of the eyes, such as argema for instance, films on the eyes, scars and inflammations of all kinds, and dimness of the sight more particularly. It is applied to the eyes, too, in wool, as a remedy for defluxions of those organs.

This juice also purges the bowels, taken in doses of two oboli in vinegar and water. Drunk in wine it is a cure for the stings of serpents, and the leaves and stalk of the plant are pounded and taken in vinegar. They are employed also as a liniment for wounds, the sting of the scorpion more particularly; combined, too, with oil and vinegar, they are similarly applied for the bite of the phalangium. They have the effect, also, of neutralizing other poisons, with the exception of those which kill by suffocation or by attacking the bladder, as also with the exception of white lead. Steeped in oxymel, they are applied to the abdomen for the purpose of drawing out vicious humours of the intestines. The juice is found good, also, in cases of retention of the urine. Crateuas prescribes it to be given to dropsical patients, in doses of two oboli, with vinegar and one cyathus of wine.

Some persons collect the juice of the cultivated lettuce as well, but it is not so efficacious as the other. We have already made mention, to some extent, of the peculiar properties of the cultivated lettuce, such as promoting sleep, allaying the sexual passions, cooling the body when heated, purging the stomach, and making blood. In addition to these, it possesses no few properties besides; for it has the effect of removing flatulency, and of dispelling eructations, while at the same time it promotes the digestion, without ever being indigestible itself.

Indeed, there is no article of diet known that is a greater stimulant to the appetite, or which tends in a greater degree to modify it; it being the extent, either way, to which it is eaten that promotes these opposite results. In the same way, too, lettuces eaten in too large quantities are laxative, but taken in moderation they are binding. They have the effect, also, of attenuating the tough, viscous, phlegm, and, according to what some persons say, of sharpening the senses. They are extremely serviceable, too, to debilitated

stomachs; for which purpose * * oboli of sour sauce is added to them, the sharp ness of which is modified by the application of sweet wine, to make it of the same strength as vinegar-sauce. If, again, the phlegm with which the patient is troubled is extremely tough and viscous, wine of squills or of wormwood is employed; and if there is any cough perceptible, hyssop wine is mixed as well.

Lettuces are given with wild endive for coeliac affections, and for obstructions of the thoracic organs. White lettuces, too, are prescribed in large quantities for melancholy and affections of the bladder. Praxagoras recommends them for dysentery. Lettuces are good, also, for recent burns, before blisters have made their appearance: in such cases they are applied with salt. They arrest spreading ulcers, being applied at first with saltpetre, and afterwards with wine. Beaten up, they are applied topically for erysipelas; and the stalks, beaten up with polenta, and applied with cold water, are soothing for luxations of the limbs and spasmodic contractions; used, too, with wine and polenta, they are good for pimples and eruptions. For cholera lettuces have been given, cooked in the saucepan, in which case it is those with the largest stalk and bitter that are the best: some persons administer them, also, as an injection, in milk. These stalks boiled, are remarkably good, it is said, for the stomach: the summer lettuce, too, more particularly, and the bitter, milky lettuce, of which we have already made mention as the “meconis,” have a soporific effect. This juice, in combination with woman’s milk, is said to be extremely beneficial to the eyesight, if applied to the head in good time; it is a remedy, too, for such maladies of the eyes as result from the action of cold.

I find other marvellous praises lavished upon the lettuce, such, for instance, as that, mixed with Attic honey, it is no less beneficial for affections of the chest than abrotonum; that the menstrual discharge is promoted in females by using it as a diet; that the seed, too, of the cultivated lettuce is administered as a remedy for the stings of scorpions, and that pounded, and taken in wine, it arrests all libidinous dreams and imaginations during sleep; that water, too, which affects the brain will have no injurious effects upon those who eat lettuce. Some persons have stated, however, that if lettuces are eaten too frequently they will prove injurious to the eye sight.

Detailed table of contents

CHAP. 27. (8.)

BEET: TWENTY-FOUR REMEDIES.

Nor are the two varieties of the beet without their remedial properties. The root of either white or black beet, if hung by a string, fresh-gathered, and softened with water, is said to be efficacious for the stings of serpents. White beet, boiled and eaten with raw garlic, is taken for tapeworm; the root, too, of the black kind, similarly boiled in water, removes porrigo; indeed, it is generally stated, that the black beet is the more efficacious of the two. The juice of black beet is good for inveterate head-aches and vertigo, and injected into the ears, it stops singing in those organs. It is a diuretic, also, and employed in injections is a cure for dysentery and jaundice.

This juice, used as a liniment, allays tooth-ache, and is good for the stings of serpents; but due care must be taken that it is extracted from this root only. A decoction, too, of beet-root is a remedy for chilblains.

A liniment of white beet-root applied to the forehead, arrests defluxions of the eyes, and mixed with a little alum it is an excellent remedy for erysipelas. Beaten up, and applied without oil, it is a cure for excoriations. In the same way, too, it is good for pimples and eruptions. Boiled, it is applied topically to spreading ulcers, and in a raw state it is employed in cases of alopecia, and running ulcers of the head. The juice, injected with honey into the nostrils, has the effect of clearing the head. Beet-root is boiled with lentils and vinegar, for the purpose of relaxing the bowels; if it is boiled, however, some time longer, it will have the effect of arresting fluxes of the stomach and bowels.

Detailed table of contents

CHAP. 28.

LIMONION, OR NEUROIDES: THREE REMEDIES.

There is a wild beet, too, known by some persons as “limonion,” and by others as “neuroides;” it has leaves much smaller and thinner than the cultivated kind, and lying closer together. These leaves amount often to eleven in number, the stalk resembling that of the lily. The leaves of this plant are very useful for burns, and have an astringent taste in the mouth: the seed, taken in doses of one acetabulum, is good for dysentery. It is said that a decoction of beet with the root has the property of taking stains out of cloths and parchment.

[Detailed table of contents](#)

CHAP. 29.

ENDIVE: THREE REMEDIES.

Endive, too, is not without its medicinal uses. The juice of it, employed with rose oil and vinegar, has the effect of allaying headache; and taken with wine, it is good for pains in the liver and bladder: it is used, also, topically, for defluxions of the eyes. The spreading endive has received from some persons among us the name of “ambula.” In Egypt, the wild endive is known as “cichorium,” the cultivated kind being called “seris.” This last is smaller than the other, and the leaves of it more full of veins.

Detailed table of contents

CHAP. 30.

CICHORIUM OR CHRESTON, OTHERWISE CALLED PANCRATION, OK AMBULA:
TWELVE REMEDIES.

Wild endive or cichorium has certain refreshing qualities, used as an aliment. Applied by way of liniment, it disperses abscesses, and a decoction of it loosens the bowels. It is also very beneficial to the liver, kidneys, and stomach. A decoction of it in vinegar has the effect of dispelling the pains of strangury; and, taken in honied wine, it is a cure for the jaundice, if unattended with fever. It is beneficial, also, to the bladder, and a decoction of it in water promotes the menstrual discharge to such an extent as to bring away the dead fœtus even.

In addition to these qualities, the magicians state that persons who rub themselves with the juice of the entire plant, mixed with oil, are sure to find more favour with others, and to obtain with greater facility anything they may desire. This plant, in consequence of its numerous salutary virtues, has been called by some persons “chreston,” and “pancration” by others.

CHAP. 31.

HEDYPNOÏS: FOUR REMEDIES.

There is a sort of wild endive, too, with a broader leaf, known to some persons as “hedypnoïs.” Boiled, it acts as an astringent upon a relaxed stomach, and eaten raw, it is productive of constipation. It is good, too, for dysentery, when eaten with lentils more particularly. This variety, as well as the preceding one, is useful for ruptures and spasmodic contractions, and relieves persons who are suffering from spermatorrhœa.

[Detailed table of contents](#)

CHAP. 32.

SERIS, THREE VARIETIES OF IT: SEVEN REMEDIES BORROWED FROM IT.

The vegetable, too, called “seris,” which bears a considerable resemblance to the lettuce, consists of two kinds. The wild, which is of a swarthy colour, and grows in summer, is the best of the two; the winter kind, which is whiter than the other, being inferior. They are both of them bitter, but are extremely beneficial to the stomach, when distressed by humours more particularly. Used as food with vinegar, they are cooling, and, employed as a liniment, they dispel other humours besides those of the stomach. The roots of the wild variety are eaten with polenta for the stomach; and in cardiac diseases they are applied topically above the left breast. Boiled in vinegar, all these vegetables are good for the gout, and for patients troubled with spitting of blood or spermatorrhœa; the decoction being taken on alternate days.

Petronius Diodotus, who has written a medical Anthology, utterly condemns seris, and employs a multitude of arguments to support his views: this opinion of his is opposed, however, to that of all other writers on the subject.

CHAP. 33. (9).

THE CABBAGE: EIGHTY-SEVEN REMEDIES. RECIPES MENTIONED BY CATO.

It would be too lengthy a task to enumerate all the praises of the cabbage, more particularly as the physician Chrysippus has devoted a whole volume to the subject, in which its virtues are described in reference to each individual part of the human body. Dieuches has done the same, and Pythagoras too, in particular. Cato, too, has not been more sparing in its praises than the others; and it will be only right to examine the opinions which he expresses in relation to it, if for no other purpose than to learn what medicines the Roman people made use of for six hundred years.

The most ancient Greek writers have distinguished three varieties of the cabbage; the curly cabbage, to which they have given the name of “selinoïdes,” from the resemblance of its leaf to that of parsley, beneficial to the stomach, and moderately relaxing to the bowels; the “helia,” with broad leaves running out from the stalk — a circumstance, owing to which some persons have given it the name of “caulodes” — of no use whatever in a medicinal point of view; and a third, the name of which is properly “crambe,” with thinner leaves, of simple form, and closely packed, more bitter than the others, but extremely efficacious in medicine.

Cato esteems the curly cabbage the most highly of all, and next to it, the smooth cabbage with large leaves and a thick stalk. He says that it is a good thing for headache, dimness of the sight, and dazzling of the eyes, the spleen, stomach, and thoracic organs, taken raw in the morning, in doses of two acetabula, with oxymel, coriander, rue, mint, and root of silphium. He says, too, that the virtue of it is so great that the very person even who beats up this mixture feels himself all the stronger for it; for which reason he recommends it to be taken mixed with these condiments, or, at all events, dressed with a sauce compounded of them. For the gout, too, and diseases of the joints, a liniment of it should be used, he says, with a little rue and coriander, a sprinkling of salt, and some barley meal: the very water even in which it has been boiled is wonderfully efficacious, according to him, for the sinews and joints. For wounds, either recent or of long standing, as also for carcinoma, which is incurable by any other mode of treatment, he recommends fomentations to be made with warm water, and, after that, an application of cabbage, beaten up, to the parts affected, twice a-day. He says, also, that fistulas and sprains should be treated in a similar way, as well as all humours which it may be desirable to bring to a head and disperse; and he states that this vegetable, boiled and eaten fasting, in considerable quantities, with oil and salt, has the effect of preventing dreams and wakefulness; also, that if, after one boiling, it is boiled a second time, with the addition of oil, salt, cummin, and polenta, it will relieve gripings in the stomach; and that, if eaten

in this way without bread, it is more beneficial still. Among various other particulars, he says, that if taken in drink with black wine, it has the effect of carrying off the bilious secretions; and he recommends the urine of a person who has been living on a cabbage diet to be preserved, as, when warmed, it is a good remedy for diseases of the sinews. I will, however, here give the identical words in which Cato expresses himself upon this point: "If you wash little children with this urine," says he, "they will never be weak and puny."

He recommends, also, the warm juice of cabbage to be injected into the ears, in combination with wine, and assures us that it is a capital remedy for deafness: and he says that the cabbage is a cure for impetigo without the formation of ulcers.

CHAP. 34.

PINIONS OF THE GREEKS RELATIVE THERETO.

As we have already given those of Cato, it will be as well to set forth the opinions entertained by the Greek writers on this subject, only in relation, however, to those points upon which he has omitted to touch. They are of opinion that cabbage, not thoroughly boiled, carries off the bile, and has the effect of loosening the bowels; while, on the other hand, if it is boiled twice over, it will act as an astringent. They say, too, that as there is a natural enmity between it and the vine, it combats the effects of wine; that, if eaten before drinking, it is sure to prevent drunkenness, being equally a dispellent of crapulence if taken after drinking; that cabbage is a food very beneficial to the eyesight, and that the juice of it raw is even more so, if the corners of the eyes are only touched with a mixture of it with Attic honey. Cabbage, too, according to the same testimony, is extremely easy of digestion, and, as an aliment, greatly tends to clear the senses.

The school of Erasistratus proclaims that there is nothing more beneficial to the stomach and the sinews than cabbage; for which reason, he says, it ought to be given to the paralytic and nervous, as well as to persons affected with spitting of blood. Hippocrates prescribes it, twice boiled, and eaten with salt, for dysentery and cœliac affections, as also for tenesmus and diseases of the kidneys; he is of opinion, too, that, as an aliment, it increases the quantity of the milk in women who are nursing, and that it promotes the menstrual discharge. The stalk, too, eaten raw, is efficacious in expelling the dead foetus. Apollodorus prescribes the seed or else the juice of the cabbage to be taken in cases of poisoning by fungi; and Philistion recommends the juice for persons affected with opisthotony, in goats'-milk, with salt and honey.

I find, too, that persons have been cured of the gout by eating cabbage and drinking a decoction of that plant. This decoction has been given, also, to persons afflicted with the cardiac disease and epilepsy, with the addition of salt; and it has been administered in white wine, for affections of the spleen, for a period of forty days.

According to Philistion, the juice of the raw root should be given as a gargle to persons afflicted with icterus or phrenitis, and for hiccup he prescribes a mixture of it, in vinegar, with coriander, anise, honey, and pepper. Used as a liniment, cabbage, he says, is beneficial for inflations of the stomach; and the very water, even, in which it has been boiled, mixed with barley-meal, is a remedy for the stings of serpents and foul ulcers of long standing; a result which is equally effected by a mixture of cabbage-juice with vinegar or fenugreek. It is in this manner, too, that some persons employ it topically, for affections of the joints and for gout. Applied topically, cabbage is a cure for epinyetis, and all kinds of spreading eruptions on the body, as

also for sudden attacks of dimness; indeed, if eaten with vinegar, it has the effect of curing the last. Applied by itself, it heals contusions and other livid spots; and mixed with a hall of alum in vinegar, it is good as a liniment for leprosy and itch-scabs: used in this way, too, it prevents the hair from falling off.

Epicharmus assures us that, applied topically, cabbage is extremely beneficial for diseases of the testes and genitals, and even better still when employed with bruised beans; he says, too, that it is a cure for convulsions; that, in combination with rue, it is good for the burning heats of fever and maladies of the stomach; and that, with rue-seed, it brings away the after-birth. It is of use, also, for the bite of the shrew-mouse. Dried cabbage-leaves, reduced to a powder, are a cathartic both by vomit and by stool.

[Detailed table of contents](#)

CHAP. 35.

CABBAGE-SPROUTS.

In all varieties of the cabbage, the part most agreeable to the taste is the cyma, although no use is made of it in medicine, as it is difficult to digest, and by no means beneficial to the kidneys. At the same time, too, it should not be omitted, that the water in which it has been boiled, and which is so highly praised for many purposes, gives out a very bad smell when poured upon the ground. The ashes of dried cabbage-stalks are generally reckoned among the caustic substances: mixed with stale grease, they are employed for sciatica, and, used as a liniment, in the form of a depilatory, together with silphium and vinegar, they prevent hair that has been once removed from growing again. These ashes, too, are taken lukewarm in oil, or else by themselves, for convulsions, internal ruptures, and the effects of falls with violence.

And are we to say then that the cabbage is possessed of no evil qualities whatever? Certainly not, for the same authors tell us, that it is apt to make the breath smell, and that it is injurious to the teeth and gums. In Egypt, too, it is never eaten, on account of its extreme bitterness.

Detailed table of contents

CHAP. 36.

THE WILD CABBAGE: THIRTY-SEVEN REMEDIES.

Cato extols infinitely more highly the properties of wild or erratic cabbage; so much so, indeed, as to affirm that the very powder of it, dried and collected in a scent-box, has the property, on merely smelling at it, of removing maladies of the nostrils and the bad smells resulting therefrom. Some persons call this wild cabbage “petræa:” it has an extreme antipathy to wine, so much so, indeed, that the vine invariably avoids it, and if it cannot make its escape, will be sure to die. This vegetable has leaves of uniform shape, small, rounded, and smooth: bearing a strong resemblance to the cultivated cabbage, it is whiter, and has a more downy leaf.

According to Chrysippus, this plant is a remedy for flatulency, melancholy, and recent wounds, if applied with honey, and not taken off before the end of six days: beaten up in water, it is good also for scrofula and fistula. Other writers, again, say that it is an effectual cure for spreading sores on the body, known as “nomæ;” that it has the property, also, of removing excrescences, and of reducing the scars of wounds and sores; that if chewed raw with honey, it is a cure for ulcers of the mouth and tonsils; and that a decoction of it used as a gargle with honey, is productive of the same effect. They say, too, that, mixed in strong vinegar with alum, in the proportion of three parts to two of alum, and then applied as a liniment, it is a cure for itch-scabs and leprous sores of long standing. Epicharmus informs us, that for the bite of a mad dog, it is quite sufficient to apply it topically to the part affected, but that if used with silphium and strong vinegar, it is better still: he says, too, that it will kill a dog, if given to it with flesh to eat.

The seed of this plant, parched, is remedial in cases of poisoning, by the stings of serpents, eating fungi, and drinking bulls’ blood. The leaves of it, either boiled and taken in the food or else eaten raw, or applied with a liniment of sulphur and nitre, are good for affections of the spleen, as well as hard tumours of the mamillæ. In swelling of the uvula, if the parts affected are only touched with the ashes of the root, a cure will be the result; and applied topically with honey, they are equally beneficial for reducing swellings of the parotid glands, and curing the stings of serpents. We will add only one more proof of the virtues of the cabbage, and that a truly marvellous one — in all vessels in which water is boiled, the incrustations which adhere with such tenacity that it is otherwise impossible to detach them, will fall off immediately if a cabbage is boiled therein.

CHAP. 37.

THE LAPSANA: ONE REMEDY.

Among the wild cabbages, we find also the lapsana, a plant which grows a foot in height, has a hairy leaf, and strongly resembles mustard, were it not that the blossom is whiter. It is eaten cooked, and has the property of soothing and gently relaxing the bowels.

Detailed table of contents

CHAP. 38.

THE SEA-CABBAGE: ONE REMEDY.

Sea-cabbage is the most strongly purgative of all these plants. It is cooked, in consequence of its extreme pungency, with fat meat, and is extremely detrimental to the stomach.

[Detailed table of contents](#)

CHAP. 39.

THE SQUILL: TWENTY-THREE REMEDIES.

In medicine, we give the name of white squill to the male plant, and of black to the female: the whiter the squill, the better it is for medicinal purposes. The dry coats being first taken off of it, the remaining part, or so much of it as retains life, is cut into pieces, which are then strung and suspended on a string, at short distances from each other. After these pieces are thoroughly dried, they are thrown into a jar of the very strongest vinegar, suspended in such a way, however, as not to touch any portion of the vessel. This is done forty-eight days before the summer solstice. The mouth of the jar is then tightly sealed with plaster; after which it is placed beneath some tiles which receive the rays of the sun the whole day through. At the end of forty-eight days the vessel is removed, the squills are taken out of it, and the vinegar poured into another jar.

This vinegar has the effect of sharpening the eyesight, and, taken every other day, is good for pains in the stomach and sides: the strength of it, however, is so great, that if taken in too large a quantity, it will for some moments produce all the appearance of death. Squills, too, if chewed by themselves even, are good for the gums and teeth; and taken in vinegar and honey they expel tapeworm and other intestinal worms. Put fresh beneath the tongue, they prevent persons afflicted with dropsy from experiencing thirst.

Squills are cooked in various ways; either in a pot with a lining of clay or grease, which is put into an oven or furnace, or else cut into pieces and stewed in a saucepan. They are dried also in a raw state, and then cut into pieces and boiled with vinegar; in which case, they are employed as a liniment for the stings of serpents. Sometimes, again, they are roasted and then cleaned; after which, the middle of the bulb is boiled again in water.

When thus boiled, they are used for dropsy, as a diuretic, being taken in doses of three oboli, with oxymel: they are employed also in a similar manner for affections of the spleen, and of the stomach, when it is too weak to digest the food, provided no ulcerations have made their appearance; also for gripings of the bowels, jaundice, and inveterate cough, accompanied with asthma. A cataplasm of squill leaves, taken off at the end of four days, has the effect of dispersing scrofulous swellings of the neck; and a decoction of squills in oil, applied as a liniment, is a cure for dandriff and running ulcers of the head.

Squills are boiled with honey also for the table, with the view of aiding the digestion more particularly; used in this way, too, they act upon the inside as a purgative. Boiled with oil, and then mixed with resin, they are a cure for chaps on the feet; and the seed, mixed with honey, is applied topically, for the cure of lumbago. Pythagoras says that a squill, suspended at the threshold of

the door, effectually shuts all access to evil spells and incantations.

Detailed table of contents

CHAP. 40.

BULBS: THIRTY REMEDIES.

Bulbs, steeped in vinegar and sulphur, are good for the cure of wounds in the face; beaten up and used alone, they are beneficial for contractions of the sinews, mixed with wine, for porrigo, and used with honey, for the bites of dogs; in this last case, however, Erasistratus says that they ought to be mixed with pitch. The same author states that, applied topically with honey, they stanch the flowing of blood; other writers say, however, that in cases of bleeding at the nose, coriander and meal should be employed in combination with them. Theodorus prescribes bulbs in vinegar for the cure of lichens, and for eruptions in the head he recommends bulbs mixed with astringent wine, or an egg beaten up; he treats defluxions of the eyes also with bulbs, applied topically, and uses a similar method for the cure of ophthalmia. The red bulbs more particularly, will cause spots in the face to disappear, if rubbed upon them with honey and nitre in the sun: and applied with wine or boiled cucumber they will remove freckles. Used either by themselves, or as Damion recommends, in combination with honied wine, they are remarkably efficacious for the cure of wounds, care being taken, however, not to remove the application till the end of four days. The same author prescribes them, too, for the cure of fractured ears, and collections of crude humours in the testes.

For pains in the joints, bulbs are used with meal; boiled in wine, and applied to the abdomen, they reduce hard swellings of the viscera. In dysentery, they are given in wine mixed with rain water; and for convulsions of the intestines they are employed, in combination with silphium, in pills the size of a bean: bruised, they are employed externally, for the purpose of checking perspiration. Bulbs are good, too, for the sinews, for which reason it is that they are given to paralytic patients. The red bulb, mixed with honey and salt, heals sprains of the feet with great rapidity. The bulbs of Megara act as a strong aphrodisiac, and garden bulbs, taken with boiled must or raisin wine, aid delivery.

Wild bulbs, made up into pills with silphium, effect the cure of wounds and other affections of the intestines. The seed, too, of the cultivated kinds is taken in wine as a cure for the bite of the phalangium, and the bulbs themselves are applied in vinegar for the cure of the stings of serpents. The ancients used to give bulb-seed to persons afflicted with madness, in drink. The blossom, beaten up, removes spots upon the legs, as well as scorches produced by fire. Diodes is of opinion that the sight is impaired by the use of bulbs; he adds, too, that when boiled they are not so wholesome as roasted, and that, of whatever nature they may be, they are difficult of digestion.

CHAP. 41.

BULBINE; ONE REMEDY. BULB EMETIC.

The Greeks give the name bulbine to a plant with leaves resembling those of the leek, and a red bulbous root. This plant, it is said, is marvellously good for wounds, but only when they are of recent date. The bulbous plant known as the “emetic” bulb, from the effects which it produces, has dark leaves, and longer than those of the other kinds.

Detailed table of contents

CHAP. 42. (10.)

GARDEN ASPARAGUS; WITH THE NEXT TWENTY-FOUR REMEDIES.

Asparagus is said to be extremely wholesome as an aliment to the stomach. With the addition of cummin, it dispels flatulency of the stomach and colon; it sharpens the eyesight also, acts as a mild aperient upon the stomach, and, boiled with wine, is good for pains in the chest and spine, and diseases of the intestines. For pains in the loins and kidneys asparagus- seed is administered in doses of three oboli, taken with an equal proportion of cummin-seed. It acts as an aphrodisiac, and is an extremely useful diuretic, except that it has a tendency to ulcerate the bladder.

The root, also, pounded and taken in white wine, is highly extolled by some writers, as having the effect of disengaging calculi, and of soothing pains in the loins and kidneys; there are some persons, too, who administer this root with sweet wine for pains in the uterus. Boiled in vinegar the root is very beneficial in cases of elephantiasis. It is said that if a person is rubbed with asparagus beaten up in oil, he will never be stung by bees.

[Detailed table of contents](#)

CHAP. 43.

CORRUDA, LIBYCUM, OR ORMINUM.

Wild asparagus is by some persons called “corruda,” by others “libycum,” and by the people of Attica “orminus.” For all the affections above enumerated it is more efficacious even than the cultivated kind, that which is white more particularly. This vegetable has the effect of dispelling the jaundice, and a decoction of it, in doses of one hemina, is recommended as an aphrodisiac; a similar effect is produced also by a mixture of asparagus seed and dill in doses of three oboli respectively. A decoction of asparagus juice is given also for the stings of serpents; and the root of it, mixed with that of marathrum, is reckoned in the number of the most valuable remedies we are acquainted with.

In cases of hæmaturia, Chrysippus recommends a mixture of asparagus, parsley, and cummin seed, to be given to the patient every five days, in doses of three oboli, mixed with two cyathi of wine. He says, however, that though employed this way, it is a good diuretic, it is bad for dropsy, and acts as an antaphrodisiac; and that it is injurious to the bladder, unless it is boiled first. He states also, that if the water in which it is boiled is given to dogs, it will kill them; and that the juice of the root boiled in wine, kept in the mouth, is an effectual cure for tooth-ache.

Detailed table of contents

CHAP. 44. (11.)

PARSLEY; SEVENTEEN REMEDIES.

Parsley is held in universal esteem; for we find sprigs of it swimming in the draughts of milk given us to drink in country-places; and we know that as a seasoning for sauces, it is looked upon with peculiar favour. Applied to the eyes with honey, which must also be fomented from time to time with a warm decoction of it, it has a most marvellous efficacy in cases of defluxion of those organs or of other parts of the body; as also when beaten up and applied by itself, or in combination with bread or with polenta. Fish, too, when found to be in an ailing state in the preserves, are greatly refreshed by giving them green parsley. As to the opinions entertained upon it among the learned, there is not a single production dug out of the earth in reference to which a greater diversity exists.

Parsley is distinguished as male and female: according to Chrysippus, the female plant has a hard leaf and more curled than the other, a thick stem, and an acrid, hot taste. Dionysius says, that the female is darker than the other kind, has a shorter root, and engenders small worms. Both of these writers, however, agree in saying that neither kind of parsley should be admitted into the number of our aliments; indeed, they look upon it as nothing less than sacrilege to do so, seeing that parsley is consecrated to the funereal feasts in honour of the dead. They say, too, that it is injurious to the eyesight, that the stalk of the female plant engenders small worms, for which reason it is that those who eat of it become barren — males as well as females; and that children suckled by females who live on a parsley diet, are sure to be epileptic. They agree, however, in stating that the male plant is not so injurious in its effects as the female, and that it is for this reason that it is not absolutely condemned and classed among the forbidden plants. The leaves of it, employed as a cataplasm, are used for dispersing hard tumours in the mamillæ; and when boiled in water, it makes it more agreeable to drink. The juice of the root more particularly, mixed with wine, allays the pains of lumbago, and, injected into the ears, it diminishes hardness of hearing. The seed of it acts as a diuretic, promotes the menstrual discharge, and brings away the afterbirth.

Bruises and livid spots, if fomented with a decoction of parsley-seed, will resume their natural colour. Applied topically, with the white of egg, or boiled in water, and then drunk, it is remedial for affections of the kidneys; and beaten up in cold water it is a cure for ulcers of the mouth. The seed, mixed with wine, or the root, taken with old wine, has the effect of breaking calculi in the bladder. The seed, too, is given in white wine, to persons afflicted with the jaundice.

CHAP. 45.

APIASTRUM, OR MELISSOPHYLLUM.

Hyginus gave the name of “apiastrum” to melissophyllum: but that which grows in Sardinia is poisonous, and universally condemned. I speak here of this plant, because I feel it my duty to place before the reader every object which has been classified, among the Greeks, under the same name.

Detailed table of contents

CHAP. 46.

OLUSATRUM OR HIPPOSELINON; ELEVEN REMEDIES. OREOSELINON; TWO REMEDIES. HELIOSELINON; ONE REMEDY.

Olusatrum, usually known as hipposelinon, is particularly repulsive to scorpions. The seed of it, taken in drink, is a cure for gripings in the stomach and intestinal complaints, and a decoction of the seed, drunk in honied wine, is curative in cases of dysuria. The root of the plant, boiled in wine, expels calculi of the bladder, and is a cure for lumbago and pains in the sides. Taken in drink and applied topically, it is a cure for the bite of a mad dog, and the juice of it, when drunk, is warming for persons benumbed with cold.

Some persons make out oreoselinon to be a fourth species of parsley: it is a shrub about a palm in height, with an elongated seed, bearing a strong resemblance to that of cummin, and efficacious for the urine and the catamenia. Helioselinon is possessed of peculiar virtues against the bites of spiders: and oreoselinon is used with wine for promoting the menstrual discharge.

Detailed table of contents

CHAP. 47. (12.)

PETROSELINON; ONE REMEDY. BUSELINON; ONE REMEDY.

Another kind again, which grows in rocky places, is known by some persons as “petroselinon:” it is particularly good for abscesses, taken in doses of two spoonfuls of the juice to one cyathus of juice of horehound, mixed with three cyathi of warm water. Some writers have added buselinon to the list, which differs only from the cultivated kind in the shortness of the stalk and the red colour of the root, the medicinal properties being just the same. Taken in drink or applied topically, it is an excellent remedy for the stings of serpents.

[Detailed table of contents](#)

CHAP. 48.

OCIMUM; THIRTY-FIVE REMEDIES.

Chrysippus has exclaimed as strongly, too, against ocimum as he has against parsley, declaring that it is prejudicial to the stomach and the free discharge of the urine, and is injurious to the sight; that it produces insanity, too, and lethargy, as well as diseases of the liver; and that it is for this reason that goats refuse to touch it. Hence he comes to the conclusion, that the use of it ought to be avoided by man. Some persons go so far as to say, that if beaten up, and then placed beneath a stone, a scorpion will breed there; and that if chewed, and then placed in the sun, worms will breed in it. The people of Africa maintain, too, that if a person is stung by a scorpion the same day on which he has eaten ocimum, his life cannot possibly be saved. Even more than this, there are some who assert, that if a handful of ocimum is beaten up with ten sea or river crabs, all the scorpions in the vicinity will be attracted to it. Diodotus, too, in his Book of Recipes, says, that ocimum, used as an article of food, breeds lice.

Succeeding ages, again, have warmly defended this plant; it has been maintained, for instance, that goats do eat it, that the mind of no one who has eaten of it is at all affected, and, that mixed with wine, with the addition of a little vinegar, it is a cure for the stings of land scorpions, and the venom of those found in the sea. Experience has proved, too, that the smell of this plant in vinegar is good for fainting fits and lethargy, as well as inflammations; that employed as a cooling liniment, with rose oil, myrtle oil, or vinegar, it is good for headache; and that applied topically with wine, it is beneficial for defluxions of the eyes. It has been found also, that it is good for the stomach; that taken with vinegar, it dispels flatulent eructations; that applications of it arrest fluxes of the bowels; that it acts as a diuretic, and that in this way it is good for jaundice and dropsy, as well as cholera and looseness of the bowels.

Hence it is that Philistio has prescribed it even for cœliac affections, and boiled, for dysentery. Some persons, too, though contrary to the opinion of Plistonicus, have given it in wine for tenesmus and spitting of blood, as also for obstructions of the viscera. It is employed, too, as a liniment for the mamillæ, and has the effect of arresting the secretion of the milk. It is very good also for the ears of infants, when applied with goose-grease more particularly. The seed of it, beaten up, and inhaled into the nostrils, is provocative of sneezing, and applied as a liniment to the head, of running at the nostrils: taken in the food, too, with vinegar, it purges the uterus. Mixed with copperas it removes warts. It acts, also, as an aphrodisiac, for which reason it is given to horses and asses at the season for covering.

(13.) Wild ocimum has exactly the same properties in every respect, though in a more active degree. It is particularly good, too, for the various

affections produced by excessive vomiting, and for abscesses of the womb. The root, mixed with wine, is extremely efficacious for bites inflicted by wild beasts.

Detailed table of contents

CHAP. 49.

ROCKET: TWELVE REMEDIES.

The seed of rocket is remedial for the venom of the scorpion and the shrew-mouse: it repels, too, all parasitical insects which breed on the human body, and applied to the face, as a liniment, with honey, removes spots upon the skin. Used with vinegar, too, it is a cure for freckles; and mixed with ox-gall it restores the livid marks left by wounds to their natural colour. It is said that if this plant is taken in wine by persons who are about to undergo a flogging, it will impart a certain degree of insensibility to the body. So agreeable is its flavour as a savouring for food, that the Greeks have given it the name of “euzomon.” It is generally thought that rocket, lightly bruised, and employed as a fomentation for the eyes, will restore the sight to its original goodness, and that it allays coughs in young infants. The root of it, boiled in water, has the property of extracting the splinters of broken bones.

As to the properties of rocket as an aphrodisiac, we have mentioned them already. Three leaves of wild rocket plucked with the left hand, beaten up in hydromel, and then taken in drink, are productive of a similar effect.

Detailed table of contents

CHAP. 50.

NASTURTIIUM: FORTY-TWO REMEDIES.

Nasturtium, on the other hand, is an antiaphrodisiac; it has the effect also of sharpening the senses, as already stated. There are two varieties of this plant: one of them is purgative, and, taken in doses of one denarius to seven of water, carries off the bilious secretions. Applied as a liniment to scrofulous sores, with bean-meal, and then covered with a cabbage-leaf, it is a most excellent remedy. The other kind, which is darker than the first, has the effect of carrying off vicious humours of the head, and sharpening the sight: taken in vinegar it calms the troubled spirits, and, drunk with wine or taken in a fig, it is good for affections of the spleen; taken in honey, too, fasting daily, it is good for a cough. The seed of it, taken in wine, expels all kinds of intestinal worms, and with the addition of wild mint, it acts more efficaciously still. It is good, too, for asthma and cough, in combination with wild marjoram and sweet wine; and a decoction of it in goats' milk is used for pains in the chest. Mixed with pitch it disperses tumours, and extracts thorns from the body; and, employed as a liniment, with vinegar, it removes spots upon the body. When used for the cure of carcinoma, white of eggs is added to it. With vinegar it is employed also as a liniment for affections of the spleen, and with honey it is found to be very useful for the complaints of infants.

Sextius adds, that the smell of burnt nasturtium drives away serpents, neutralizes the venom of scorpions, and gives relief in head-ache; with the addition too, of mustard, he says, it is a cure for alopecia, and applied to the ears with a fig, it is a remedy for hardness of hearing. The juice of it, he says, if injected into the ears, will effect the cure of tooth-ache, and employed with goose-grease it is a remedy for porrigo and ulcerous sores of the head. Applied with leaven it brings boils to a head, and makes carbuncles suppurate and break: used with honey, too, it is good for cleansing phagedænic ulcers. Topical applications are made of it, combined with vinegar and polenta, in cases of sciatica and lumbago: it is similarly employed, too, for lichens and malformed nails, its qualities being naturally caustic. The best nasturtium of all is that of Babylonia; the wild variety possesses the same qualities as the cultivated in every respect, but in a more powerful degree.

[Detailed table of contents](#)

CHAP. 51.

RUE: EIGHTY-FOUR REMEDIES.

One of the most active, however, of all the medicinal plants, is rue. The cultivated kind has broader leaves and more numerous branches than the other. Wild rue is more violent in its effects, and more active in every respect. The juice of it is extracted by beating it up, and moistening it moderately with water; after which it is kept for use in boxes of Cyprian copper. Given in large doses, this juice has all the baneful effects of poison, and that of Macedonia more particularly, which grows on the banks of the river Aliac- mon. It is a truly wonderful thing, but the juice of hemlock has the property of neutralizing its effects. Thus do we find one thing acting as the poison of another poison, for the juice of hemlock is very beneficial, rubbed upon the hands and [face] of persons employed in gathering rue.

In other respects, rue is one of the principal ingredients employed in antidotes, that of Galatia more particularly. Every species of rue, employed by itself, has the effect also of an antidote, if the leaves are bruised and taken in wine. It is good more particularly in cases of poisoning by wolf's bane and mistletoe, as well as by fungi, whether administered in the drink or the food. Employed in a similar manner, it is good for the stings of serpents; so much so, in fact, that weasels, when about to attack them, take the precaution first of protecting themselves by eating rue. Rue is good, too, for the injuries by scorpions and spiders, the stings of bees, hornets, and wasps, the noxious effects produced by cantharides and salamanders, and the bites of mad dogs. The juice is taken in doses of one acetabulum, in wine; and the leaves, beaten up or else chewed, are applied topically, with honey and salt, or boiled with vinegar and pitch. It is said that people rubbed with the juice of rue, or even having it on their person, are never attacked by these noxious creatures, and that serpents are driven away by the stench of burning rue. The most efficacious, however, of all, is the root of wild rue, taken with wine; this too, it is said, is more beneficial still, if drunk in the open air.

Pythagoras has distinguished this plant also into male and female, the former having smaller leaves than the other, and of a grass-green colour; the female plant, he says, has leaves of a larger size and a more vivid hue. The same author, too, has considered rue to be injurious to the eyes; but this is an error, for engravers and painters are in the habit of eating it with bread, or else nasturtium, for the benefit of the sight; wild goats, too, eat it for the sight, they say. Many persons have dispersed films on the eyes by rubbing them with a mixture of the juice of rue with Attic honey, or the milk of a woman just delivered of a male child: the same result has been produced also by touching the corners of the eyes with the pure juice of the plant. Applied topically, with polenta, rue carries off defluxions of the eyes; and, taken with wine, or applied

topically with vinegar and rose oil, it is a cure for head-ache. If, however, the pain attacks the whole of the head, the rue should be applied with barley-meal and vinegar. This plant has the effect also of dispelling crudities, flatulency, and inveterate pains of the stomach; it opens the uterus, too, and restores it when displaced; for which purpose it is applied as a liniment, with honey, to the whole of the abdomen and chest. Mixed with figs, and boiled down to one half, it is administered in wine for dropsy; and it is taken in a similar manner for pains of the chest, sides, and loins, as well as for coughs, asthma, and affections of the lungs, liver, and kidneys, and for shivering fits. Persons about to indulge in wine, take a decoction of the leaves, to prevent head-ache and surfeit. Taken in food, too, it is wholesome, whether eaten raw or boiled, or used as a confection: boiled with hyssop, and taken with wine, it is good for gripings of the stomach. Employed in the same way, it arrests internal hæmorrhage, and, applied to the nostrils, bleeding at the nose: it is beneficial also to the teeth if rinsed with it. In cases of ear-ache, this juice is injected into the ears, care being taken to moderate the dose, as already stated, if wild rue is employed. For hardness of hearing, too, and singing in the ears, it is similarly employed in combination with oil of roses, or oil of laurel, or else cummin and honey.

Juice of rue pounded with vinegar, is applied also to the temples and the region of the brain in persons affected with phrenitis; some persons, however, have added to this mixture wild thyme and laurel leaves, rubbing the head and neck as well with the liniment. It has been given in vinegar to lethargic patients to smell at, and a decoction of it is administered for epilepsy, in doses of four cyathi, as also just before the attacks in fever of intolerable chills. It is likewise given raw to persons for shivering fits. Rue is a provocative of the urine to bleeding even: it promotes the menstrual discharge, also, and brings away the after-birth, as well as the dead foetus even, according to Hippocrates, if taken in sweet red wine. The same author, also, recommends applications of it, as well as fumigations, for affections of the uterus.

For cardiac diseases, Dioscorides prescribes applications of rue, in combination with vinegar, honey, and barley-meal: and for the iliac passion, he says that it should be mixed with meal, boiled in oil, and spread upon the wool of a sheep's fleece. Many persons recommend, for purulent expectorations, two drachmæ of dried rue to one and a half of sulphur; and, for spitting of blood, a decoction of three sprigs in wine. It is given also in dysentery, with cheese, the rue being first beaten up in wine; and it has been prescribed, pounded with bitumen, as a potion for habitual shortness of breath. For persons suffering from violent falls, three ounces of the seed is recommended. A pound of oil, in which rue leaves have been boiled, added to one sextarius of wine, forms a liniment for parts of the body which are frost-bitten. If rue really is a diuretic, as Hippocrates thinks, it is a singular thing that some persons should give it, as being an anti-diuretic, for the suppression of incontinence of urine.

Applied topically, with honey and alum, it cures itch-scabs, and leprous

sores; and, in combination with nightshade and hogs'-lard, or beef-suet, it is good for morpew, warts, scrofula, and maladies of a similar nature. Used with vinegar and oil, or else white lead, it is good for erysipelas; and, applied with vinegar, for carbuncles. Some persons prescribe silphium also as an ingredient in the liniment; but it is not employed by them for the cure of the pustules known as epinyctis. Boiled rue is recommended, also, as a cataplasm for swellings of the mamillæ, and, combined with wax, for eruptions of pituitous matter. It is applied with tender sprigs of laurel, in cases of defluxion of the testes; and it exercises so peculiar an effect upon those organs, that old rue, it is said, employed in a liniment, with axle-grease, is a cure for hernia. The seed pounded, and applied with wax, is remedial also for broken limbs. The root of this plant, applied topically, is a cure for effusion of blood in the eyes, and, employed as a liniment, it removes scars or spots on all parts of the body.

Among the other properties which are attributed to rue, it is a singular fact, that, though it is universally agreed that it is hot by nature, a bunch of it, boiled in rose-oil, with the addition of an ounce of aloes, has the effect of checking the perspiration in those who rub themselves with it; and that, used as an aliment, it impedes the generative functions. Hence it is, that it is so often given in cases of spermatorrhœa, and where persons are subject to lascivious dreams. Every precaution should be taken by pregnant women to abstain from rue as an article of diet, for I find it stated that it is productive of fatal results to the fœtus.

Of all the plants that are grown, rue is the one that is most generally employed for the maladies of cattle, whether arising from difficulty of respiration, or from the stings of noxious creatures — in which cases it is injected with wine into the nostrils — or whether they may happen to have swallowed a horse-leech, under which circumstances it is administered in vinegar. In all other maladies of cattle, the rue is prepared just as for man in a similar case.

Detailed table of contents

CHAP. 52. (14.)

WILD MINT: TWENTY REMEDIES.

Mentastrum, or wild mint, differs from the other kind in the appearance of the leaves, which have the form of those of ocimum and the colour of pennyroyal; for which reason, some persons, in fact, give it the name of wild pennyroyal. The leaves of this plant, chewed and applied topically, are a cure for elephantiasis; a discovery which was accidentally made in the time of Pompeius Magnus, by a person affected with this malady covering his face with the leaves for the purpose of neutralizing the bad smell that arose therefrom. These leaves are employed also as a liniment, and in drink, with a mixture of salt, oil, and vinegar, for the stings of scorpions; and, in doses of two drachmæ to two cyathi of wine, for those of scolopendræ and serpents. A decoction, too, of the juice is given for the sting of the scolopendra. Leaves of wild mint are kept, dried and reduced to a fine powder, as a remedy for poisons of every description. Spread on the ground or burnt, this plant has the effect of driving away scorpions.

Taken in drink, wild mint carries off the lochia in females after parturition; but, if taken before, it is fatal to the fœtus. It is extremely efficacious in cases of rupture and convulsions, and, though in a somewhat less degree, for orthopnœa, gripings of the bowels, and cholera: it is good, too, as a topical application for lumbago and gout. The juice of it is injected into the ears for worms breeding there; it is taken also for jaundice, and is employed in liniments for scrofulous sores. It prevents the recurrence of lascivious dreams; and taken in vinegar, it expels tape-worm. For the cure of porrigo, it is put in vinegar, and the head is washed with the mixture in the sun.

Detailed table of contents

CHAP. 53.

MINT: FORTY-ONE REMEDIES.

The very smell of mint reanimates the spirits, and its flavour gives a remarkable zest to food: hence it is that it is so generally an ingredient in our sauces. It has the effect of preventing milk from turning sour, or curdling and thickening; hence it is that it is so generally put into milk used for drinking, to prevent any danger of persons being choked by it in a curdled state. It is administered also for this purpose in water or honied wine. It is generally thought, too, that it is in consequence of this property that it impedes generation, by preventing the seminal fluids from obtaining the requisite consistency. In males as well as females it arrests bleeding, and it has the property, with the latter, of suspending the menstrual discharge. Taken in water, with amyllum, it prevents looseness in cœliac complaints. Syriation employed this plant for the cure of abscesses of the uterus, and, in doses of three oboli, with honied wine, for diseases of the liver: he prescribed it also, in pottage, for spitting of blood. It is an admirable remedy for ulcerations of the head in children, and has the effect equally of drying the trachea when too moist, and of bracing it when too dry. Taken in honied wine and water, it carries off purulent phlegm.

The juice of mint is good for the voice when a person is about to engage in a contest of eloquence, but only when taken just before. It is employed also with milk as a gargle for swelling of the uvula, with the addition of rue and coriander. With alum, too, it is good for the tonsils of the throat, and, mixed with honey, for roughness of the tongue. Employed by itself, it is a remedy for internal convulsions and affections of the lungs. Taken with pomegranate juice, as Democritus tells us, it arrests hiccup and vomiting. The juice of mint fresh gathered, inhaled, is a ready for affections of the nostrils. Beaten up and taken in vinegar, mint is a cure for cholera, and for internal fluxes of blood: applied externally, with polenta, it is remedial for the iliac passion and tension of the mamillæ. It is applied, too, as a liniment to the temples for head-ache; and it is taken internally, as an antidote for the stings of scolopendræ, sea-scorpions, and serpents. As a liniment it is applied also for defluxions of the eyes, and all eruptions of the head, as well as maladies of the rectum.

Mint is an effectual preventive, too, of chafing of the skin, even if held in the hand only. In combination with honied wine, it is employed as an injection for the ears. It is said, too, that this plant will cure affections of the spleen, if tasted in the garden nine days consecutively, without plucking it, the person who bites it saying at the same moment that he does so for the benefit of the spleen: and that, if dried, and reduced to powder, a pinch of it with three fingers taken in water, will cure stomach-ache. Sprinkled in this form in drink, it is said to have the effect of expelling intestinal worms.

Detailed table of contents

CHAP. 54.

PENNYROYAL: TWENTY-FIVE REMEDIES.

Pennyroyal partakes with mint, in a very considerable degree, the property of restoring consciousness in fainting fits; slips of both plants being kept for the purpose in glass bottles filled with vinegar. It is for this reason that Varro has declared that a wreath of pennyroyal is more worthy to grace our chambers than a chaplet of roses: indeed, it is said that, placed upon the head, it materially alleviates head-ache. It is generally stated, too, that the smell of it alone will protect the head against the injurious effects of cold or heat, and that it acts as a preventive of thirst; also, that persons exposed to the sun, if they carry a couple of sprigs of pennyroyal behind the ears, will never be incommoded by the heat. For various pains, too, it is employed topically, mixed with polenta and vinegar.

The female plant is the more efficacious of the two; it has a purple flower, that of the male being white. Taken in cold water with salt and polenta it arrests nausea, as well as pains of the chest and abdomen. Taken, too, in water, it prevents gnawing pains of the stomach, and, with vinegar and polenta, it arrests vomiting. In combination with salt and vinegar, and polenta, it loosens the bowels. Taken with boiled honey and nitre, it is a cure for intestinal complaints. Employed with wine it is a diuretic, and if the wine is the produce of the Aminean grape, it has the additional effect of dispersing calculi of the bladder and removing all internal pains. Taken in conjunction with honey and vinegar, it modifies the menstrual discharge, and brings away the after-birth, restores the uterus, when displaced, to its natural position, and expels the dead foetus. The seed is given to persons to smell at, who have been suddenly struck dumb, and is prescribed for epileptic patients in doses of one cyathus, taken in vinegar. If water is found unwholesome for drinking, bruised pennyroyal should be sprinkled in it; taken with wine it modifies acridities of the body.

Mixed with salt, it is employed as a friction for the sinews, and with honey and vinegar, in cases of opisthotony. Decoctions of it are prescribed as a drink for persons stung by serpents; and, beaten up in wine, it is employed for the stings of scorpions, that which grows in a dry soil in particular. This plant is looked upon as efficacious also for ulcerations of the mouth, and for coughs. The blossom of it, fresh gathered, and burnt, kills fleas by its smell. Xenocrates, among the other remedies which he mentions, says that in tertian fevers, a sprig of pennyroyal, wrapped in wool, should be given to the patient to smell at, just before the fit comes on, or else it should be put under the bed-clothes and laid by the patient's side.

CHAP. 55.

WILD PENNYROYAL: SEVENTEEN REMEDIES.

For all the purposes already mentioned, wild pennyroyal has exactly the same properties, but in a still higher degree. It bears a strong resemblance to wild marjoram, and has a smaller leaf than the cultivated kind: by some persons it is known as “dictamnus.” When browsed upon by sheep and goats, it makes them bleat, for which reason, some of the Greeks, changing a single letter in its name, have called it “blechon,” [instead of “glechon.”]

This plant is naturally so heating as to blister the parts of the body to which it is applied. For a cough which results from a chill, it is a good plan for the patient to rub himself with it before taking the bath; it is similarly employed, too, in shivering fits, just before the attacks come on, and for convulsions and gripings of the stomach. It is also remarkably good for the gout.

To persons afflicted with spasms, this plant is administered in drink, in combination with honey and salt; and it renders expectoration easy in affections of the lungs. Taken with salt it is beneficial for the spleen and bladder, and is curative of asthma and flatulency. A decoction of it is equally as good as the juice: it restores the uterus when displaced, and is prescribed for the sting of either the land or the sea scolopendra, as well as the scorpion. It is particularly good, too, for bites inflicted by a human being. The root of it, newly taken up, is extremely efficacious for corroding ulcers, and in a dried state tends to efface the deformities produced by scars.

Detailed table of contents

CHAP. 56.

NEP: NINE REMEDIES.

Nep has also some affinity in its effects with pennyroyal. Boiled down in water to one third, these plants dispel sudden chills: they promote the menstrual discharge also in females, and allay excessive heats in summer. Nep possesses certain virtues against the stings of serpents; at the very smoke and smell of it they will instantly take to flight, and persons who have to sleep in places where they are apprehensive of them, will do well to place it beneath them. Bruised, it is employed topically for lacrymal fistulas of the eye: fresh gathered and mixed in vinegar with one third part of bread, it is applied as a liniment for head-ache. The juice of it, injected into the nostrils, with the head thrown back, arrests bleeding at the nose, and the root has a similar effect. This last is employed also, with myrtle-seed, in warm raisin wine, as a gargle for the cure of quinsy.

[Detailed table of contents](#)

CHAP. 57.

CUMMIN: FORTY-EIGHT REMEDIES. WILD CUMMIN: TWENTY-SIX REMEDIES.

Wild cummin is a remarkably slender plant, consisting of four or five leaves indented like a saw; like the cultivated kind, it is much employed in medicine, among the stomachic remedies more particularly. Bruised and taken with bread, or else drunk in wine and water, it dispels phlegm and flatulency, as well as gripings of the bowels and pains in the intestines. Both varieties have the effect, however, of producing paleness in those who drink these mixtures; at all events, it is generally stated that the disciples of Porcius Latro, so celebrated among the professors of eloquence, used to employ this drink for the purpose of imitating the paleness which had been contracted by their master, through the intensity of his studies: and that Julius Vindex, in more recent times, that assertor of our liberties against Nero, adopted this method of playing upon those who were looking out for a place in his will. Applied in the form of lozenges, or fresh with vinegar, cummin has the effect of arresting bleeding at the nose, and used by itself, it is good for defluxions of the eyes. Combined with honey, it is used also for swellings of the eyes. With children of tender age, it is sufficient to apply it to the abdomen. In cases of jaundice, it is administered in white wine, immediately after taking the bath.

(15.) The cummin of Æthiopia, more particularly, is given in vinegar and water, or else as an electuary with honey. It is thought, too, that the cummin of Africa has the peculiar property of arresting incontinence of urine. The cultivated plant is given, parched and beaten up in vinegar, for affections of the liver, as also for vertigo. Beaten up in sweet wine, it is taken in cases, also, where the urine is too acrid; and for affections of the uterus, it is administered in wine, the leaves of it being employed topically as well, in layers of wool. Parched and beaten up with honey, it is used as an application for swellings of the testes, or else with rose oil and wax.

For all the purposes above-mentioned, wild cummin is more efficacious than cultivated; as also, in combination with oil, for the stings of serpents, scorpions, and scolopendræ. A pinch of it with three fingers, taken in wine, has the effect of arresting vomiting and nausea; it is used, too, both as a drink and a liniment for the colic, or else it is applied hot, in dossils of lint, to the part affected, bandages being employed to keep it in its place. Taken in wine, it dispels hysterical affections, the proportions being three drachmæ of cummin to three cyathi of wine. It is used as an injection, too, for the ears, when affected with tingling and singing, being mixed for the purpose with veal suet or honey. For contusions, it is applied as a liniment, with honey, raisins, and vinegar, and for dark freckles on the skin with vinegar.

CHAP. 58.

AMMI: TEN REMEDIES.

There is another plant, which bears a very strong resemblance to cummin, known to the Greeks as “ammi;” some persons are of opinion, that it is the same as the Æthiopian cummin. Hippocrates gives it the epithet of “royal;” no doubt, because he looks upon it as possessed of greater virtues than Egyptian cummin. Many persons, however, consider it to be of a totally different nature from cummin, as it is so very much thinner, and of a much whiter colour. Still, it is employed for just the same purposes as cummin, for we find it used at Alexandria for putting under loaves of bread, and forming an ingredient in various sauces. It has the effect of dispelling flatulency and gripings of the bowels, and of promoting the secretion of the urine and the menstrual discharge. It is employed, also, for the cure of bruises, and to assuage defluxions of the eyes. Taken in wine with linseed, in doses of two drachmæ, it is a cure for the stings of scorpions; and, used with an equal proportion of myrrh, it is particularly good for the bite of the cerastes.

Like cummin, too, it imparts paleness of complexion to those who drink of it. Used as a fumigation, with raisins or with resin, it acts as a purgative upon the uterus. It is said, too, that if women smell at this plant during the sexual congress, the chances of conception will be greatly promoted thereby.

Detailed table of contents

CHAP. 59.

THE CAPPARIS OR CAPER: EIGHTEEN REMEDIES.

We have already spoken of the caper at sufficient length when treating of the exotic plants. The caper which comes from beyond sea should never be used; that of Italy is not so dangerous. It is said, that persons who eat this plant daily, are never attacked by paralysis or pains in the spleen. The root of it, pounded, removes white eruptions of the skin, if rubbed with it in the sun. The bark of the root, taken in wine, in doses of two drachmæ, is good for affections of the spleen; the patient, however, must forego the use of the bath. It is said, too, that in the course of thirty-five days the whole of the spleen may be discharged under this treatment, by urine and by stool. The caper is also taken in drink for lumbago and paralysis; and the seed of it boiled, and beaten up in vinegar, or the root chewed, has a soothing effect in tooth-ache. A decoction of it in oil is employed, also, as an injection for ear-ache.

The leaves and the root, fresh out of the ground, mixed with honey, are a cure for the ulcers known as phagedænic. In the same way, too, the root disperses scrofulous swellings; and a decoction of it in water removes imposthumes of the parotid glands, and worms. Beaten up and mixed with barley-meal, it is applied topically for pains in the liver; it is a cure, also, for diseases of the bladder. In combination with oxymel, it is prescribed for tapeworm, and a decoction of it in vinegar removes ulcerations of the mouth. It is generally agreed among writers that the caper is prejudicial to the stomach.

Detailed table of contents

CHAP. 60.

LIGUSTICUM, OR LOVAGE: FOUR REMEDIES.

Ligusticum, by some persons known as “panax,” is good for the stomach, and is curative of convulsions and flatulency. There are persons who give this plant the name of “cunila bubula;” but, as we have already stated, they are in error in so doing.

Detailed table of contents

CHAP. 61. (16.)

CUNILA BUBULA: FIVE REMEDIES.

In addition to garden cunila, there are numerous other varieties of it employed in medicine. That known to us as “cunila bubula,” has a very similar seed to that of pennyroyal. This seed, chewed and applied topically, is good for wounds: the plaster, however, must not be taken off till the fifth day. For the stings of serpents, this plant is taken in wine, and the leaves of it are bruised and applied to the wound; which is also rubbed with them as a friction. The tortoise, when about to engage in combat with the serpent, employs this plant as a preservative against the effects of its sting; some persons, for this reason, have given it the name of “panacea.” It has the effect also of dispersing tumours and maladies of the male organs, the leaves being dried for the purpose, or else beaten up fresh and applied to the part affected. For every purpose for which it is employed it combines remarkably well with wine.

[Detailed table of contents](#)

CHAP. 62.

CUNILA GALLINACEA, OR ORIGANUM: FIVE REMEDIES.

There is another variety, again, known to our people as “cunila gallinacea,” and to the Greeks as Heracleotic origanum. Beaten up with salt, this plant is good for the eyes; and it is a remedy for cough and affections of the liver. Mixed with meal, and taken as a broth, with oil and vinegar, it is good for pains in the side, and the stings of serpents in particular.

Detailed table of contents

CHAP. 63.

CUNILAGO: EIGHT REMEDIES.

There is a third species, also, known to the Greeks as “male cunila,” and to us as “cunilago.” This plant has a foetid smell, a ligneous root, and a rough leaf. Of all the varieties of cunila, this one, it is said, is possessed of the most active properties. If a handful of it is thrown anywhere, all the beetles in the house, they say, will be attracted to it; and, taken in vinegar and water, it is good for the stings of scorpions more particularly. It is stated, also, that if a person is rubbed with three leaves of it, steeped in oil, it will have the effect of keeping all serpents at a distance.

[Detailed table of contents](#)

CHAP. 64.

SOFT CUNILA: THREE REMEDIES. LIBANOTIS: THREE REMEDIES.

The variety, on the other hand, known as soft cunila, has a more velvety leaf, and branches covered with thorns; when rubbed it has just the smell of honey, and it adheres to the fingers when touched. There is another kind, again, known to us as “libanotis,” a name which it owes to the resemblance of its smell to that of frankincense. Both of these plants, taken in wine or vinegar, are antidotes for the stings of serpents. Beaten up in water, also, and sprinkled about a place, they kill fleas.

[Detailed table of contents](#)

CHAP. 65.

CULTIVATED CUNILA; THREE REMEDIES. MOUNTAIN CUNILA; SEVEN
REMEDIES.

Cultivated cunila has also its medicinal uses. The juice of it, in combination with rose oil, is good for the ears; and the plant itself is taken in drink, to counteract the effects of violent blows.

A variety of this plant is the mountain cunila, similar to wild thyme in appearance, and particularly efficacious for the stings of serpents. This plant is diuretic, and promotes the lochial discharge: it aids the digestion, too, in a marvellous degree. Both varieties have a tendency to sharpen the appetite, even when persons are troubled with indigestion, if taken fasting in drink: they are good, too, for sprains, and, taken with barley-meal, and vinegar and water, they are extremely useful for stings inflicted by wasps and insects of a similar nature.

We shall have occasion to speak of other varieties of libanotis in their appropriate places.

Detailed table of contents

CHAP. 66. (17.)

PIPERITIS, OR SILIQUASTRUM: FIVE REMEDIES.

Piperitis, which we have already mentioned as being called “siliquastrum,” is taken in drink for epilepsy. Castor used to give a description of it to the following effect: “The stalk of it is long and red, with the knots lying close together; the leaves are similar to those of the laurel, and the seed is white and slender, like pepper in taste.” He described it also as being beneficial to the gums and teeth, imparting sweetness to the breath, and dispelling flatulency.

[Detailed table of contents](#)

CHAP. 67.

ORIGANUM, ONITIS, OR PRASION: SIX REMEDIES.

Origanum, which, as we have already stated, rivals cunila in flavour, includes many varieties employed in medicine. Onitis, or prasion, is the name given to one of these, which is not unlike hyssop in appearance: it is employed more particularly, with warm water, for gnawing pains at the stomach, and for indigestion. Taken in white wine it is good for the stings of spiders and scorpions; and, applied with vinegar and oil, in wool, it is a cure for sprains and bruises.

[Detailed table of contents](#)

CHAP. 68.

TRAGORIGANUM: NINE REMEDIES.

Tragoriganum bears a strong resemblance to wild thyme. It is diuretic, disperses tumours, and taken in drink is extremely efficacious in cases of poisoning by mistletoe and stings by serpents. It is very good for acid eructations from the stomach, and for the thoracic organs. It is given also for a cough, with honey, as well as for pleurisy and peripneumony.

[Detailed table of contents](#)

CHAP. 69.

THREE VARIETIES OF HERACLEOTIC ORIGANUM: THIRTY REMEDIES.

Heraclium, again, comprehends three varieties; the first, which is the darkest, has broader leaves than the others, and is of a glutinous nature; the second, which has leaves of a more slender form, and not unlike sampsuchum in appearance, is by some persons called “prasion,” in preference: the third is of an intermediate nature between the other two, but is less efficacious for medicinal purposes than either. But the best kind of all is that of Crete, for it has a particularly agreeable smell; the next best being that of Smyrna, which has even a more powerful odour than the last. The Heracleotic origanum, however, known by the name of “onitis,” is the one that is the most esteemed for taking in drink.

Origanum, in general, is employed for repelling serpents; and it is given boiled to persons suffering from wounds. Taken in drink, it is diuretic; and mixed with root of panax, it is given for the cure of ruptures and convulsions. In combination with figs or hyssop, it is prescribed for dropsical patients in doses of one acetabulum, being reduced by boiling to one sixth. It is good also for the itch, prurigo, and leprosy, taken just before the bath. The juice of it is injected into the ears with milk; it being a cure, also, for affections of the tonsils and the uvula, and for ulcers of the head. A decoction of it, taken with the ashes in wine, neutralizes poison by opium or gypsum. Taken in doses of one acetabulum, it relaxes the bowels. It is applied as a liniment for bruises and for tooth-ache; and mixed with honey and nitre, it imparts whiteness to the teeth. It has the effect, also, of stopping bleeding at the nose.

A decoction of this plant, with barley-meal, is employed for imposthumes of the parotid glands; and, beaten up with nutgalls and honey, it is used for roughness of the trachea: the leaves of it, with honey and salt, are good, too, for the spleen. Boiled with vinegar and salt, and taken in small doses, it attenuates the phlegm, when very thick and black; and beaten up with oil, it is injected into the nostrils for jaundice. When persons are affected with lassitude, the body is well rubbed with it, care being taken not to touch the abdomen. Used with pitch, it is a cure for epinycitis, and, applied with a roasted fig, it brings boils to a head. Employed with oil and vinegar, and barley-meal, it is good for scrofulous swellings; and applied topically in a fig, it is a cure for pains in the sides. Beaten up, and applied with vinegar, it is employed as a liniment for bloody fluxes of the generative organs, and it accelerates the lochial discharge after child-birth.

CHAP. 70.

DITTANDER: THREE REMEDIES.

Dittander is generally considered to rank among the caustic plants. It is owing to this property that it clears the skin of the face, not, however, without excoriating it; though, at the same time, the excoriations are easily healed by employing wax and rose oil. It is owing to this property, too, that it always removes, without difficulty, leprous sores and itch-scabs, as well as the scars left by ulcers. It is said, that in cases of toothache, if this plant is attached to the arm on the suffering side, it will have the effect of drawing the pain to it.

[Detailed table of contents](#)

CHAP. 71.

GITH, OR MELANTHION: TWENTY-THREE REMEDIES.

Gith is by some Greek writers called “melanthion,” and by others “melaspermon.” That is looked upon as the best which has the most pungent odour and is the darkest in appearance. It is employed as a remedy for wounds made by serpents and scorpions: I find that for this purpose it is applied topically with vinegar and honey, and that by burning it serpents are kept at a distance. It is taken, also, in doses of one drachma for the bites of spiders. Beaten up, and smelt at in a piece of linen cloth, it is a cure for running at the nostrils; and, applied as a liniment with vinegar and injected into the nostrils, it dispels head-ache. With oil of iris it is good for defluxions and tumours of the eyes, and a decoction of it with vinegar is a cure for tooth-ache. Beaten up and applied topically, or else chewed, it is used for ulcers of the mouth, and combined with vinegar, it is good for leprous sores and freckles on the skin. Taken in drink, with the addition of nitre, it is good for hardness of breathing, and, employed as a liniment, for indurations, tumours of long standing, and suppurations. Taken several days in succession, it augments the milk in women who are nursing.

The juice of this plant is collected in the same manner as that of henbane; and, like it, if taken in too large doses, it acts as a poison, a surprising fact, seeing that the seed is held in esteem as a most agreeable seasoning for bread. The seed cleanses the eyes also, acts as a diuretic, and promotes the menstrual discharge; and not only this, but I find it stated also, that it thirty grains only are attached to the body, in a linen cloth, it will have the effect of accelerating the after-birth. It is stated, also, that beaten up in urine, it is a cure for corns on the feet; and that when burnt it kills gnats and flies with the smell.

[Detailed table of contents](#)

CHAP. 72.

ANISE: SIXTY-ONE REMEDIES.

Anise, too, one of the comparatively small number of plants that have been commended by Pythagoras, is taken in wine, either raw or boiled, for the stings of scorpions. Both green and dried, it is held in high repute, as an ingredient in all seasonings and sauces, and we find it placed beneath the under-crust of bread. Pat with bitter-almonds into the cloth strainers for filtering wine, it imparts an agreeable flavour to the wine: it has the effect, also, of sweetening the breath, and removing all bad odours from the mouth, it chewed in the morning with smyrnion and a little honey, the mouth being then rinsed with wine.

This plant imparts a youthful look to the features; and if suspended to the pillow, so as to be smelt by a person when asleep, it will prevent all disagreeable dreams. It has the effect of promoting the appetite, also — for this, too, has been made by luxury one of the objects of art, ever since labour has ceased to stimulate it. It is for these various reasons that it has received the name of “anicetum,” given to it by some.

Detailed table of contents

CHAP. 73.

WHERE THE BEST ANISE IS FOUND: VARIOUS REMEDIES DERIVED FROM THIS PLANT.

The most esteemed anise is that of Crete, and, next to it, that of Egypt. This plant is employed in seasonings to supply the place of lovage; and the perfume of it, when burnt and inhaled, alleviates headache. Evenor prescribes an application of the root, pounded, for defluxions of the eyes; and lollas employs it in a similar manner, in combination with saffron and wine, or else beaten up by itself and mixed with polenta, for violent defluxions and the extraction of such objects as have got into the eyes: applied, too, as a liniment in water, it arrests cancer of the nose. Mixed with hyssop and oxymel, and employed as a gargle, it is a cure for quinsy; and, in combination with rose oil, it is used as an injection for the ears. Parched anise purges off phlegm from the chest, and, if taken with honey, it is better still.

For a cough, beat up fifty bitter almonds, shelled, in honey, with one acetabulum of anise. Another very easy remedy, too, is to mix three drachmæ of anise with two of poppies and some honey, a piece the size of a bean being taken three times a-day. Its main excellence, however, is as a carminative; hence it is that it is so good for flatulency of the stomach, griping pains of the intestines, and cœliac affections. A decoction of it, smelt at and drunk, arrests hiccup, and a decoction of the leaves removes indigestion. A decoction of it with parsley, if applied to the nostrils, will arrest sneezing. Taken in drink, anise promotes sleep, disperses calculi of the bladder, arrests vomiting and swelling of the viscera, and acts as an excellent pectoral for affections of the chest, and of the diaphragm, where the body is tightly laced. It is beneficial, also, to pour a decoction of it, in oil, upon the head for head-ache.

It is generally thought that there is nothing in existence more beneficial to the abdomen and intestines than anise; for which reason it is given, parched, for dysentery and tenesmus. Some persons add opium to these ingredients, and prescribe three pills a-day, the size of a bean, with one cyathus of wine. Dieuches has employed the juice of this plant for lumbago, and prescribes the seed of it, pounded with mint, for dropsy and cœliac affections: Evenor recommends the root, also, for affections of the kidneys. Dalion, the herbalist, employed it, with parsley, as a cataplasm for women in labour, as also for pains of the uterus; and, for women in labour, he prescribes a decoction of anise and dill to be taken in drink. It is used as a liniment also in cases of phrenitis, or else applied fresh gathered and mixed with polenta; in which form it is used also for infants attacked with epilepsy or convulsions. Pythagoras, indeed, assures us that persons, so long as they hold this plant in the hand, will never be attacked with epilepsy, for which reason, as much of it as possible should be planted near the house; he says, too, that women who inhale the odour of it have a more easy delivery, it being his advice also, that,

immediately after they are delivered, it should be given them to drink, with a sprinkling of polenta.

Sosimenes employed this plant, in combination with vinegar, for all kinds of indurations, and for lassitude he prescribes a decoction of it in oil, with the addition of nitre. The same writer pledges his word to all wayfarers, that, if they take aniseed in their drink, they will be comparatively exempt from fatigue on their journey. Heraclides prescribes a pinch of aniseed with three fingers, for inflations of the stomach, to be taken with two oboli of castoreum in honied wine; and he recommends a similar preparation for inflations of the abdomen and intestines. In cases of orthopnœa, he recommends a pinch of aniseed with three fingers, and the same quantity of henbane, to be mixed in asses'-milk. It is the advice of many to those who are liable to vomit, to take, at dinner, one ace- tabulum of aniseed and ten laurel-leaves, the whole to be beaten up and drunk in water.

Anise, chewed and applied warm, or else taken with castoreum in oxymel, allays suffocations of the uterus. It also dispels vertigo after child-birth, taken with a pinch of cucumber seed in three fingers and the same quantity of linseed, in three cyathi of white wine. Tlepolemus has employed a pinch of aniseed and fennel in three fingers, mixed with vinegar and one cyathus of honey, for the cure of quartan fever. Applied topically with bitter almonds, aniseed is beneficial for maladies of the joints. There are some persons who look upon it as, by nature, an antidote to the venom of the asp. It is a diuretic, assuages thirst, and acts as an aphrodisiac. Taken in wine, it promotes a gentle perspiration, and it has the property of protecting cloth from the ravages of moths. The more recently it has been gathered, and the darker its colour, the greater are its virtues: still, however, it is injurious to the stomach, except when suffering from flatulency.

[Detailed table of contents](#)

CHAP. 74. (18.)

DILL: NINE REMEDIES.

Dill acts also as a carminative, allays gripings of the stomach, and arrests looseness of the bowels. The roots of this plant are applied topically in water, or else in wine, for defluxions of the eyes. The seed of it, if smelt at while boiling, will arrest hiccup; and, taken in water, it dispels indigestion. The ashes of it are a remedy for swellings of the uvula; but the plant itself weakens the eyesight and the generative powers.

[Detailed table of contents](#)

CHAP. 75.

SACOPENIUM, OR SAGAPENON: THIRTEEN REMEDIES.

The sacopenium which grows in Italy is totally different from that which comes from beyond sea. This last, in fact, is similar to gum ammoniac, and is known as “sagapenon.”

Sacopenium is good for pains of the sides and chest, for convulsions, coughs of long standing, expectorations, and swellings of the thoracic organs: it is a cure also for vertigo, palsy, opisthotony, affections of the spleen and loins, and for shivering fits. For suffocations of the uterus, this plant is given in vinegar to smell at; in addition to which, it is sometimes administered in drink, or employed as a friction with oil. It is a good antidote, also, for medicaments of a noxious nature.

Detailed table of contents

CHAP. 76.

THE WHITE POPPY: THREE REMEDIES. THE BLACK POPPY: EIGHT REMEDIES.
REMARKS ON SLEEP. OPIUM. REMARKS IN DISFAVOUR OF THE POTIONS
KNOWN AS "ANODYNES, FEBRIFUGES, DIGESTIVES, AND CÆLIACS." IN WHAT
WAY THE JUICES OF THESE PLANTS ARE TO BE COLLECTED.

We have already stated that there are three varieties of the cultivated poppy, and, on the same occasion, we promised to describe the wild kinds. With reference to the cultivated varieties, the calyx of the white poppy is pounded, and is taken in wine as a soporific; the seed of it is a cure, also, for elephantiasis. The black poppy acts as a soporific, by the juice which exudes from incisions made in the stalk — at the time when the plant is beginning to flower, Diagoras says; but when the blossom has gone off, according to Iollas. This is done at the third hour, in a clear, still, day, or, in other words, when the dew has thoroughly dried upon the poppy. It is recommended to make the incision just beneath the head and calyx of the plant; this being the only kind, in fact, into the head of which the incision is made. This juice, like that of any other plant, is received in wool; or else, if it is in very minute quantities, it is scraped off with the thumb nail just as it is from the lettuce, and so again on the following day, with the portion that has since dried there. If obtained from the poppy in sufficiently large quantities, this juice thickens, after which it is kneaded out into lozenges, and dried in the shade. This juice is possessed not only of certain soporific qualities, but, if taken in too large quantities, is productive of sleep unto death even: the name given to it is "opium." It was in this way, we learn, that the father of P. Licinius Cæcina, a man of Prætorian rank, put an end to his life at Babilum in Spain, an incurable malady having rendered existence quite intolerable to him. Many other persons, too, have ended their lives in a similar way. It is for this reason that opium has been so strongly exclaimed against by Diagoras and Erasistratus; for they have altogether condemned it as a deadly poison, forbidding it to be used for infusions even, as being injurious to the sight. Andreas says, in addition to this, that the only reason why it does not cause instantaneous blindness, is the fact that they adulterate it at Alexandria. In later times, however, the use of it has not been disapproved of — witness the celebrated preparation known as "diacodion." Lozenges are also made of ground poppy-seed, which are taken in milk as a soporific. The seed is employed, too, with rose-oil for head-ache; and, in combination with that oil, is injected into the ears for ear-ache. Mixed with woman's milk, this seed is used as a liniment for gout: the leaves, too, are employed in a similar manner. Taken in vinegar, the seed is prescribed as a cure for erysipelas and wounds.

For my own part, however, I do not approve of opium entering into the composition of eye-salves, and still less of the preparations from it known as febrifuges, digestives, and cœliacs: the black poppy, however, is very

generally prescribed, in wine, for cœliac affections. All the cultivated poppies are larger than the others, and the form of the head is round. In the wild poppy the head is elongated and small, but it is possessed of more active properties than the others in every respect. This head is often boiled, and the decoction of it taken to promote sleep, the face being fomented also with the water. The best poppies are grown in dry localities, and where it seldom rains.

When the heads and leaves of the poppy are boiled together, the name given to the decoction is “meconium;” it is much less powerful, however, in its effects than opium.

The principal test of the purity of opium is the smell, which, when genuine, is so penetrating as to be quite insupportable. The next best test is that obtained by lighting it at a lamp; upon which it ought to burn with a clear, brilliant flame, and to give out a strong odour when extinguished; a thing that never happens when opium has been drugged, for, in such case, it lights with the greatest difficulty, and the flame repeatedly goes out. There is another way of testing its genuineness, by water; for, if it is pure, it will float like a thin cloud upon the surface, but, if adulterated, it will unite in the form of blisters on the water. But the most surprising thing of all is the fact, that the sun’s heat in summer furnishes a test; for, if the drug is pure, it will sweat and gradually melt, till it has all the appearance of the juice when fresh gathered.

Mnesides is of opinion that the best way of preserving opium is to mix henbane seed with it; others, again, recommend that it should be kept with beans.

Detailed table of contents

CHAP. 77. (19.)

THE POPPY CALLED RHEAS: TWO REMEDIES.

The poppy which we have spoken of under the names of “rhœas” and the “erratic” poppy, forms an intermediate variety between the cultivated and the wild poppy; for it grows in the fields, it is true, but it is self-set nevertheless. Some persons eat it, calyx and all, immediately after it is gathered. This plant is an extremely powerful purgative: five heads of it, boiled in three semi-sextarii of wine, and taken in drink, have the effect of producing sleep.

[Detailed table of contents](#)

CHAP. 78.

THE WILD POPPY CALLED CERATITIS, GLAUCIUM, OR PARALIUM: SIX REMEDIES.

There is one variety of wild poppy known as “ceratitis.” It is of a black colour, a cubit in height, and has a thick root covered with bark, with a head resembling a small bud, bent and pointed at the end like a horn. The leaves of this plant are smaller and thinner than those of the other wild poppies, and the seed, which is very diminutive, is ripe at harvest. Taken with honied wine, in doses of half an acetabulum, the seed acts as a purgative. The leaves, beaten up in oil, are a cure for the white specks which form on the eyes of beasts of burden. The root, boiled down to one half, in doses of one acetabulum to two sextarii of water, is prescribed for maladies of the loins and liver, and the leaves, employed with honey, are a cure for carbuncles.

Some persons give this kind of poppy the name of “glaucion,” and others of “paralium,” for it grows, in fact, in spots exposed to exhalations from the sea, or else in soils of a nitrous nature.

Detailed table of contents

CHAP. 79.

THE WILD POPPY CALLED HERACLUM, OR APHRON: FOUR REMEDIES. DIACODION.

There is another kind of wild poppy, known as “heraclion” by some persons, and as “aphron” by others. The leaves of it, when seen from a distance, have all the appearance of sparrows; the root lies on the surface of the ground, and the seed has exactly the colour of foam. This plant is used for the purpose of bleaching linen cloths in summer. It is bruised in a mortar for epilepsy, being given in white wine, in doses of one acetabulum, and acting as an emetic.

This plant is extremely useful, also, for the composition of the medicament known as “diacodion,” and “arteriace.” This preparation is made with one hundred and twenty heads of this or any other kind of wild poppy, steeped for two days in three sextarii of rain water, after which they are boiled in it. You must then dry the heads; which done, boil them down with honey to one half, at a slow heat. More recently, there have been added to the mixture, six drachmæ of saffron, hypocisthis, frankincense, and gum acacia, with one sextarius of raisin wine of Crete. All this, however, is only so much ostentation; for the virtue of this simple and ancient preparation depends solely upon the poppy and the honey.

[Detailed table of contents](#)

CHAP. 80.

THE POPPY CALLED TITHYMALON, OR PARALION: THREE REMEDIES.

There is a third kind, again, called “tithymalon;” some persons give it the name of “mecon,” others of “paralion.” It has a white leaf, resembling that of flax, and a head the size of a bean. It is gathered when the vine is in blossom, and dried in the shade. The seed, taken in drink, purges the bowels, the dose being half an acetabulum, in honied wine. The head of every species of poppy, whether green or dry, used as a fomentation, assuages defluxions of the eyes. Opium, if taken in pure wine immediately after the sting of a scorpion, prevents any dangerous results. Some persons, however, attribute this virtue to the black poppy only, the head or leaves being beaten up for the purpose.

Detailed table of contents

CHAP. 81. (20.)

PORCILLACA OR PURSLAIN, OTHERWISE CALLED PEPLIS: TWENTY-FIVE REMEDIES.

There is a wild purslain, too, called “peplis,” not much superior in its virtues to the cultivated kind, of which such remarkable properties are mentioned. It neutralizes the effects, it is said, of poisoned arrows, and the venom of the serpents known as hæmorrhoids and prester; taken with the food and applied to the wound, it extracts the poison. The juice, too, they say, taken in raisin wine, is an antidote for henbane. When the plant itself cannot be procured, the seed of it is found to be equally efficacious. It is a corrective, also, of impurities in water; and beaten up in wine and applied topically, it is a cure for head-ache and ulcers of the head. Chewed in combination with honey, it is curative of other kinds of sores. It is similarly applied to the region of the brain in infants, and in cases of umbilical hernia; as also for defluxions of the eyes, in persons of all ages, being applied to the forehead and temples with polenta. If employed as a liniment for the eyes, milk and honey are added, and when used for proptosis of the eyes, the leaves are beaten up with bean-shells. In combination with polenta, salt, and vinegar, it is employed as a fomentation for blisters.

Chewed raw, purslain reduces ulcerations of the mouth and gum-boils, and cures tooth-ache; a decoction of it is good, too, for ulcers of the tonsils. Some persons have added a little myrrh to it, when so employed. Chewed, it strengthens such teeth as may happen to be loose, dispels crudities, imparts additional strength to the voice, and allays thirst. Used with nutgalls, linseed, and honey, in equal proportions, it assuages pains in the neck; and, combined with honey or Cimolian chalk, it is good for diseases of the mamillæ. The seed of it, taken with honey, is beneficial for asthma. Eaten in salads, this plant is very strengthening to the stomach. In burning fevers, applications of it are made with polenta; in addition to which, if chewed, it will cool and refresh the intestines. It arrests vomiting, also, and for dysentery and abscesses, it is eaten with vinegar, or else taken with cummin in drink: boiled, it is good for tenesmus. Taken either in the food or drink, it is good for epilepsy; and, taken in doses of one acetabulum in boiled wine, it promotes the menstrual discharge. Employed, also, as a liniment with salt, it is used as a remedy for fits of hot gout and erysipelas.

The juice of this plant, taken in drink, strengthens the kidneys and bladder, and expels intestinal worms. In conjunction with oil, it is applied, with polenta, to assuage the pain of wounds, and it softens indurations of the sinews. Metrodorus, who wrote an Abridgment of Botany, says that it should be given after delivery, to accelerate the lochial discharge. It is also an antaphrodisiac, and prevents the recurrence of lascivious dreams. One of the principal personages of Spain, whose son has been Prætor, is in the habit of

carrying the root of it, to my knowledge, suspended by a string from his neck, except when he is taking the bath, for an incurable affection of the uvula; a precaution by which he has been spared all inconvenience.

I have found it stated, too, in some authors, that if the head is rubbed with a liniment of this plant, there will be no de. fluxions perceptible the whole year through. It is generally thought, however, that purslain weakens the sight.

Detailed table of contents

CHAP. 82.

CORIANDER: TWENTY-ONE REMEDIES.

There is no wild coriander to be found; the best, it is generally agreed, is that of Egypt. Taken in drink and applied to the wound, it is a remedy for the sting of one kind of serpent, known as the amphisbæna: pounded, it is healing also for other wounds, as well as for epinyctis and blisters. Employed in the same state with honey or raisins, it disperses all tumours and gatherings, and, beaten up in vinegar, it removes abscesses of an inflammatory nature. Some persons recommend three grains of it to be taken for tertian fevers, just before the fit comes on, or else in larger quantities, to be bruised and applied to the forehead. There are others, again, who think that it is attended with excellent results, to put coriander under the pillow before sunrise.

While green, it is possessed of very cooling and refreshing properties. Combined with honey or raisins, it is an excellent remedy for spreading ulcers, as also for diseases of the testes, burns, carbuncles, and maladies of the ears. Applied with woman's milk, it is good for defluxions of the eyes; and for fluxes of the belly and intestines, the seed is taken with water in drink; it is also taken in drink for cholera, with rue. Coriander seed, used as a potion with pomegranate juice and oil, expels worms in the intestines.

Xenocrates states a very marvellous fact, if true; he says, that if a woman takes one grain of this seed, the menstrual discharge will be retarded one day, if two grains, two days, and so on, according to the number of grains taken. Marcus Varro is of opinion, that if coriander is lightly pounded, and sprinkled over it with cummin and vinegar, all kinds of meat may be kept in summer without spoiling.

Detailed table of contents

CHAP. 83.

ORAGE: FOURTEEN REMEDIES.

Orage, again, is found both wild and cultivated. Pythagoras has accused this plant of producing dropsy, jaundice, and paleness of the complexion, and he says that it is extremely difficult of digestion. He asserts, also, to its disparagement, that every thing that grows near it in the garden is sure to be drooping and languid. Diodes and Dionysius have added a statement, that it gives birth to numerous diseases, and that it should never be boiled without changing the water repeatedly; they say, too, that it is prejudicial to the stomach, and that it is productive of freckles and pimples on the skin.

I am at a loss to imagine why Solo of Smyrna has stated that this plant is cultivated in Italy with the greatest difficulty. Hippocrates prescribes it with beet, as a pessary for affections of the uterus; and Lycus of Neapolis recommends it to be taken in drink, in cases of poisoning by cantharides. He is of opinion, also, that either raw or boiled, it may be advantageously employed as a liniment for inflammatory swellings, incipient boils, and all kinds of indurations; and that, mixed with oxymel and nitre, it is good for erysipelas and gout. This plant, it is said, will bring away mal-formed nails, without producing sores. There are some persons who give orage-seed with honey for jaundice, and rub the throat and tonsils with it, nitre being added as well. They employ it, also, to purge the bowels, and use the seed, boiled, as an emetic, either taken by itself, or in conjunction with mallows or lentils.

Wild orage is used for dyeing the hair, as well as the other purposes above enumerated.

Detailed table of contents

CHAP. 84. (21.)

THE MALLOW CALLED MALOPE: THIRTEEN REME- DIES. THE MALLOW CALLED MALACHE: ONE REMEDY. THE MALLOW CALLED ALTHÆA, OR PLISTOLOCHIA: FIFTY-NINE REME- DIES.

Both kinds of mallows, on the other hand, the cultivated and the wild, are held in very general esteem. These kinds are subdivided, each of them, into two varieties, according to the size of the leaf. The cultivated mallow with large leaves is known to the Greeks by the name of “malope,” the other being called “malache,” — from the circumstance, it is generally thought, that it relaxes the bowels. The wild mallow, again, with large leaves and white roots, is called “althæa,” and by some persons, on account of its salutary properties, “plistolochia.” Every soil in which mallows are sown, is rendered all the richer thereby. This plant is possessed of remarkable virtues, as a cure for all kinds of stings, those of scorpions, wasps, and similar insects, as well as the bite of the shrew-mouse, more particularly; nay, what is even more than this, if a person has been rubbed with oil in which any one of the mallows has been beaten up, or even if he carries them on his person, he will never be stung. A leaf of mallow put upon a scorpion, will strike it with torpor.

The mallow is an antidote, also, against the poisonous effects of white lead; and applied raw with saltpetre, it extracts all kinds of pointed bodies from the flesh. A decoction of it with the root, taken in drink, neutralizes the poison of the sea-hare, provided, as some say, it is brought off the stomach by vomiting.

Other marvels are also related in connection with the mallow, but the most surprising thing of all is, that if a person takes half a cyathus of the juice of any one of them daily, he will be exempt from all diseases. Left to putrefy in wine, mallows are remedial for running sores of the head, and, mixed with honey, for lichens and ulcerations of the mouth; a decoction of the root, too, is a remedy for dandriff of the head and looseness of the teeth. With the root of the mallow which has a single stem, it is a good plan to prick the parts about a tooth when it aches, until the pain has ceased. With the addition of human saliva, the mallow cleanses scrofulous sores, imposthumes of the parotid glands, and inflammatory tumours, without producing a wound. The seed of it, taken in red wine, disperses phlegm and relieves nausea; and the root, attached to the person with black wool, is a remedy for affections of the mamillæ. Boiled in milk, and taken as a pottage, it cures a cough within five days.

Sextius Niger says that mallows are prejudicial to the stomach, and Olympias, the Theban authoress, asserts that, employed with goose-grease, they are productive of abortion. Some persons are of opinion, that a good handful of the leaves, taken in oil and wine, promotes the menstrual discharge. At all events, it is a well-known fact, that if the leaves are strewed beneath a woman in labour, the delivery will be accelerated; but they must be

taken away immediately after the birth, or prolapsus of the uterus will be the consequence. Mallow-juice, also, is given to women in labour, a decoction of it being taken fasting in wine, in doses of one hemina.

Mallow seed is attached to the arms of patients suffering from spermatorrhœa; and, so naturally adapted is this plant for the promotion of lustfulness, that the seed of the kind with a single stem, sprinkled upon the genitals, will increase the sexual desire in males to an infinite degree, according to Xenocrates; who says, too, that if three roots are attached to the person, in the vicinity of those parts, they will be productive of a similar result. The same writer informs us also, that injections of mallows are good for tenesmus and dysentery, and for maladies of the rectum even, if used as a fomentation only. The juice is given warm to patients afflicted with melancholy, in doses of three cyathi, and to insane persons in doses of four. One hemina of the decoction is prescribed, also, for epilepsy. A warm decoction of the juice is employed, too, as a fomentation for calculus, flatulency, gripings of the stomach, and opisthotony. The leaves are boiled, and applied with oil, as a poultice for erysipelas and burns, and raw, with bread, to arrest inflammation in wounds. A decoction of mallows is beneficial for affections of the sinews and bladder, and for gnawing pains of the intestines; taken, too, as an aliment, or an injection, they are relaxing to the uterus, and the decoction, taken with oil, facilitates the passage of the urine.

The root of the althæa is even more efficacious for all the purposes above enumerated, and for convulsions and ruptures more particularly. Boiled in water, it arrests looseness of the bowels; and taken in white wine, it is a cure for scrofulous sores, imposthumes of the parotid glands, and inflammations of the mamillæ. A decoction of the leaves in wine, applied as a liniment, disperses inflammatory tumours; and the leaves, first dried, and then boiled in milk, are a speedy cure for a cough, however inveterate. Hippocrates prescribes a decoction of the root to be drunk by persons wounded or thirsty from loss of blood, and the plant itself as an application to wounds, with honey and resin. He also recommends it to be employed in a similar manner for contusions, sprains, and tumours of the muscles, sinews, and joints, and prescribes it to be taken in wine for asthma and dysentery. It is a singular thing, that water in which this root has been put, thickens when exposed in the open air, and congeals like ice. The more recently, however, it has been taken up, the greater are the virtues of the root.

CHAP. 85.

WILD LAPATHUM OR OXALIS, OTHERWISE CALLED LAPATHUM
CANTHERINUM, OR RUMEX: ONE REMEDY. HYDROLAPATHUM: TWO
REMEDIES. HIPPOLAPATHUM: SIX REMEDIES. OXYLAPATHUM: FOUR
REMEDIES.

Lapathum, too, has pretty nearly the same properties. There is a wild variety, known to some as “oxalis,” very similar in taste to the cultivated kind, with pointed leaves, a colour like that of white beet, and an extremely diminutive root: our people call it “rumex,” while others, again, give it the name of “lapathum cantherinum.” Mixed with axle-grease, this plant is very efficacious for scrofulous sores. There is another kind, again, hardly forming a distinct variety, known as “oxylapathon,” which resembles the cultivated kind even more than the last, though the leaves are more pointed and redder: it grows only in marshy spots. Some authors are found who speak of a “hydrolapathon,” which grows in the water, they say. There is also another variety, known as “hippolapathon,” larger than the cultivated kind, whiter, and more compact.

The wild varieties of the lapathum are a cure for the stings of scorpions, and protect those who carry the plant on their person from being stung. A decoction of the root in vinegar, employed as a gargle, is beneficial to the teeth, and if drunk, is a cure for jaundice. The seed is curative of the most obstinate maladies of the stomach. The root of hippolapathum, in particular, has the property of bringing off malformed nails; and the seed, taken in wine, in doses of two drachmæ, is a cure for dysentery. The seed of oxylapathum, washed in rain-water, with the addition of a piece of gum acacia, about the size of a lentil, is good for patients troubled with spitting of blood. Most excellent lozenges are made of the leaves and root of this plant, with the addition of nitre and a little incense. When wanted for use, they are first steeped in vinegar.

Detailed table of contents

CHAP. 86.

CULTIVATED LAPATHUM: TWENTY-ONE REMEDIES. BULAPATHUM: ONE
REMEDY.

As to garden lapathum, it is good in liniments on the forehead for defluxions of the eyes. The root of it cures lichens and leprous sores, and a decoction of it in wine is remedial for scrofulous swellings, imposthumes of the parotid glands, and calculus of the bladder. Taken in wine it is a cure for affections of the spleen, and employed as a fomentation, it is equally good for coeliac affections, dysentery, and tenesmus. For all these purposes, the juice of lapathum is found to be even still more efficacious. It acts as a carminative and diuretic, and dispels films on the eyes: put into the bath, or else rubbed upon the body, without oil, before taking the bath, it effectually removes all itching sensations. The root of it, chewed, strengthens the teeth, and a decoction of it in wine arrests looseness of the stomach: the leaves, on the other hand, relax it.

Not to omit any particulars, Solo has added to the above varieties a bulapathon, which differs only from the others in the length of the root. This root, taken in wine, is very beneficial for dysentery.

CHAP. 87. (22.)

MUSTARD, THE THREE KINDS OF IT: FORTY-FOUR REMEDIES.

Mustard, of which we have mentioned three different kinds, when speaking of the garden herbs, is ranked by Pythagoras among the very first of those plants the pungency of which mounts upwards; for there is none to be found more penetrating to the brain and nostrils.

Pounded with vinegar, mustard is employed as a liniment for the stings of serpents and scorpions, and it effectually neutralizes the poisonous properties of fungi. To cure an immoderate secretion of phlegm it is kept in the mouth till it melts, or else it is mixed with hydromel, and employed as a gargle. Mustard is chewed for tooth-ache, and is taken as a gargle with oxymel for affections of the uvula; it is very beneficial, also, for all maladies of the stomach. Taken with the food, it facilitates expectoration from the lungs: it is given, too, for asthma and epileptic fits, in combination with cucumber seed. It has the effect of quickening the senses, and effectually clears the head by sneezing, relaxes the stomach, and promotes the menstrual discharge and the urinary secretions: beaten up with figs and cummin, in the proportion of one-third of each ingredient, it is used as an external application for dropsy.

Mixed with vinegar, mustard resuscitates by its powerful odour persons who have swooned in fits of epilepsy or lethargy, as well as females suffering from hysterical suffocations. For the cure of lethargy tordylon is added—that being the name given to the seed of hartwort — and if the lethargic sleep should happen to be very profound, an application of it, with figs and vinegar, is made to the legs, or to the head even. Used as an external application, mustard is a cure for inveterate pains of the chest, loins, hips, shoulders, and, in general, for all deep-seated pains in any part of the body, raising blisters by its caustic properties. In cases of extreme indurations of the skin, the mustard is applied to the part without figs; and a cloth is employed doubled, where it is apprehended that it may burn too powerfully. It is used also, combined with red-earth, for alopecy, itch-scabs, leprosy, phthiriasis, tetanus, and opisthotony. They employ it also as a liniment with honey for stytes on the eyelids and films on the eyes.

The juices of mustard are extracted in three different ways, in earthen vessels in which it is left to dry gradually in the sun. From the thin stem of the plant there exudes also a milky juice, which when thus hardened is remedial for tooth-ache. The seed and root, after they have been left to steep in must, are beaten up together in a mortar; and a good handful of the mixture is taken to strengthen the throat, stomach, eyes, head, and all the senses. This mixture is extremely good, too, for fits of lassitude in females, being one of the most wholesome medicines in existence. Taken in vinegar, mustard disperses calculi in the bladder; and, in combination with honey and goose-grease, or

else Cyprian wax, it is employed as a liniment for livid spots and bruises. From the seed, first steeped in olive-oil, and then subjected to pressure, an oil is extracted, which is employed for rigidity of the sinews, and chills and numbness in the loins and hips.

Detailed table of contents

CHAP. 88.

ADACA: FORTY-EIGHT REMEDIES.

It is said that adarca, of which we have already made mention when speaking of the forest-trees, has a similar nature to that of mustard, and is productive of the same effects: it grows upon the outer coat of reeds, below the head.

Detailed table of contents

CHAP. 89.

MARRUBIUM OR PRASION, OTHERWISE LINOSTROPHON, PHILOPAIS, OR
PHILOCHARES: TWENTY-NINE REMEDIES.

Most medical writers have spoken in high terms of marru- bium, or horehound, as a plant of the very greatest utility. Among the Greeks, it is called “prasion” by some, by others “linostrophon,” and by others, again, “philopais” or “philochares:” it is a plant too well known to require any description. The leaves and seed beaten up, together, are good for the stings of serpents, pains of the chest and side, and inveterate coughs. The branches, too, boiled in water with panic, so as to modify its acridity, are remarkably useful for persons troubled with spitting of blood. Horehound is applied also, with grease, to scrofulous swellings. Some persons recommend for a cough, a pinch of the fresh seed with two fingers, boiled with a handful of spelt and a little oil and salt, the mixture to be taken fasting. Others, again, regard as quite incomparable for a similar purpose an extract of the juices of horehound and fennel. Taking three sextarii of the extract, they boil it down to two, and then add one sextarius of honey; after which they again boil it down to two, and administer one spoonful of the preparation daily, in one cyathus of water.

Beaten up with honey, horehound is particularly beneficial for affections of the male organs; employed with vinegar, it cleanses lichens, and is very salutary for ruptures, convulsions, spasms, and contractions of the sinews. Taken in drink with salt and vinegar, it relaxes the bowels, promotes the menstrual discharge, and accelerates the after-birth. Dried, powdered, and taken with honey, it is extremely efficacious for a dry cough, as also for gangrenes and hang-nails. The juice, too, taken with honey, is good for the ears and nostrils: it is a remedy also for jaundice, and diminishes the bilious secretions. Among the few antidotes for poisons, it is one of the very best known.

The plant itself, taken with iris and honey, purges the stomach and promotes expectorations: it acts, also, as a strong diuretic, though, at the same time, care must be taken not to use it when the bladder is ulcerated and the kidneys are affected. It is said, too, that the juice of horehound improves the eyesight. Castor speaks of two varieties of it, the black horehound and the white, which last he considers to be the best. He puts the juice of it into an empty eggshell, and then mixes the egg with it, together with honey, in equal proportions: this preparation used warm, he says, will bring abscesses to a head, and cleanse and heal them. Beaten up, too, with stale axle-grease and applied topically, he says, hore- hound is a cure for the bite of a dog.

CHAP. 90.

WILD THYME: EIGHTEEN REMEDIES.

Wild thyme, it is said, borrows its name, “serpyllum,” from the fact that it is a creeping plant, a property peculiar to the wild kind, that which grows in rocky places more particularly. The cultivated thyme is not a creeping plant, but grows up- wards, as much a palm in height. That which springs up spontaneously, grows the most luxuriantly, its leaves and branches being whiter than those of the other kinds. Thyme is efficacious as a remedy for the stings of serpents, the cun- chris more particularly; also for the sting of the scolopendra, both sea and land, the leaves and branches being boiled for the purpose in wine. Burnt, it puts to flight all venomous crea- tures by its smell, and it is particularly beneficial as an antidote to the venom of marine animals.

A decoction of it in vinegar is applied for head-ache, with rose oil, to the temples and forehead, as also for phrenitis and lethargy: it is given, too, in doses of four drachmæ, for gripings of the stomach, strangury, quinsy, and fits of vomiting. It is taken in water, also, for liver complaints. The leaves are given in doses of four oboli, in vinegar, for diseases of the spleen. Beaten up in two cyathi of oxymel, it is used for spitting of blood.

Detailed table of contents

CHAP. 91.

SISYMBRIUM OR THYMBRÆUM: TWENTY-THREE REMEDIES.

Wild sisymbrium, by some persons called “thymbræum.” does not grow beyond a foot in height. The kind which grows in watery places, is similar to nasturtium, and they are both of them efficacious for the stings of certain insects, such as hornets and the like. That which grows in dry localities is odoriferous, and is employed for wreaths: the leaf of it is narrower than in the other kind. They both of them alleviate head-ache, and defluxions of the eyes, Philinus says. Some persons, however, employ bread in addition; while others, again, use a decoction of the plant by itself in wine. It is a cure, also, for epinyctis, and removes spots on the face in females, by the end of four days; for which purpose, it is applied at night and taken off in the day-time. It arrests vomiting, hiccup, gripings, and fluxes of the stomach, whether taken with the food, or the juice extracted and given in drink.

This plant, however, should never be eaten by pregnant women, except in cases where the fœtus is dead, for the very application of it is sufficient to produce abortion. Taken with wine, it is diuretic, and the wild variety expels calculi even. For persons necessitated to sit up awake, an infusion of it in vinegar is applied as a liniment to the head.

[Detailed table of contents](#)

CHAP. 92.

LINSEED: THIRTY REMEDIES.

Linseed is not only used in combination with other substances, but, employed by itself, it disperses spots on the face in women: its juice, too, is very beneficial to the sight. Combined with incense and water, or else with myrrh and wine, it is a cure for defluxions of the eyes, and employed with honey, grease, or wax, for imposthumes of the parotid glands. Prepared like polenta, it is good for fluxes of the stomach; and a decoction of it in water and oil, applied topically with anise, is prescribed for quinsy. It is sometimes used parched, also, to arrest looseness of the bowels, and applications of it are used, with vinegar, for cœliac affections and dysentery. It is eaten with raisins, also, for pains in the liver, and excellent electuaries are made of it for the treatment of phthisis.

Linseed-meal, with the addition of nitre, salt, or ashes, softens rigidities of the muscles, sinews, joints, and vertebræ, as well as of the membranous tissues of the brain. Employed with figs, linseed-meal ripens abscesses and brings them to a head: mixed with the root of wild cucumber, it extracts all foreign bodies from the flesh, as well as splinters of broken bones. A decoction of linseed-meal in wine prevents ulcers from spreading, and mixed with honey, it is remedial for pituitous eruptions. Used with nasturtium, in equal quantities, it rectifies malformed nails; mixed with resin and myrrh, it cures affections of the testes and hernia, and with water, gangrenous sores. A decoction of linseed-meal with fenugreek, in the proportion of one sextarius of each, in hydromel, is recommended for pains in the stomach; and employed as an injection, with oil or honey, it is beneficial for dangerous affections of the chest and intestines.

[Detailed table of contents](#)

CHAP. 93.

BLITE: SIX REMEDIES.

Blite seems to be a plant of an inert nature, without flavour or any pungency whatever; hence it is that, in Menander, we find husbands giving this name to their wives, by way of reproach. It is prejudicial to the stomach, and disturbs the bowels to such a degree, as to cause cholera in some. It is stated, however, that, taken in wine, it is good for the stings of scorpions; and that it is sometimes used as a liniment for corns on the feet, and, with oil, for affections of the spleen and pains in the temples. Hippocrates is of opinion, that if taken with the food, it will arrest the menstrual discharge.

[Detailed table of contents](#)

CHAP. 94. (23.)

MEUM, AND MEUM ATHAMANTICUM: SEVEN REMEDIES.

Meum is never cultivated in Italy except by medical men, and by very few of those. There are two varieties of it, the finer kind being known as “athamanticum,” because, according to some, it was first discovered by Athamas; or else because, as others think, that of the best quality is found upon Mount Athamas. The leaf of it is similar to that of dill, and the stem is sometimes as much as two cubits in length: the roots, which run obliquely, are numerous and mostly black, though sometimes white: it is not of so red a hue as the other kind.

The root of this plant, pounded or boiled, and taken in water, is diuretic, and is marvellously efficacious for dispelling flatulency of the stomach. It is good, too, for gripings of the bowels and affections of the bladder: applied with honey to the region of the uterus, it acts as a diuretic; and used as a liniment with parsley, upon the lower regions of the abdomen in infants, it has a similar effect.

[Detailed table of contents](#)

CHAP. 95.

FENNEL: TWENTY-TWO REMEDIES.

Fennel has been rendered famous by the serpent, which tastes it, as already stated, when it casts its old skin, and sharpens its sight with the juice of this plant: a fact which has led to the conclusion that this juice must be beneficial, also, in a high degree to the human sight. Fennel-juice is gathered when the stem is swelling with the bud; after which it is dried in the sun and applied as an ointment with honey. This plant is to be found in all parts of the world. The most esteemed preparation from it, is that made in Iberia, from the tear-like drops which exude from the stalk and the seed fresh-gathered. The juice is extracted, also, from incisions made in the root at the first germination of the plant.

Detailed table of contents

CHAP. 96.

HIPPOMARATHRON, OR MYRSINEUM: FIVE REMEDIES.

There is, also, a wild variety of fennel, known by some persons as “hippomarathron,” and by others as “myrsineum;” it has a larger leaf and a more acrid taste than the other kind. It is taller, also, about the thickness of a walking-stick, and has a white root: it grows in warm, but stony localities. Diocles speaks, too, of another variety of hippomarathron, with a long narrow leaf, and a seed like that of coriander.

The seed of the cultivated fennel is medicinally employed in wine, for the stings of scorpions and serpents, and the juice of it, injected into the ears, has the effect of destroying small worms that breed there. Fennel is employed as an ingredient in nearly all our seasonings, vinegar sauces more particularly: it is placed also beneath the undercrust of bread. The seed, in fevers even, acts as an astringent upon a relaxed stomach, and beaten up with water, it allays nausea: it is highly esteemed, also, for affections of the lungs and liver. Taken in moderate quantities, it arrests looseness of the bowels, and acts as a diuretic; a decoction of it is good for gripings of the stomach, and taken in drink, it restores the milk. The root, taken in a ptisan, purges the kidneys — an effect which is equally produced by a decoction of the juice or of the seed; the root is good too, boiled in wine, for dropsy and convulsions. The leaves are applied to burning tumours, with vinegar, expel calculi of the bladder, and act as an aphrodisiac.

In whatever way it is taken in drink, fennel has the pro- perty of promoting the secretion of the seminal fluids; and it is extremely beneficial to the generative organs, whether a de- coction of the root in wine is employed as a fomentation, or whether it is used beaten up in oil. Many persons apply fennel with wax to tumours and bruises, and employ the root, with the juice of the plant, or else with honey, for the bites of dogs, and with wine for the stings of multipedes.

Hippomarathron is more efficacious, in every respect, than cultivated fennel; it expels calculi more particularly, and, taken with weak wine, is good for the bladder and irregularities of the menstrual discharge.

In this plant, the seed is more efficacious than the root; the dose of either of them being a pinch with two fingers, beaten up, and mixed with the usual drink. Petrichus, who wrote a work “On Serpents,” and Micton, who wrote a treatise “On Botany,” are of opinion that there is nothing in existence of greater efficacy against serpents than hippomarathron: indeed, Nicander has ranked it by no means among the lowest of antidotes.

CHAP. 97.

HEMP: NINE REMEDIES.

Hemp originally grew in the forests, where it is found with a blacker and rougher leaf than in the other kinds. Hempseed, it is said, renders men impotent: the juice of this seed will extract worms from the ears, or any insect which may have entered them, though at the cost of producing head-ache. The virtues of hemp, it is said, are so great, that an infusion of it in water will cause it to coagulate: hence it is, that if taken in water, it will arrest looseness in beasts of burden. A decoction of the root in water, relaxes contractions of the joints, and cures gout and similar maladies. It is applied raw to burns, but it must be frequently changed, so as not to let it dry.

[Detailed table of contents](#)

CHAP. 98.

FENNEL-GIANT: EIGHT REMEDIES.

Fennel-giant has a seed similar to that of dill. That which has a single stem, bifurcated at the top, is generally thought to be the female plant. The stalks of it are eaten boiled; and, pickled in brine and honey, they are recommended as particularly beneficial to the stomach; if taken, however, in too large quantities, they are apt to produce head-ache. The root of it in doses of one denarius to two cyathi of wine, is used in drink for the stings of serpents, and the root itself is applied topically for the same purpose, as also for the cure of gripings of the stomach. Taken in oil and vinegar, it is used as a check for excessive perspirations, in fevers even. The inspissated juice of fennel-giant, taken in quantities the size of a bean, acts as a purgative; and the pith of it is good for the uterus, as well as all the maladies previously mentioned. To arrest hæmorrhage, ten of the seeds are taken in drink, bruised in wine, or else with the pith of the plant. There are some persons who think that the seed should be administered for epilepsy, from the fourth to the seventh day of the moon, in doses of one spoonful.

Fennel-giant is naturally so inimical to the muræna, that the very touch of it even will kill that fish. Castor was of opinion that the juice of the root is extremely beneficial to the sight.

Detailed table of contents

CHAP. 99.

THE THISTLE OR SCOLYMOS: SIX REMEDIES.

We have already spoken, when treating of the garden plants, of the cultivation of the thistle; we may as well, therefore, not delay to mention its medicinal properties. Of wild thistles there are two varieties; one of which throws out numerous stalks immediately it leaves the ground, the other being thicker, and having but a single stem. They have, both of them, a few leaves only, and covered with prickles, the head of the plant being protected by thorny points: the last mentioned, however, puts forth in the middle of these points a purple blossom, which turns white with great rapidity, and is carried off by the wind; the Greeks give it the name of “scolymos.”

This plant, gathered before it blossoms, and beaten up and subjected to pressure, produces a juice, which, applied to the head, makes the hair grow again when it has fallen off through alopecia. The root of either kind, boiled in water, creates thirst, it is said, in those who drink it. It strengthens the stomach also, and if we are to believe what is said, has some influence upon the womb in promoting the conception of male offspring: at all events, Glaucias, who seems to have paid the most attention to the subject, has written to that effect. The thin juice, like mastich, which exudes from these plants, imparts sweetness to the breath.

[Detailed table of contents](#)

CHAP. 100. (24.)

THE COMPOSITION OF THERIACA.

But as we are now about to leave the garden plants, we will take this opportunity of describing a very famous preparation extracted from them as an antidote against the stings of all kinds of venomous animals: it is inscribed in verse upon a stone in the Temple of Æsculapius at Cos.

Take two denarii of wild thyme, and the same quantity of opopanax and meum respectively; one denarius of trefoil seed; and of aniseed, fennel-seed, ammi, and parsley, six denarii respectively, with twelve denarii of meal of fitches. Beat up these ingredients together, and pass them through a sieve; after which they must be kneaded with the best wine that can be had, and then made into lozenges of one victoriatum each: one of these is to be given to the patient, steeped in three cyathi of wine. King Antiochus the Great, it is said, employed this theriaca against all kinds of venomous animals, the asp excepted.

SUMMARY. — Remarkable facts, narratives, and observations, one thousand, five hundred, and six.

ROMAN AUTHORS QUOTED. — Cato the Censor, M. Varro, Pompeius Linnæus, C. Valgius, Hyginus, Sextius Niger who wrote in Greek, Julius Bassus who wrote in Greek, Celsus, Antonius Castor.

FOREIGN AUTHORS QUOTED. — Democritus, Theophrastus, Orpheus, Monander who wrote the “Biochresta,” Pythagoras, Nicander.

MEDICAL AUTHORS QUOTED. — Chrysippus, Diocles, Ophelion, Heraclides, Hicesius, Dionysius, Apollodorus of Citium, Apollodorus of Tarentum, Praxagoras, Plistonius, Medius, Dieuches, Cleophrantus, Philistion, Asclepiades, Crateuas, Petronius Diodotus, Iollas, Erasistratus, Diagoras, Andreas, Mnesides, Epicharmus, Damion, Dalion, Sosimenes, Tlepolemus, Metrodorus, Solo, Lycus, Olympias of Thebes, Philinus, Petrichus, Micton, Glaucias, Xenocrates.

**BOOK XXI. AN ACCOUNT OF FLOWERS. AND
THOSE USED FOR CHAPLETS MORE
PARTICULARLY.**

Detailed table of contents

CHAP. 1. (1.)

THE NATURE OF FLOWERS AND GARLANDS.

Cato has recommended that flowers for making chaplets should also be cultivated in the garden; varieties remarkable for a delicacy which it is quite impossible to express, inas- much as no individual can find such facilities for describing them as Nature does for bestowing on them their numerous tints — Nature, who here in especial shows herself in a sportive mood, and takes a delight in the prolific display of her varied productions. The other plants she has produced for our use and our nutriment, and to them accordingly she has granted years and even ages of duration: but as for the flowers and their perfumes, she has given them birth for but a day — a mighty lesson to man, we see, to teach him that that which in its career is the most beauteous and the most attractive to the eye, is the very first to fade and die.

Even the limner's art itself possesses no resources for reproducing the colours of the flowers in all their varied tints and combinations, whether we view them in groups alternately blending their hues, or whether arranged in festoons, each variety by itself, now assuming a circular form, now running obliquely, and now disposed in a spiral pattern: or whether, as we see sometimes, one wreath is interwoven within another.

Detailed table of contents

CHAP. 2. (2.)

GARLANDS AND CHAPLETS.

The ancients used chaplets of diminutive size, called “struppi;” from which comes our name for a chaplet, “stro- phium.” Indeed, it was only by very slow degrees that this last word became generalized, as the chaplets that were used at sacrifices, or were granted as the reward of military valour, asserted their exclusive right to the name of “corona.” As for garlands, when they came to be made of flowers, they received the name of “serta,” from the verb “sero,” or else from our word “series.” The use of flowers for garlands is not so very ancient, among the Greeks even.

[Detailed table of contents](#)

CHAP. 3.

WHO INVENTED THE ART OF MAKING GARLANDS: WHEN THEY FIRST RECEIVED THE NAME OF “COROLLÆ,” AND FOR WHAT REASON.

For in early times it was the usage to crown the victors in the sacred contests with branches of trees: and it was only at a later period, that they began to vary their tints by the combination of flowers, to heighten the effect in turn by their colour and their smell — an invention due to the ingenuity of the painter Pausias, at Sicyon, and the garland-maker Glyccra, a female to whom he was greatly attached, and whose handiwork was imitated by him in colours. Challenging him to a trial of skill, she would repeatedly vary her designs, and thus it was in reality a contest between art and Nature; a fact which we find attested by pictures of that artist even still in existence, more particularly the one known as the “Stephane- plocos,” in which he has given a likeness of Glycera herself. This invention, therefore, is only to be traced to later than the Hundredth Olympiad.

Chaplets of flowers being now the fashion, it was not long before those came into vogue which are known to us as Egyptian chaplets; and then the winter chaplets, made for the time at which Earth refuses her flowers, of thin laminæ of horn stained various colours. By slow degrees, too, the name was introduced at Rome, these garlands being known there at first as “corollæ,” a designation given them to express the remarkable delicacy of their texture. In more recent times, again, when the chaplets presented were made of thin plates of copper, gilt or silvered, they assumed the name of “corollaria.”

Detailed table of contents

CHAP. 4. (3.)

WHO WAS THE FIRST TO GIVE CHAPLETS WITH LEAVES OF SILVER AND GOLD.
LEMNISCI: WHO WAS THE FIRST TO EMBOSS THEM.

Crassus Dives was the first who gave chaplets with artificial leaves of silver and gold, at the games celebrated by him. To embellish these chaplets, and to confer additional honour on them, lemnisci were added, in imitation of the Etruscan chaplets, which ought properly to have none but lemnisci made of gold. For a long period these lemnisci were destitute of ornament: P. Claudius Pulcher was the first who taught us to emboss them, and added leaves of tinsel to the laminæ of which the lemniscus was formed.

[Detailed table of contents](#)

CHAP. 5.

THE GREAT HONOUR IN WHICH CHAPLETS WERE HELD BY THE ANCIENTS.

Chaplets, however, were always held in a high degree of estimation, those even which were acquired at the public games. For it was the usage of the citizens to go down in person to take part in the contests of the Circus, and to send their slaves and horses thither as well. Hence it is that we find it thus written in the laws of the Twelve Tables: "If any person has gained a chaplet himself, or by his money, let the same be given to him as the reward of his prowess." There is no doubt that by the words "gained by his money," the laws meant a chaplet which had been gained by his slaves or horses. Well then, what was the honour acquired thereby? It was the right secured by the victor, for himself and for his parents, after death, to be crowned without fail, while the body was laid out in the house, and on its being carried to the tomb.

On other occasions, chaplets were not indiscriminately worn, not even those which had been won in the games.

Detailed table of contents

CHAP. 6.

THE SEVERITY OF THE ANCIENTS IN REFERENCE TO CHAPLETS.

Indeed the rules upon this point were remarkably severe. L. Fulvius, a banker, having been accused, at the time of the Second Punic War, of looking down from the balcony of his house upon the Forum, with a chaplet of roses upon his head, was imprisoned by order of the Senate, and was not liberated before the war was brought to a close. P. Munatius, having placed upon his head a chaplet of flowers taken from the statue of Marsyas, was condemned by the Triumviri to be put in chains. Upon his making appeal to the tribunes of the people, they refused to intercede in his behalf — a very different state of things to that at Athens, where the young men, in their drunken revelry, were in the habit, before midday, of making their way into the very schools of the philosophers even. Among ourselves, no such instance of a similar licentiousness is to be found, unless, indeed, in the case of the daughter of the late Emperor Augustus, who, in her nocturnal debaucheries, placed a chaplet on the statue of Marsyas, conduct deeply deplored in the letters of that god.

Detailed table of contents

CHAP. 7.

A CITIZEN DECKED WITH FLOWERS BY THE ROMAN PEOPLE.

Scipio is the only person that ever received from the Roman people the honour of being decked with flowers. This Scipio received the surname of Serapio, from his remarkable resemblance to a certain person of that name who dealt in pigs. He died in his tribuneship, greatly beloved by the people, and in every way worthy of the family of the Africani. The property he left was not sufficient to pay the expenses of his burial; upon which the people made a subscription and contracted for his funeral, flowers being scattered upon the body from every possible quarter as it was borne along.

[Detailed table of contents](#)

CHAP. 8.

PLAITED CHAPLETS. NEEDLE-WORK CHAPLETS. NARD-LEAF CHAPLETS.
SILKEN CHAPLETS.

In those days, too, chaplets were employed in honour of the gods, the Lares, public as well as domestic, the sepulchres, and the Manes. The highest place, however, in public estimation, was held by the plaited chaplet; such as we find used by the Salii in their sacred rites, and at the solemnization of their yearly banquets. In later times, the rose chaplet has been adopted, and luxury arose at last to such a pitch that a chaplet was held in no esteem at all if it did not consist entirely of leaves sown together with the needle. More recently, again, they have been imported from India, or from nations beyond the countries of India.

But it is looked upon as the most refined of all, to present chaplets made of nard leaves, or else of silk of many colours steeped in unguents. Such is the pitch to which the luxuriousness of our women has at last arrived!

Detailed table of contents

CHAP. 9.

AUTHORS WHO HAVE WRITTEN ON FLOWERS. AN ANECDOTE RELATIVE TO QUEEN CLEOPATRA AND CHAPLETS.

Among the Greeks, the physicians Mnesitheus and Callimachus have written separate treatises on the subject of chaplets, making mention of such flowers as are injurious to the head. For, in fact, the health is here concerned to some extent, as it is at the moments of carousal and gaiety in particular that penetrating odours steal insidiously upon the brain — witness an instance in the wicked cunning displayed upon one occasion by Cleopatra.

At the time when preparations were making for the battle that was eventually fought at Actium, Antonius held the queen in such extreme distrust as to be in dread of her very attentions even, and would not so much as touch his food, unless another person had tasted it first. Upon this, the queen, it is said, wishing to amuse herself with his fears, had the extremities of the flowers in a chaplet dipped in poison, and then placed it upon her head. After a time, as the hilarity increased apace, she challenged Antonius to swallow the chap-lets, mixed up with their drink. Who, under such circumstances as these, could have apprehended treachery? Accordingly, the leaves were stripped from off the chaplet, and thrown into the cup. Just as Antonius was on the very point of drinking, she arrested his arm with her hand.— “Behold, Marcus Antonius,” said she, “the woman against whom you are so careful to take these new precautions of yours in employing your tasters! And would then, if I could exist without you, either means or opportunity of effecting my purpose be wanting to me?” Saying this, she ordered a man to be brought from prison, and made him drink off the potion; he did so, and fell dead upon the spot.

Besides the two authors above-mentioned, Theophrastus, among the Greeks, has written on the subject of flowers. Some of our own writers also have given the title of “Anthologica” to their works, but no one, to my knowledge at least, has treated expressly of flowers. In fact, we ourselves have no intention here of discussing the mode of wearing chaplets, for that would be frivolous indeed; but shall proceed to state such particulars in relation to flowers as shall appear to us deserving of remark.

Detailed table of contents

CHAP. 10. (4.)

THE ROSE: TWELVE VARIETIES OF IT.

The people of our country were acquainted with but very few garland flowers among the garden plants, and those few hardly any but the violet and the rose. The plant which bears the rose is, properly speaking, more of a thorn than a shrub — indeed, we sometimes find it growing on a bramble even; the flower having, even then, a pleasant smell, though by no means penetrating. The flower in all roses is originally enclosed in a bud, with a grained surface within, which gradually swells, and assumes the form of a green pointed cone, similar to our alabaster unguent boxes in shape. Gradually acquiring a ruddy tint, this bud opens little by little, until at last it comes into full blow, developing the calyx, and embracing the yellow-pointed filaments which stand erect in the centre of it.

The employment of the rose in chaplets is, so to say, the least use that is made of it. The flower is steeped in oil, a practice which has prevailed from the times of the Trojan war, as Homer bears witness; in addition to which, it now forms an ingredient in our unguents, as mentioned on a previous occasion. It is employed also by itself for certain medicinal purposes, and is used in plasters and eye-salves for its penetrating qualities: it is used, also, to perfume the delicacies of our banquets, and is never attended with any noxious results.

The most esteemed kinds of rose among us are those of Præneste and Campania. Some persons have added to these varieties the rose of Miletus, the flower of which is an extremely brilliant red, and has never more than a dozen petals. The next to it is the rose of Trachyn, not so red as the last, and then that of Alabanda, with whitish petals, but not so highly esteemed. The least esteemed of all, however, is the thorn rose, the petals of which are numerous, but extremely small. The essential points of difference in the rose are the number of the petals, the comparative number of thorns on the stem, the colour, and the smell. The number of the petals, which is never less than five, goes on increasing in amount, till we find one variety with as many as a hundred, and thence known as the “centifolia:” in Italy, it is to be found in Campania, and in Greece, in the vicinity of Philippi, though this last is not the place of its natural growth. Mount Pangæus, in the same vicinity, produces a rose with numerous petals of diminutive size: the people of those parts are in the habit of transplanting it, a method which greatly tends to improve its growth. This kind, however, is not remarkable for its smell, nor yet is the rose which has a very large or very broad petal: indeed, we may state in a few words, that the best proof of the perfume of the flower is the comparative roughness of the calyx.

Cæpio, who lived in the reign of the Emperor Tiberius, asserts that the

centifolia is never employed for chaplets, except at the extreme points of union as it were, being remarkable neither for its smell nor its beauty. There is another variety of rose, too, called the "Grecian" rose by our people, and "lychnis" by the Greeks: it grows nowhere except in humid soils, and has never more than five petals: it does not exceed the violet in size, and is destitute of smell. There is another kind, again, known to us as the "Græcula," the petals of which are tightly rolled together, and which never open except when pressed in the hand, it having always the appearance, in fact, of being in bud: the petals of it are remarkably large. Another kind, again, springs from a stem like that of the mallow, the leaves being similar to those of the olive — the name given to it is "macetum." There is the rose of autumn, too, known to us as the "coroniola," which is of a middle size, between the varieties just mentioned. All these kinds, however, are destitute of smell, with the exception of the coroniola, and the one which grows on the bramble: so extended is the scope for fictitious productions!

And, indeed, the genuine rose, for the most part, is indebted for its qualities to the nature of the soil. That of Cyrenæ is the most odoriferous of all, and hence it is that the unguents of that place are so remarkably fine: at Carthage, again, in Spain, there are early roses throughout all the winter. The temperature, too, of the climate is not without its influence: for in some years we find the roses much less odoriferous than in others; in addition to which, their smell is always more powerful when grown in dry soils than in humid ones. The rose does not admit of being planted in either a rich or an argillaceous soil, nor yet on irrigated land; being contented with a thin, light earth, and more particularly attached to ground on which old building rubbish has been laid.

The rose of Campania is early, that of Miletus late, but it is the rose of Præneste that goes off the very latest of all. For the rose, the ground is generally dug to a greater depth than it is for corn, but not so deep as for the vine. It grows but very slowly from the seed, which is found in the calyx beneath the petals of the flower, covered with a sort of down; hence it is that the method of grafting is usually the one preferred, or else propagation from the eyes of the root, as in the reed. One kind is grafted, which bears a pale flower, with thorny branches of a remarkable length; it belongs to the quinquifolia variety, being one of the Greek roses. All roses are improved by being pruned and cauterized; transplanting, too, makes them grow, like the vine, all the better, and with the greatest rapidity. The slips are cut some four fingers in length or more, and are planted immediately after the setting of the Vergiliæ; then, while the west winds are prevalent, they are transplanted at intervals of a foot, the earth being frequently turned up about them.

Persons whose object it is to grow early roses, make a hole a foot in width about the root, and pour warm water into it, at the period when the buds are beginning to put forth.

CHAP. 11. (5.)

THE LILY: FOUR VARIETIES OF IT.

The lily holds the next highest rank after the rose, and has a certain affinity with it in respect of its unguent and the oil extracted from it, which is known to us as “lirinon.” Blended, too, with roses, the lily produces a remarkably fine effect; for it begins to make its appearance, in fact, just as the rose is in the very middle of its season. There is no flower that grows to a greater height than the lily, sometimes, indeed, as much as three cubits; the head of it being always drooping, as though the neck of the flower were unable to support its weight. The whiteness of the lily is quite remarkable, the petals being striated on the exterior; the flower is narrow at the base, and gradually expanding in shape like a tapering cup with the edges curving outwards, the fine pistils of the flower, and the stamens with their antheræ of a saffron colour, standing erect in the middle. Hence the perfume of the lily, as well as its colour, is two-fold, there being one for the petals and another for the stamens. The difference, however, between them is but very small, and when the flower is employed for making lily unguents and oils, the petals are never rejected.

There is a flower, not unlike the lily, produced by the plant known to us as the “convolvulus.” It grows among shrubs, is totally destitute of smell, and has not the yellow antheræ of the lily within: only vying with it in its whiteness, it would almost appear to be the rough sketch made by Nature when she was learning how to make the lily. The white lily is propagated in all the various ways which are employed for the cultivation of the rose, as also by means of a certain tearlike gum which belongs to it, similarly to hipposelinum in fact: indeed, there is no plant that is more prolific than this, a single root often giving birth to as many as fifty bulbs. There is, also, a red lily, known by the name of “crinon” to the Greeks, though there are some authors who call the flower of it “cynorrodon.” The most esteemed are those of Antiochia and Laodicea in Syria, and next to them that of Phaselis. To the fourth rank belongs the flower that grows in Italy.

Detailed table of contents

CHAP. 12.

THE NARCISSUS: THREE VARIETIES OF IT.

There is a purple lily, too, which sometimes has a double stem; it differs only from the other lilies in having a more fleshy root and a bulb of larger size, but undivided: the name given to it is “narcissus” A second variety of this lily has a white flower, with a purple corolla. There is also this difference between the ordinary lily and the narcissus, that in the latter the leaves spring from the root of the plant. The finest are those which grow on the mountains of Lycia. A third variety is similar to the others in every respect, except that the corolla of the plant is green. They are all of them late flowers: indeed, they only bloom after the setting of Arcturus, and at the time of the autumnal equinox.

Detailed table of contents

CHAP. 13.

HOW SEED IS STAINED TO PRODUCE TINTED FLOWERS.

There has been invented also a method of tinting the lily, thanks to the taste of mankind for monstrous productions. The dried stalks of the lily are tied together in the month of July, and hung up in the smoke: then, in the following March, when the small knots are beginning to disclose themselves, the stalks are left to steep in the lees of black or Greek wine, in order that they may contract its colour, and are then planted out in small trenches, some semi-sextarii of wine-lees being poured around them. By this method purple lilies are obtained, it being a very remarkable thing that we should be able to dye a plant to such a degree as to make it produce a coloured flower.

Detailed table of contents

CHAP. 14. (6.)

HOW THE SEVERAL VARIETIES OF THE VIOLET ARE RESPECTIVELY PRODUCED, GROWN, AND CULTIVATED. THE THREE DIFFERENT COLOURS OF THE VIOLET. THE FIVE VARIETIES OF THE YELLOW VIOLET.

Next after the roses and the lilies, the violet is held in the highest esteem: of this there are several varieties, the purple, the yellow, and the white, all of them reproduced from plants, like the cabbage. The purple violet, which springs up spontaneously in sunny spots, with a thin, meagre soil, has larger petals than the others, springing immediately from the root, which is of a fleshy substance. This violet has a name, too, distinct from the other wild kinds, being called “ion,” and from it the ianthine cloth takes its name.

Among the cultivated kinds, the yellow violet is held in the greatest esteem. The Tusculan violet, and that known as the “marine” violet, have petals somewhat broader than the others, but not so odoriferous; the Calatian violet, too, which has a smaller leaf, is entirely destitute of smell. This last is a present to us from the autumn, the others from the spring.

Detailed table of contents

CHAP. 15.

THE CALTHA. THE SCOPA REGIA.

Next to it comes the caltha, the flowers of which are of similar colour and size; in the number of its petals, however, it surpasses the marine violet, the petals of which are never more than five in number. The marine violet is surpassed, too, by the other in smell; that of the caltha being very powerful. The smell, too, is no less powerful in the plant known as the “scopa regia;” but there it is the leaves of the plant, and not the flowers, that are odoriferous.

Detailed table of contents

CHAP. 16.

THE BACCHAR. THE COMBRETUM. ASARUM.

The bacchar, too, by some persons known as “field nard,” is odoriferous in the root only. In former times, it was the practice to make unguents of this root, as we learn from the poet Aristophanes, a writer of the Ancient Comedy; from which circumstance some persons have erroneously given the name of “exotic” to the plant. The smell of it strongly resembles that of cinnamomum; and the plant grows in thin soils, which are free from all humidity.

The name of “combretum” is given to a plant that bears a very strong resemblance to it, the leaves of which taper to the fineness of threads; in height, however, it is taller than the bacchar. These are the only * * * * The error, however, ought to be corrected, on the part of those who have bestowed upon the bacchar the name of “field nard;” for that in reality is the surname given to another plant, known to the Greeks as “asaron,” the description and features of which we have already mentioned, when speaking of the different varieties of nard. I find, too, that the name of “asaron” has been given to this plant, from the circumstance of its never being employed in the composition of chaplets.

Detailed table of contents

CHAP. 17.

SAFFRON: IN WHAT PLACES IT GROWS BEST. WHAT FLOWERS WERE KNOWN AT THE TIME OF THE TROJAN WAR.

The wild saffron is the best; indeed, in Italy it is of no use whatever to attempt to propagate it, the produce of a whole bed of saffron being boiled down to a single scruple; it is reproduced by offsets from the bulb. The cultivated saffron is larger, finer, and better looking than the other kinds, but has much less efficacy. This plant is everywhere degenerating, and is far from prolific at Cyrenæ even, a place where the flowers are always of the very finest quality. The most esteemed saffron, however, is that of Cilicia, and there of Mount Corycus in particular; next comes the saffron of Mount Olympus, in Lycia, and then of Centuripa, in Sicily; some persons, however, have given the second rank to the Phlegreæan saffron.

There is nothing so much adulterated as saffron: the best proof of its goodness is when it snaps under pressure by the fingers, as though it were friable; for when it is moist, a state which it owes to being adulterated, it is limp, and will not snap asunder. Another way of testing it, again, is to apply it with the hand to the face, upon which, if, good, it will be found to be slightly caustic to the face and eyes. There is a peculiar kind, too, of cultivated saffron, which is in general extremely mild, being only of middling quality; the name given to it is "dialeucon." The saffron of Cyrenaica, again, is faulty in the opposite extreme; for it is darker than any other kind, and is apt to spoil very quickly. The best saffron everywhere is that which is of the most unctuous quality, and the filaments of which are the shortest; the worst being that which emits a musty smell.

Mucianus informs us that in Lycia, at the end of seven or eight years, the saffron is transplanted into a piece of ground which has been prepared for the purpose, and that in this way it is prevented from degenerating. It is never used for chaplets, being a plant with an extremely narrow leaf, as fine almost as a hair; but it combines remarkably well with wine, sweet wine in particular. Reduced to a powder, it is used to perfume the theatres.

Saffron blossoms about the setting of the Vergiliæ, for a few days only, the leaf expelling the flower. It is verdant at the time of the winter solstice, and then it is that they gather it; it is usually dried in the shade, and if in winter, all the better. The root of this plant is fleshy, and more long-lived than that of the other bulbous plants. It loves to be beaten and trodden under foot, and in fact, the worse it is treated the better it thrives: hence it is, that it grows so vigorously by the side of foot-paths and fountains. (7.) Saffron was already held in high esteem in the time of the Trojan War; at all events, Homer, we find, makes mention of these three flowers, the lotus, the saffron, and the hyacinth.

CHAP. 18.

THE NATURE OF ODOURS.

All the odoriferous substances, and consequently the plants, differ from one another in their colour, smell, and juices. It is but rarely that the taste of an odoriferous substance is not bitter; while sweet substances, on the other hand, are but rarely odoriferous. Thus it is, too, that wine is more odoriferous than must, and all the wild plants more so than the cultivated ones. Some flowers have a sweet smell at a distance, the edge of which is taken off when they come nearer; such is the case with the violet, for instance. The rose, when fresh gathered, has a more powerful smell at a distance, and dried, when brought nearer. All plants have a more penetrating odour, also, in spring and in the morning; as the hour of midday approaches, the scent becomes gradually weakened. The flowers, too, of young plants are less odoriferous than those of old ones; but it is at mid-age that the odour is most penetrating in them all.

The rose and the crocus have a more powerful smell when gathered in fine weather, and all plants are more powerfully scented in hot climates than in cold ones. In Egypt, however, the flowers are far from odoriferous, owing to the dews and exhalations with which the air is charged, in consequence of the extended surface of the river. Some plants have an agreeable, though at the same time extremely powerful smell; some, again, while green, have no smell at all, owing to the excess of moisture, the buceros for example, which is the same as fenugreek. Not all flowers which have a penetrating odour are destitute of juices, the violet, the rose, and the crocus, for example; those, on the other hand, which have a penetrating odour, but are destitute of juices, have all of them a very powerful smell, as we find the case with the two varieties of the lily. The abrotonum and the amaracus have a pungent smell. In some plants, it is the flower only that is sweet, the other parts being inodorous, the violet and the rose, for example.

Among the garden plants, the most odoriferous are the dry ones, such as rue, mint, and parsley, as also those which grow on dry soils. Some fruits become more odoriferous the older they are, the quince, for example, which has also a stronger smell when gathered than while upon the tree. Some plants, again, have no smell but when broken asunder, or when bruised, and others only when they are stripped of their bark. Certain vegetable substances, too, only give out a smell when subjected to the action of fire, such as frankincense and myrrh, for example. All flowers are more bitter to the taste when bruised than when left untouched. Some plants preserve their smell a longer time when dried, the melilote, for example; others, again, make the place itself more odoriferous where they grow, the iris for instance, which will even render the whole of a tree odoriferous, the roots of which it may happen

to have touched. The hesperis has a more powerful odour at night, a property to which it owes its name.

Among the animals, we find none that are odoriferous, unless, indeed, we are inclined to put faith in what has been said about the panther.

Detailed table of contents

CHAP. 19.

THE IRIS.

There is still another distinction, which ought not to be omitted, — the fact, that many of the odoriferous plants never enter into the composition of garlands, the iris and the saliunca, for example, although, both of them, of a most exquisite odour. In the iris, it is the root only that is held in esteem, it being extensively employed in perfumery and medicine. The iris of the finest quality is that found in Illyricum, and in that country, even, not in the maritime parts of it, but in the forests on the banks of the river Drilon and near Narona. The next best is that of Macedonia, the plant being extremely elongated, white, and thin. The iris of Africa occupies the third rank, being the largest of them all, and of an extremely bitter taste.

The iris of Illyricum comprehends two varieties — one of which is the raphanitis, so called from its resemblance to the radish, of a somewhat red colour, and superior in quality to the other, which is known as the “rhizotomus.” The best kind of iris is that which produces sneezing when handled. The stem of this plant is a cubit in length, and erect, the flower being of various colours, like the rainbow, to which circumstance it is indebted for its name. The iris, too, of Pisidia is far from being held in disesteem. Persons who intend taking up the iris, drench the ground about it some three months before with hydromel, as though a sort of atonement offered to appease the earth; with the point of a sword, too, they trace three circles round it, and the moment they gather it, they lift it up towards the heavens.

The iris is a plant of a caustic nature, and when handled, it causes blisters like burns to rise. It is a point particularly recommended, that those who gather it should be in a state of chastity. The root, not only when dried, but while still in the ground, is very quickly attacked by worms. In former times, it was Leucas and Elis that supplied us with the best oil of iris, for there it has long been cultivated; at the present day, however, the best comes from Pamphylia, though that of Cilicia and the northern climates is held in high esteem.

Detailed table of contents

CHAP. 20.

THE SALIUNCA.

The saliunca has a rather short leaf, which does not admit of its being plaited for garlands, and numerous roots, by which it is held together; being more of a herb than a flower, and so closely matted and tangled that it would almost appear to have been pressed together with the hand — in short, it is a turf of a peculiar nature. This plant grows in Pannonia and the sunny regions of Noricum and the Alps, as also the vicinity of the city of Eporedia; the smell being so remarkably sweet that the crops of it have been of late quite as profitable as the working of a mine. This plant is particularly valued for the pleasant smell it imparts to clothes among which it is kept.

[Detailed table of contents](#)

CHAP. 21.

THE POLIUM, OR TEUTHRION.

It is the same, too, with the polium, a herb employed for a similar purpose among the Greeks, and highly extolled by Musæus and Hesiod, who assert that it is useful for every purpose, and more particularly for the acquisition of fame and honour; indeed, it is a truly marvellous production, if it is the fact, as they state, that its leaves are white in the morning, purple at midday, and azure at sunset. There are two varieties of it, the field polium, which is larger, and the wild, which is more diminutive. Some persons give it the name of “teuthrion.” The leaves resemble the white hairs of a human being; they take their rise immediately from the root, and never exceed a palm in height.

Detailed table of contents

CHAP. 22. (8.)

FABRICS WHICH RIVAL THE COLOURS OF FLOWERS.

We have now said enough on the subject of the odoriferous flowers; in relation to which, luxury not only glories in having vanquished Nature in the composition of unguents, but has even gone so far as to challenge, in her fabrics, those flowers which are more particularly recommended by the beauty of their tints. I remark that the following are the three principal colours; the red, that of the kermes for instance, which, beginning in the tints of the rose, reflects, when viewed sideways and held up to the light, the shades that are found in the Tyrian purple, and the colours of the dibapha and Laconian cloths: the amethystine colour, which is borrowed from the violet, and to which, bordering as it does on the purple, we have given the name of “ianthinum” — it must, however, be remembered, that we here give a general name to a colour which is subdivided into numerous tints — and a third, properly known as the “conchyliated” colour, but which comprehends a variety of shades, such, for instance, as the tints of the heliotropium, and others of a deeper colour, the hues of the mallow, inclining to a full purple, and the colours of the late violet; this last being the most vivid, in fact, of all the conchyliated tints. The rival colours being now set side by side, Nature and luxury may enter the lists, to vie for the mastery.

I find it stated that, in the most ancient times, yellow was held in the highest esteem, but was reserved exclusively for the nuptial veils of females; for which reason it is perhaps that we do not find it included among the principal colours, those being used in common by males and females: indeed, it is the circumstance of their being used by both sexes in common that gives them their rank as principal colours.

Detailed table of contents

CHAP. 23.

THE AMARANTH.

There is no doubt that all the efforts of art are surpassed by the amaranth, which is, to speak correctly, rather a purple ear than a flower, and, at the same time, quite inodorous. It is a marvellous feature in this plant, that it takes a delight in being gathered; indeed, the more it is plucked, the better it grows. It comes into flower in the month of August, and lasts throughout the autumn. The finest of all is the amaranth of Alexandria, which is generally gathered for keeping; for it is a really marvellous fact, that when all the other flowers have gone out, the amaranth, upon being dipped in water, comes to life again: it is used also for making winter chaplets. The peculiar quality of the amaranth is sufficiently indicated by its name, it having been so called from the circumstance that it never fades.

Detailed table of contents

CHAP. 24.

THE CYANOS: THE HOLOCHRYSOS.

The name, too, of the cyanos indicates its colour, and so does that of the holochrysos. None of these flowers were in use in the time of Alexander the Great, for the authors, we find, who flourished at a period immediately after his decease, have made not the slightest mention of them; from which circumstance it is very clear that they only came into fashion at a later period. Still, however, who can entertain any doubt that they were first introduced by the Greeks, from the fact that Italy has only their Greek names by which to designate them?

Detailed table of contents

CHAP. 25.

THE PETILIUM: THE BELLIO.

But, by Hercules! it is Italy herself that has given its name to the petilium, an autumnal flower, which springs up in the vicinity of thorny brakes, and recommends itself solely by its colour, which is that of the wild rose. The petals of it are small, and five in number; and it is a remarkable circumstance in this plant, that the head of it droops at first, and it is only after it becomes erect that the petals make their appearance, forming a small corolla of various colours, enclosing a yellow seed.

The bellio, too, is a yellow flower, formed of fifty-five filaments circularly arranged, in the shape of a chaplet. These are, both of them, meadow flowers, which are mostly of no use whatever, and consequently without names: even the flowers just mentioned are known sometimes by one name, and sometimes by another.

[Detailed table of contents](#)

CHAP. 26.

THE CHRYSOCOME, OR CHRYSITIS.

The chrysocome, or chrysitis, has no Latin appellation: it is a palm in height, the flowers forming clusters of a golden colour. The root of it is black, and it has a taste both rough and sweet: it is found growing in stony and umbrageous spots.

[Detailed table of contents](#)

CHAP. 27. (9.)

SHRUBS, THE BLOSSOMS OF WHICH ARE USED FOR CHAPLETS.

Having thus passed in review nearly all the best-known colours, we must now give our attention to the chaplets which are pleasing merely on account of the variety of their materials. Of such chaplets there are two kinds, one composed of flowers, the other of leaves. The flowers so employed, I may say, are those of broom — the yellow blossom gathered from it — the rhododendron, and the jujube, also known as the tree of Cappadocia, which bears an odoriferous flower similar to that of the olive. Among the brambles, too, we find the cyclaminum growing, of which we shall have to speak more at length on a future occasion: its flower, which reflects the hues of the purple of Colossæ, is used as an ingredient in chaplets.

Detailed table of contents

CHAP. 28.

SHRUBS, THE LEAVES OF WHICH ARE USED FOR CHAPLETS.

The leaves, also, of smilax and ivy are employed in chaplets; indeed, the clusters of these plants are held in the very highest esteem for this purpose: we have already spoken of them at sufficient length when treating of the shrubs. There are also other kinds of shrubs, which can only be indicated by their Greek names, little attention having been paid by the framers of our language to this branch of nomenclature. Most of them grow in foreign countries, it is true; but still, it is our duty to make some mention of them, as it is of Nature in general that we are speaking, and not of Italy in particular.

Detailed table of contents

CHAP. 29.

THE MELOTHRON, SPIRÆA, AND ORIGANUM. THE CNEORUM OR CASSIA; TWO VARIETIES OF IT. THE MELISSOPHYLLUM OR MELITTÆNA. THE MELILOTE, OTHERWISE KNOWN AS CAMPANIAN GARLAND.

Thus it is, that we find employed for chaplets, the leaves of the melothron, spiræa, origanum, cneorum, by Hyginus called “cassia,” conyza or cunilago, melissophyllon or apiastrum, and melilote, known to us by the name of “Campanian garland,” the best kind of melilote in Italy being that of Campania, in Greece that of Cape Sunium, and next to that the produce of Chalcidice and Crete: but wherever this plant grows it is only to be found in rugged and wild localities. The name “sertula” or “garland,” which it bears, sufficiently proves that this plant was formerly much used in the composition of chaplets. The smell, as well as the flower, closely resembles that of saffron, though the stem itself is white; the shorter and more fleshy the leaves, the more highly it is esteemed.

Detailed table of contents

CHAP. 30.

THREE VARIETIES OF TREFOIL: THE MYOPHONUM.

The leaves of trefoil also are employed for making chaplets. There are three varieties: the first being called by the Greeks sometimes “minyantes,” and sometimes “asphaltion;” the leaves of it, which the garland-makers employ, are larger than those of the other kinds. The second variety, known as the “oxytriphylon,” has a pointed leaf; and the third has the smallest leaf of them all. Among these plants there are some which have a tough, sinewy stem, such as marathron, for instance, hippomarathron, and the myophonum. The umbels, too, of fennel-giant and the purple flowers of the ivy are employed for this purpose; as also another kind of ivy very similar to the wild rose, the colour only of which is attractive, the flower being quite inodorous. There are also two varieties used of the cneorum, the black and the white, this last being odoriferous: they are both of them provided with branches, and they blossom after the autumnal equinox.

(10.) There are the same number of varieties, also, of organum employed in making chaplets, one of which is destitute of seed, the other, which is also odoriferous, being known as the Cretan organum.

Detailed table of contents

CHAP. 31.

TWO VARIETIES OF THYME. PLANTS PRODUCED FROM BLOSSOMS AND NOT FROM SEED.

There are also as many varieties of thyme employed, the one white, the other dark: it flowers about the summer solstice, when the bees cull from it. From this plant a sort of augury is derived, as to how the honey is likely to turn out: for the bee-keepers have reason to look for a large crop when the thyme blossoms in considerable abundance. Thyme receives great injury from showers of rain, and is very apt to shed its blossom. The seed of thyme is so minute as to be imperceptible, and yet that of *origanum*, which is also extremely minute, does not escape the sight. But what matters it that Nature has thus concealed it from our view? For we have reason to conclude that it exists in the flower itself; which, when sown in the ground, gives birth to the plant — what is there, in fact, that the industry of man has left untried?

The honey of Attica is generally looked upon as the best in all the world; for which reason it is that the thyme of that country has been transplanted, being reproduced, as already stated, with the greatest difficulty, from the blossom. But there is also another peculiarity in the nature of the thyme of Attica, which has greatly tended to frustrate these attempts — it will never live except in the vicinity of breezes from the sea. In former times, it was the general belief that this is the case with all kinds of thyme, and that this is the reason why it does not grow in Arcadia: at a period when it was universally supposed, too, that the olive never grows beyond three hundred stadia from the sea. But, at the present day, we know for certain that in the province of Gallia Narbonensis the Stony Plains are quite overgrown with thyme; this being, in fact, the only source of revenue to those parts, thousands of sheep being brought thither from distant countries to browse upon the plant.

Detailed table of contents

CHAP. 32.

CONYZA.

There are two varieties of conyza, also, employed in making chaplets, the male plant and the female. The difference consists in the leaves, those of the female plant being thinner, more tapering, and narrower, and those of the male being of an imbricated shape, the plant having a greater number of branches. The blossom, too, of the male plant is more vivid than that of the female: in both kinds it is late in making its appearance, not till after the rising of Arcturus.

The smell of the male conyza is more powerful than that of the female plant: the latter, however, is of a more penetrating nature, for which reason it is that the female plant is held in higher esteem for the treatment of the bites of animals. The leaves of the female plant have exactly the smell of honey; and the root of the male has received the name of “libanotis” from some: we have already made mention of it on a previous occasion.

Detailed table of contents

CHAP. 33.

THE FLOWER OF JOVE. THE HEMEROCALLES. THE HELENIUM. THE PHLOX.
PLANTS IN WHICH THE BRANCHES AND ROOTS ARE ODORIFEROUS.

Of the following plants, too, it is only the leaves that are employed for chaplets — the flower of Jove, the amaracus, the hemerocalles, the abrotonum, the helenium, sisymbrium, and wild thyme, all of them ligneous plants, growing in a manner similar to the rose. The flower of Jove is pleasing only for its colours, being quite inodorous; which is the case also with the plant known by the Greek name of “phlox.” All the plants, too, which we have just mentioned are odoriferous, both in the branches and the leaves, with the sole exception of wild thyme. The helenium is said to have had its origin in the tears of Helen, and hence it is that the kind grown in the island of Helena is so highly esteemed. It is a shrub which throws out its tiny branches along the ground, some nine inches in length, with a leaf very similar to that of wild thyme.

Detailed table of contents

CHAP. 34.

THE ABROTONUM. THE ADONIUM: TWO VARIETIES OF IT. PLANTS WHICH REPRODUCE THEMSELVES. THE LEUCANTHEMUM.

The flower of the abrotonum, which makes its appearance in summer, has a powerful but agreeable smell; it is of a bright golden colour. Left to range at large, it reproduces itself by layers from the tops of the branches: but when it is propagated by the hand of man, it is better to grow it from the seed than from the roots or slips, though even from the seed it is not grown without considerable trouble. The young plants are transplanted in summer, which is the case also with the adonium. They are both of them plants of a very chilly nature, though, at the same time, they are apt to receive injury if too much exposed to the sun: when, however, they have gained sufficient strength, they throw out branches like those of rue.

The leucanthemum has a similar smell to that of the abrotonum: it is a foliated plant, with a white flower.

Detailed table of contents

CHAP. 35. (11.)

TWO VARIETIES OF THE AMARACUS.

Diodes, the physician, and the people of Sicily have given the name of “amaracus” to the plant known in Egypt and Syria as sampsuchum. It is reproduced two ways, from seed and from cuttings, being more long-lived than the preceding plants, and possessed of a more agreeable smell. The amaracus, like the abrotonum, has a great abundance of seed, but while the abrotonum has a single root, which penetrates deep into the ground, those of the other plant adhere but lightly to the surface of the earth. Those of the other plants which love the shade, water, and manure, are generally set at the beginning of autumn, and even, in some localities, in spring.

Detailed table of contents

CHAP. 36.

THE NYCTEGRETON, CHENOMYCHE, OR NYCTALOPS.

Democritus has regarded the nyctegreton as one of the most singular of plants. According to that author, it is of a dark red colour, has leaves like those of a thorn, and creeps upon the ground. He says that it grows in Gedrosia more particularly, and that it is taken up by the roots immediately after the vernal equinox, and dried in the moonlight for thirty days; after which preparation it emits light by night. He states also, that the Magi and the kings of Parthia employ this plant in their ceremonies when they make a vow to perform an undertaking; that another name given to it is “chenomyche,” from the circumstance that, at the very sight of it, geese will manifest the greatest alarm; and that by some persons, again, it is known as the “nyctalops,” from the light which it emits at a considerable distance by night.

CHAP. 37.

WHERE THE MELILOTE IS FOUND.

The melilote is found growing everywhere, though that of Attica is held in the highest esteem. In all countries, however, it is preferred when fresh gathered; that too, the colour of which is not white, but approaches as nearly as possible to the colour of saffron. In Italy, however, it is the white kind that is the most odoriferous.

CHAP. 38.

THE SUCCESSION IN WHICH FLOWERS BLOSSOM: THE SPRING FLOWERS. THE VIOLET. THE CHAPLET ANEMONE. THE CENANTHE. THE MELANION. THE HELICHRYOS. THE GLADIOLUS. THE HYACINTH.

The first of the flowers that announce the approach of spring is the white violet; indeed, in warm localities, it is seen peeping out in the winter even. Next to it comes the violet known as the ion, and the purple violet; then the flame-coloured flower, the name of which is phlox, but only the wild one. The cyclaminum blossoms twice a year, in spring and autumn, standing equally in awe as it does of summer and of winter. The narcissus and the lily, in the parts beyond sea, are a little later than the preceding plants: but in Italy, as we have already stated, they are in blossom with the rose. In Greece, too, the anemone blooms even later; it is the flower of a wild bulb, and is altogether different from the one which we shall have occasion to mention among the medicinal plants.

Next, after these, come the cœnanthe, the melanion, and, among the wild plants, the helichrysos; then, another kind of anemone, known as the “limonia,” and after that the gladiolus, accompanied by the hyacinth. Last of all, among the spring flowers, is the rose, which, with the exception indeed of the cultivated kinds, is also the first to fade. Among the others, the flowers which last the longest, are the hyacinth, the white violet, and the cœnanthe; but to make this last keep any time in flower, it is necessary to gather it repeatedly, to prevent it from running to seed. The cœnanthe grows in warm localities, and has exactly the smell of the vine when in blossom, to which circumstance it is indebted for its name.

There are two fabulous stories attached to the hyacinth; according to one of them, it bears the impress of the grief which Apollo felt for the youth whom he had so tenderly loved; and we learn from the other, that it derives its name from the blood of Ajax, the veins being so arranged in the flower as to form the Greek letters αἶ inscribed upon it.

The helichrysos has a flower resembling gold in appearance, a small leaf, and a fine, slender, but hard, stem. According to the Magi, the person who crowns himself with a chaplet composed of this flower, and takes his unguents from a box of gold, of the kind generally known as “apyron,” will be sure to secure esteem and glory among his fellowmen. Such are the flowers of spring.

CHAP. 39.

THE SUMMER FLOWERS — THE LYCHNIS: THE TIPHYON. TWO VARIETIES OF THE POTHOS. TWO VARIETIES OF THE ORSI- NUM. THE VINCAPERIVINCA OR CHAMÆDAPHNE — A PLANT WHICH IS AN EVER-GREEN.

The summer flowers come next, the lychnis the flower of Jove, and another kind of lily, as also the tiphyon and the amaracus, surnamed that of Phrygia. But the most remarkable flower of all is the pothos, of which there are two varieties, one with the flower of the hyacinth, and another with a white flower, which is generally found growing about graves, and is better able to stand bad weather. The iris, also, blossoms in summer. All these flowers pass away, however, and fade; upon which others assume their places in autumn, a third kind of lily, for instance, saffron, and two varieties of the orsinum — one of them inodorous and the other scented — making their appearance, all of them, as soon as the first autumnal showers fall.

The garland-makers employ the flowers of the thorn even for making chaplets; the tender shoots, too, of the white thorn are sometimes preserved as a choice morsel to tempt the palate.

Such is the succession of the summer flowers in the parts beyond sea: in Italy, the violet is succeeded by the rose, the lily comes on while the rose is still in flower, the cyanus succeeds the rose, and the amaranth the cyanus. As to the vin- capervinca, it is an evergreen, the branches from which run out like so many strings, the leaves surrounding the stem at each of the knots: though more generally used for the purposes of ornamental gardening, it is sometimes employed in chaplets when there is a deficiency of other flowers. From the Greeks this plant has received the name of “chamædaphne.”

Detailed table of contents

CHAP. 40.

THE DURATION OF LIFE IN THE VARIOUS KINDS OF FLOWERS.

At the very utmost, the white violet never lasts longer than three years: should it exceed that period, it is sure to degenerate. The rose-tree will last so long as five years without being pruned or cauterized, methods by which it is made to grow young again. We have already stated that the nature of the soil is of the very greatest importance; for in Egypt, we find, all these plants are perfectly inodorous, and it is only the myrtle that has any particular smell. In some countries, too, the germination of all the plants precedes that in other parts of the world by so long a period as two months even. The rose-beds should be well spaded immediately after the west winds begin to prevail, and, a second time, at the summer solstice: every care, however, should be paid, between these two periods, to keeping the ground well raked and cleaned.

Detailed table of contents

CHAP. 41. (12.)

PLANTS WHICH SHOULD BE SOWN AMONG FLOWERS FOR BEES. THE CERINTHA.

Bees and beehives, too, are a subject extremely well suited to a description of gardens and garland plants, while, at the same time, where they are successfully managed, they are a source, without any great outlay, of very considerable profit. For bees, then, the following plants should be grown — thyme, apiastrum, the rose, the various violets, the lily, the cytissus, the bean, the fitch, cunila, the poppy, conyza, cassia, the me- lilote, melissophyllum, and the cerintha. This last is a plant with a white leaf, bent inwards, the stem of it being a cubit in height, with a flower at the top presenting a concavity full of a juice like honey. Bees are remarkably fond of the flowers of these plants, as also the blossoms of mustard, a thing that is somewhat surprising, seeing that it is a well-known fact that they will not so much as touch the blossoms of the olive: for which reason, it will be as well to keep that tree at a distance from them.

There are other trees, again, which should be planted as near the hives as possible, as they attract the swarm when it first wings its flight, and so prevent the bees from wandering to any considerable distance.

Detailed table of contents

CHAP. 42.

THE MALADIES OF BEES, AND THE REMEDIES FOR THEM.

The greatest care, too, should be taken to keep the cornel at a distance from the hives: for if the bees once taste the blossoms of it, they will speedily die of flux and looseness. The best remedy in such case is to give them sorb apples beaten up with honey, or else human urine or that of oxen, or pomegranate seeds moistened with Aminean wine. It is a very good plan, too, to plant broom about the hives, the bees being extremely fond of the blossoms.

Detailed table of contents

CHAP. 43.

THE FOOD OF BEES.

In relation to the food of bees, I have ascertained a very singular fact, and one that well deserves to be mentioned. There is a village, called Hostilia, on the banks of the river Padus: the inhabitants of it, when food fails the bees in their vicinity, place the hives in boats and convey them some five miles up the river in the night. In the morning the bees go forth to feed, and then return to the boats; their locality being changed from day to day, until at last, as the boats sink deeper and deeper in the water, it is ascertained that the hives are full, upon which they are taken home, and the honey is withdrawn.

(13.) In Spain, too, for the same purpose, they have the hives carried from place to place on the backs of mules.

Detailed table of contents

CHAP. 44.

POISONED HONEY, AND THE REMEDIES TO BE EMPLOYED BY THOSE WHO HAVE EATEN OF IT.

Indeed, the food of bees is of the very greatest importance, as it is owing to this that we meet with poisonous honey even. At Heraclia in Pontus, the honey is extremely pernicious in certain years, though it is the same bees that make it at other times. Authors, however, have not informed us from what flowers this honey is extracted; we shall, therefore, take this opportunity of stating what we have ascertained upon the subject.

There is a certain plant which, from the circumstance that it proves fatal to beasts of burden, and to goats in particular, has obtained the name of “ægolcthon,” and the blossoms of which, steeped in the rains of a wet spring, contract most noxious properties, Hence it is that it is not every year that these dangerous results are experienced. The following are the signs of the honey being poisonous: it never thickens, the colour is redder than usual, and it emits a peculiar smell which immediately produces sneezing; while, at the same time, it is more weighty than a similar quantity of good honey. Persons, when they have eaten of it, throw themselves on the ground to cool the body, which is bathed with a profuse perspiration. There are numerous remedies, of which we shall have occasion to speak in a more appropriate place; but as it will be as well to mention some of them on the present occasion, by way of being provided for such insidious accidents, I will here state that old honied wine is good, mixed with the finest honey and rue; salt meats, also, taken repeatedly in small quantities, and as often brought up again.

It is a well-known fact that dogs, after tasting the excretions of persons suffering from these attacks, have been attacked with similar symptoms, and have experienced the same kind of pains.

Still, however, it is equally well ascertained, that honied wine prepared from this honey, when old, is altogether innoxious; and that there is nothing better than this honey, mixed with costus, for softening the skin of females, or, combined with aloe, for the treatment of bruises.

Detailed table of contents

CHAP. 45.

MADDENING HONEY.

In the country of the Sanni, in the same part of Pontus, there is another kind of honey, which, from the madness it produces, has received the name of “mænomenon.” This evil effect is generally attributed to the flowers of the rhododendron, with which the woods there abound; and that people, though it pays a tribute to the Romans in wax, derives no profit whatever from its honey, in consequence of these dangerous properties. In Persis, too, and in Gætulia, a district of Mauritania Cæsariensis, bordering on the country of the Massæsyli, there are poisonous honeycombs found; and some, too, only partly so, one of the most insidious things that possibly could happen, were it not that the livid colour of the honey gives timely notice of its noxious qualities. What can we suppose to have possibly been the intention of Nature in thus laying these traps in our way, giving us honey that is poisonous in some years and good in others, poisonous in some parts of the combs and not in others, and that, too, the produce in all cases of the self-same bees? It was not enough, forsooth, to have produced a substance in which poison might be administered without the slightest difficulty, but must she herself administer it as well in the honey, to fall in the way of so many animated beings? What, in fact, can have been her motive, except to render mankind a little more cautious and somewhat less greedy?

And has she not provided the very bees, too, with pointed weapons, and those weapons poisoned to boot? So it is, and I shall, therefore, without delay, set forth the remedies to counteract the effects of their stings. It will be found a very excellent plan to foment the part stung with the juice of mallows or of ivy leaves, or else for the person who has been stung to take these juices in drink. It is a very astonishing thing, however, that the insects which thus carry these poisons in their mouths and secrete them, should never die themselves in consequence; unless it is that Nature, that mistress of all things, has given to bees the same immunity from the effects of poison which she has granted against the attacks of serpents to the Psylli and the Marsi among men.

Detailed table of contents

CHAP. 46. (14.)

HONEY THAT FLIES WILL NOT TOUCH.

Another marvellous fact, again, connected with honey in Crete. Upon Mount Carma in that island, which is nine miles in circuit, there is not a fly to be found, and the honey that is made there no fly will touch. It is by this circumstance that honey said to have come from that district is usually tested, it being highly prized for medicinal preparations.

Detailed table of contents

CHAP. 47.

BEEHIVES, AND THE ATTENTION WHICH SHOULD BE PAID TO THEM.

The hives ought to have an aspect due east, but never looking towards the north-east or the west. The best hives are those made of bark, the next best those of fennel-giant, and the next of osier: many persons, too, have them made of mirror-stone, for the purpose of watching the bees at work within. It is the best plan to anoint the hives all over with cow-dung. The lid of the hive should be made to slide from behind, so as to admit of being shut to within, in case the hive should prove too large or their labours unproductive; for, if this is not done, the bees are apt to become discouraged and abandon their work. The slide may then be gradually withdrawn, the increase of space being imperceptible to the bees as the work progresses. In winter, too, the hives should be covered with straw, and subjected to repeated fumigations, with burnt cow- dung more particularly. As this is of kindred origin with the bees, the smoke produced by it is particularly beneficial in killing all such insects as may happen to breed there, such as spiders, for instance, moths, and wood-worms; while, at the same time, it stimulates the bees themselves to increased activity. In fact, there is little difficulty in getting rid of the spiders, but to destroy the moths, which are a much greater plague, a night must be chosen in spring, just when the mallow is ripening, there being no moon, but a clear sky: flam- beaux are then lighted before the hives, upon which the moths precipitate themselves in swarms into the flame.

Detailed table of contents

CHAP. 48.

THAT BEES ARE SENSIBLE OF HUNGER.

If it is found that the bees are in want of aliment, it will be a good plan to place at the entrance of the hive raisins or dried figs beaten up, as also carded wool soaked in raisin wine, boiled must, or hydromel, and sometimes even the raw flesh of poultry. In certain summers, too, when long-continued drought has deprived them of the nutriment which they usually derive from flowers, similar food must be provided for them.

When the honey is taken, the outlets of the hive should be well rubbed with melissophyllum or broom, beaten up, or else the middle of it should be encircled with bands of white vine, to prevent the bees from taking to flight. It is recommended, too, that the honey-pots and combs should be washed with water: this water, boiled, it is said, will make an extremely wholesome vinegar.

Detailed table of contents

CHAP. 49.

THE METHOD OF PREPARING WAX. THE BEST KINDS OF WAX. PUNIC WAX.

Wax is made from the honeycombs after the honey has been extracted. For this purpose, they are first cleaned with water, and then dried three days in the shade: on the fourth day they are melted on the fire in a new earthen vessel, with sufficient water to cover them, after which the liquor is strained off in a wicker basket. The wax is then boiled again with the same water and in the same pot, and poured into vessels of cold water, the interior of which has been well rubbed with honey. The best wax is that known as Punic wax, the next best being that of a remarkably yellow colour, with the smell of honey. This last comes from Pontus, and, to my surprise, it is in no way affected by the poisonous honey which it has contained. The next in quality is the Cretan wax, which contains the largest proportion of propolis, a substance of which we have previously made mention when treating of bees. Next to these varieties comes the Corsican wax, which, being the produce of the box-tree, is generally thought to be possessed of certain medicinal properties.

The Punic wax is prepared in the following manner: yellow wax is first blanched in the open air, after which it is boiled in water from the open sea, with the addition of some nitre. The flower of the wax, or, in other words, the whitest part of it, is then skimmed off with spoons, and poured into a vessel containing a little cold water. After this, it is again boiled in sea-water by itself, which done, the vessel is left to cool. When this operation has been three times repeated, the wax is left in the open air upon a mat of rushes, to dry in the light of the sun and moon; for while the latter adds to its whiteness, the sun helps to dry it. In order, however, that it may not melt, it is the practice to cover it with a linen cloth: if, when it has been thus refined, it is boiled once more, the result is a wax of the greatest possible whiteness.

Punic wax is considered the best for all medicinal preparations. Wax is made black by the addition of ashes of papyrus, and a red colour is given to it by the admixture of alkanet; indeed, by the employment of various pigments, it is made to assume various tints, in which state it is used for making models, and for other purposes without number, among which we may mention varnishing walls and armour, to protect them from the air. We have given the other particulars relative to bees and honey, when speaking of the nature of those insects. We have now stated pretty nearly all that we have to say on the subject of the pleasure garden.

CHAP. 50. (15.)

PLANTS WHICH GROW SPONTANEOUSLY: THE USE MADE OF THEM BY VARIOUS NATIONS, THEIR NATURE, AND REMARKABLE FACTS CONNECTED WITH THEM. THE STRAW- BERRY, THE TAMNUS, AND THE BUTCHER'S BROOM. THE Batis, TWO VARIETIES OF IT. THE MEADOW PARSNIP. THE HOP.

We now come to the plants which grow spontaneously, and which are employed as an aliment by most nations, the people of Egypt in particular, where they abound in such vast quantities, that, extremely prolific as that country is in corn, it is perhaps the only one that could subsist without it: so abundant are its resources in the various kinds of food to be obtained from plants.

In Italy, however, we are acquainted with but very few of them; those few being the strawberry, the tamnus, the butcher's broom, the sea batis, and the garden batis, known by some persons as Gallic asparagus; in addition to which we may mention the meadow parsnip and the hop, which may be rather termed amusements for the botanist than articles of food.

Detailed table of contents

CHAP. 51.

THE COLOCASIA.

But the plant of this nature that is the most famous in Egypt is the colocasia, known as the “cyamos” to some. It is gathered in the river Nilus, and the stalk of it, boiled, separates into fine filaments when chewed, like those of the spider’s web. The head, protruding from among the leaves, is very remarkable; and the leaves, which are extremely large, even when compared with those of trees, are very similar to those of the plant found in our rivers, and known by the name of “personata.” So much do the people of that country take advantage of the bounteousness displayed by their river, that they are in the habit of plaiting the leaves of the colocasia with such skill as to make vessels of various shapes, which they are extremely fond of using for drinking vessels. At the present day, however, this plant is cultivated in Italy.

CHAP. 52.

THE CICHORIUM. THE ANTHALIUM OR ANTICELLIUM, OR ANTHYLLUM. THE
ÆTUM. THE ARACHIDNA. THE ARACOS. THE CANDRYALA. THE HYPOCHÆRIS.
THE CAUCALIS. THE ANTHRISCUM. THE SCANDIX. THE TRAGOPOGON. THE
PAR- THENIUM OR LEUCANTHES, AMARACUS, PERDICUM, OR MURALIS. THE
TRYCHNUM OR STRYCHNUM, HALICACABUM, CALLIAS, DOR- YCNION,
MANICON, PERITTON, NEURAS, MORIO, OR MOLY. THE CORCHORUS. THE
APHACE. THE ACYNOPOS. THE EPIPETRON. PLANTS WHICH NEVER FLOWER.
PLANTS WHICH ARE ALWAYS IN FLOWER.

In Egypt, next to the colocasia, it is the cichorium that is held in the highest esteem, a plant which we have already spoken of under the name of wild endive. It springs up after the rising of the Vergiliæ, and the various portions of it blossom in succession: the root is supple, and hence is used for making withes even. The anthalium grows at a greater distance from the river; the fruit of it is round, and about the size of a medlar, but without either kernel or rind; the leaves of the plant are similar to those of the cyperus. The people there eat the fruit of it cooked upon the fire, as also of the ætum, a plant which has a few leaves only, and those extremely diminutive, though the root is large in proportion. The arachidna, again, and the aracos have numerous branchy roots, but neither leaves nor any herbaceous parts, nor, indeed, anything that makes its appearance above ground.

The other plants that are commonly eaten in Egypt are the chondrylla, the hypochæris, the caucalis, the anthriscum the scandix, the come, by some persons known as the tragopogon, with leaves very similar to those of saffron, the par- thenium, the trychnum, and the corchorus; with the aphace and acynopos, which make their appearance at the equinox. There is a plant also, called the epipetron, which never blossoms; while the aphace, on the other hand, as its flowers die, from time to time puts forth fresh ones, and remains in blossom throughout the winter and the spring, until the following summer.

Detailed table of contents

CHAP. 53.

FOUR VARIETIES OF THE CNECOS.

The Egyptians have many other plants also, of little note; but they speak in the highest terms of the cnecos; a plant unknown to Italy, and which the Egyptians hold in esteem, not as an article of food, but for the oil it produces, and which is extracted from the seed. The principal varieties are the wild and the cultivated kinds; of the wild variety, again, there are two sorts, one of which is less prickly than the other, but with a similar stem, only more upright: hence it is that in former times females used it for distaffs, from which circumstance it has received the name of “atractylis” from some; the seed of it is white, large, and bitter. The other variety is more prickly, and has a more sinewy stem, which may be said almost to creep upon the ground; the seed is small. The cnecos belongs to the thorny plants: indeed, it will be as well to make some classification of them.

Detailed table of contents

CHAP. 54.

PLANTS OF A PRICKLY NATURE: THE ERYNGE, THE GLYCYRRIZA, THE TRIBULUS, THE ANONIS, THE PHEOS OR STÆBE, AND THE HIPPOPHAES.

For some plants, in fact, are thorny, while others, again, are destitute of prickles: the species of thorny plants are very numerous. The asparagus and the scorpio are essentially thorny plants, having no leaves at all upon them. Some plants, again, that are prickly have leaves as well, such as the thistle, for instance, the erynge, the glycyrriza, and the nettle; all these plants being provided with leaves that prick or sting.

Some plants have thorns at the base of their leaves, the tribulus and the anonis for instance; others, again, have thorns, not on the leaves but on the stem, the pheos for example, known as the stæbe to some. The hippophaës has thorns at the joints; the tribulus presents the peculiarity of bearing a fruit that is thorny.

Detailed table of contents

CHAP. 55.

FOUR VARIETIES OF THE NETTLE. THE LAMIUM AND THE SCORPIO.

But of all these plants, it is the nettle that is the best known to us, the calyces of the blossoms of which produce a purple down: it frequently exceeds two cubits even in height. There are numerous varieties of this plant; the wild nettle, known also as the female nettle, does not inflict so bad a sting as the others. Among the several varieties of the wild nettle, the one known as the dog-nettle, stings the worst, the stem of it even possessing that property; the leaves of the nettle are indented at the edge. There is one kind also, which emits a smell, known as the Herculean nettle. The seed of all the nettles is copious, and black. It is a singular fact that, though possessed of no spinous points, the down of the nettle is of a noxious nature, and that, though ever so lightly touched, it will immediately produce an itching sensation, and raise a blister on the flesh similar in appearance to a burn: the well-known remedy for it is olive oil.

The stinging property of the nettle does not belong to the plant at the earliest period of its growth, but only develops itself under the influence of the sun. The plant first begins to grow in the spring, at which period it is by no means a disagreeable food; indeed, it has become quite a religious observance to employ it as such, under the impression that it is a preventive from diseases the whole year through. The root, too, of the wild nettle, has the effect of rendering all meat more tender that is boiled with it. The kind that is innoxious and destitute of all stinging properties, is known as the “*la- mium*.” Of the scorpia we shall have occasion to speak when treating of the medicinal plants.

Detailed table of contents

CHAP. 56. (16).

THE CARDUUS, THE ACORNA, THE PHONOS, THE LEUCACANTHOS, THE CHALCEOS, THE CNECOS, THE POLYACANTHOS, THE ONOPYXOS, THE HELXINE, THE SCOLYMOS, THE CHAMÆLEON, THE TETRALIX, AND ACANTHICE MASTICHE.

The carduus has leaves and a stem covered with a prickly down; the same is the case, too, with the acorna, the leucacanthos, the chalceos, the cnecos, the polyacanthos, the onopyxos, the helxine, and the scolymos; the chamæleon, however, has no prickles upon the leaves. There is, however, this difference among these plants, that some of them have numerous stems and branches, such as the carduus, for instance; while others, again, have a single stem and no branches, the cnecos, for example. Some, again, such as the erynge, are prickly at the head only; and some blossom in the summer, the tetralix and the helxine, for instance. The scolymos blossoms late, and remains a considerable period in flower: the acorna being distinguished only for its red colour and its unctuous juice. The atractylis would be similar in every respect to the last, were it not that it is somewhat whiter, and produces a juice the colour of blood, a circumstance to which it owes the name of “phonos,” given to it by some. The smell of this plant is powerful, and the seed only ripens at a late period, and never before autumn, although the same may be said of all the prickly plants, in fact. All of them are capable, however, of being reproduced from either seed or root.

The scolymos, which belongs to the thistle genus, differs from the rest of them in the circumstance that the root of it is boiled and eaten. It is a singular fact that this genus of plants bears blossoms, buds, and fruit the whole of the summer through, without any interruption: when the leaf is dried, the prickles lose their pungency. The helxine is a plant but rarely seen, and in some countries only. It throws out leaves at the root, from the middle of which there is a protuberance in the shape of an apple, covered with leaves of its own: the head of it contains a thick juice, of a sweet flavour, the name given to which is “acanthice mastiche.”

Detailed table of contents

CHAP. 57.

THE CACTOS; THE PIERNIX, PAPPUS, AND ASCALIAS.

The cactus, too, is a plant that grows only in Sicily, having peculiar characteristics of its own: the root throws out stalks which creep along the ground, the leaves being broad and thorny. The name given to these stalks is “cactus,” and they are not disliked as an article of food, even when old. The plant, however, has one stem which grows upright, and is known by the name of “piernix;” it has the same sweet flavour as the other parts, though it will not keep. The seed of it is covered with a kind of down, known as “pappus:” when this is removed, as well as the rind of the fruit, it is tender, and like the pith of the palm: the name given to it is “ascalias.”

Detailed table of contents

CHAP. 58.

THE TRIBULUS: THE ANONIS.

The tribulus grows nowhere except in marshy places though held in abomination elsewhere, it is employed on the banks of the Nilus and Strymon as an article of food. It always bends towards the water, and has a leaf like that of the elm, with a long stalk. In other parts of the world there are two varieties of this plant; the one with leaves like those of the chicheling vetch, the other with leaves protected by prickles. This last variety blossoms also at a later period than the other, and is mostly found in the hedge-rows about farm-houses. The seed of it is black, rounder than that of the other, and enclosed in pods: that of the other variety bears a resemblance to sand.

Among the prickly plants there is also another kind, known as the “anonis:” indeed, it has thorns upon the branches, to which leaves are attached similar to those of rue, the stem being entirely covered also with leaves, in form resembling a garland. It comes up in land that has been newly ploughed, being highly prejudicial to the corn, and long-lived in the extreme.

[Detailed table of contents](#)

CHAP. 59.

PLANTS CLASSIFIED ACCORDING TO THEIR STEMS: THE CORONOPUS, THE ANCHUSA, THE ANTHEMIS, THE PHYLLANTHES, THE CREPIS, AND THE LOTUS.

Some, again, among the prickly plants have a stem which creeps along the ground, that, for instance, known as the “coronopus.” On the other hand, the anchusa, the root of which is employed for dyeing wood and wax, has an upright stem; which is the case also with some of the plants that are prickly in a less degree, the anthemis, for example, the phyllanthes, the anemone, and the aphace: the crepis, again, and the lotus, have a foliated stem.

Detailed table of contents

CHAP. 60.

PLANTS CLASSIFIED ACCORDING TO THEIR LEAVES. PLANTS WHICH NEVER LOSE THEIR LEAVES: PLANTS WHICH BLOSSOM A LITTLE AT A TIME: THE HELIOTROPIUM AND THE ADIANTUM, THE REMEDIES DERIVED FROM WHICH WILL BE MENTIONED IN THE FOLLOWING BOOK.

The leaves of plants, as well as those of trees, differ from one another in the length of the footstalk, and in the breadth or narrowness of the leaf, and the angles and indentations perceptible on its edge. Other differences are also constituted in respect of their smell and blossom. The blossom remains on longer in some of those plants which flower only a little at a time, such as the ocimum, the heliotropium, the aphace, and the onochilis, for example.

(17.) Many of these plants, the same as certain among the trees, never lose their leaves, the heliotropium, the adiantum and the polium, for instance.

Detailed table of contents

CHAP. 61.

THE VARIOUS KINDS OF EARED PLANTS: THE STAN- YOPS; THE ALOPECUROS;
THE STELEPHUROS, ORTYX, OR PLAN- TAGO; THE THRYALLIS.

The eared plants form another variety: among them we find the cynops, the alopecuros, the stelephuros, also known to some persons as the ortyx, and to others as the plantago, of which last we shall have occasion to speak more at length among the medicinal plants, and the thryallis. The alopecuros, among these, has a soft ear and a thick down, not unlike a fox's tail in fact, to which resemblance it owes its name. The plant most like it is the stelephuros, were it not that it blossoms only a little at a time. In the cichorium and similar plants, the leaves are near the ground, the buds springing from the root just after the rising of the Vergiliæ.

Detailed table of contents

CHAP. 62

THE PERDICUM. THE ORNITHOGALE.

It is not in Egypt only that the perdicium is eaten; it owes its name to the partridge, which bird is extremely fond of digging it up. The roots of it are thick and very numerous: and so, too, with the ornithogale, which has a tender white stalk, and a root half a foot in thickness, bulbous, soft, and provided with three or four other offsets attached to it. It is generally used boiled in pottage.

[Detailed table of contents](#)

CHAP. 63.

PLANTS WHICH ONLY MAKE THEIR APPEARANCE AT THE END OF A YEAR.
PLANTS WHICH BEGIN TO BLOSSOM AT THE TOP. PLANTS WHICH BEGIN TO
BLOSSOM AT THE LOWER PART.

It is a remarkable thing that the herb lotus and the ægilops never make their appearance above ground till the end of a year after the seed has been sown. The anthemis, too, offers the singular peculiarity that it begins to blossom at the top, while in all the other plants which flower gradually, it is at the lower part that the blossom first makes its appearance.

Detailed table of contents

CHAP. 64.

THE LAPPA, A PLANT WHICH PRODUCES WITHIN ITSELF. THE OPUNTIA, WHICH
THROWS OUT A ROOT FROM THE LEAF.

In the lappa, too, which clings so tenaciously, there is this remarkable peculiarity, that within it there grows a flower, which does not make its appearance, but remains concealed and there produces the seed, like those among the animals which produce within themselves. In the vicinity of Opus there grows a plant which is very pleasant eating to man, and the leaf of which, a most singular thing, gives birth to a root by means of which it reproduces itself.

Detailed table of contents

CHAP. 65.

THE IASIONE. THE CHONDRYLLA. THE PICRIS, WHICH REMAINS IN FLOWER
THE WHOLE YEAR THROUGH.

The iasione has a single leaf only, but that so folded and involved, as to have all the appearance of being several in number. The chondrylla is bitter, and the juice of the root is of an acrid taste. The aphace, too, is bitter, and so is the plant called “picris,” which also remains in flower the whole year through: it is to this bitterness that it is indebted for its name.

Detailed table of contents

CHAP. 66.

PLANTS IN WHICH THE BLOSSOM MAKES ITS APPEAR- ANCE BEFORE THE STEM. PLANTS IN WHICH THE STEM APPEARS BEFORE THE BLOSSOM. PLANTS WHICH BLOSSOM THREE TIMES IN THE YEAR.

The peculiarities also of the squill and saffron deserve remark; for while all other plants put forth their leaves first, and then a round stem, these show the stem before the leaf makes its appearance: in the saffron, however, the blossom is protruded by the stem, but in the squill it is the stem that first makes its appearance, and then the flower emerges from it. This plant blossoms three times in the year, indicating thereby, as previously stated, the three seasons for ploughing.

Detailed table of contents

CHAP. 67.

THE CYPHIOS. THE THESION.

Some authors reckon among the bulbs the root of the cypiros, or gladiolus; it is a pleasant food, and when boiled and kneaded up with bread, makes it more agreeable to the taste, and at the same time more weighty. Not unlike it in appearance is the plant known to us as the “thesion,” but it is of an acrid flavour.

Detailed table of contents

CHAP. 68.

THE ASPHODEL, OR ROYAL SPEAR. THE ANTHERICUS OR ALBUCUS.

Other plants of the bulbous kind differ in the leaf: that of the asphodel is long and narrow, that of the squill broad and supple, and the form of that of the gladiolus is bespoken by its name. The asphodel is used as an article of food, the seed of it being parched, and the bulb roasted; this last, however, should be cooked in hot ashes, and then eaten with salt and oil. It is beaten up also with figs, and forms, as Hesiod assures us, a very delicate dish. It is said, too, that the asphodel, planted before the doors of a farm-house, will act as a preservative against the effects of noxious spells.

Homer, too, makes mention of the asphodel. The bulbs of it are like moderately-sized turnips, and there is no plant the root of which has more of them, as many as eighty bulbs being often grouped together. Theophrastus, and nearly all the Greek writers, with Pythagoras at the head of them, have given the name of “anthericos” to its stem, which is one cubit, and often two, in length, the leaves being very similar to those of the wild leek; it is to the root, or in other words, the bulbs, that they have given the name of asphodel. The people of our country call this plant “albucus,” and they give the name of “royal spear” to the asphodel the stem of which bears berries, thus distinguishing two varieties of it. The albucus has a stalk a cubit in length, large, naked, and smooth, in reference to which, Mago recommends that it should be cut at the end of March and the beginning of April, the period at which it blossoms, and before the seed has begun to swell; he says, too, that the stalks should be split, and exposed on the fourth day in the sun, after which, when dry, they should be made up into bundles.

The same author states, also, that the Greeks give the name of “pistana” to the aquatic plant known to us as the “sagitta;” and he recommends that it should be stripped of its bark, and dried in a mild sun, between the ides of May and the end of October. He says, too, that it is usual to cut down to the root, throughout all the month of July, the variety of the gladiolus called “cypiros,” which is a marsh-plant also, and at the end of three days to dry it in the sun, until it turns white; but that care must be taken every day to carry it under cover before sunset, the night dews being very injurious to marsh plants when cut.

CHAP. 69. (18.)

SIX VARIETIES OF THE RUSH: FOUR REMEDIES DERIVED FROM THE CYPIROS.

Mago has likewise given similar recommendations as to the rush known to us as the “mariscus,” and which is so extensively employed for weaving mats. He says that it should be gathered in the month of June, up to the middle of July, and for drying it he gives the same precepts that have been already mentioned, in the appropriate place, when speaking of sedge. He describes a second kind, also, which I find is generally called the “marine” rush, and is known to the Greeks as the “oxyschœnos.”

Generally speaking, there are three varieties of this last rush: the pointed rush, which is barren, and by the Greeks is called the male rush and the “oxys:” the female rush, which bears a black seed, and is called the “melancranis,” thicker and more bushy than the preceding one: and a third kind, called the “holoschœbnus,” which is larger still. Of these varieties, the melancranis grows separately from the others, but the oxys and the holoschœnus will grow upon the self-same clod. The holoschœnus is the most useful for all kinds of basket-work, being of a particularly supple and fleshy nature; it bears a fruit, which resembles eggs attached to one another. The rush, again, which we have spoken of as the male rush, is reproduced from itself, the summit of it being bent down into the earth; the melancranis, however, is propagated from seed. Beyond this, the roots of all the varieties of the rush die every year.

The rush is in general use for making kipes for sea-fishing, the more light and elegant kinds of basket-work, and the wicks of lamps, for which last purpose the pith is more particularly employed. In the vicinity of the maritime Alps, the rushes grow to such a vast size, that when split they measure nearly an inch in diameter; while in Egypt, on the other hand, they are so extremely fine, that the people there make sieves of them, for which, indeed, there can be nothing better.

Some authors, again, distinguish another kind of rush, of a triangular shape, to which they give the name of cypiros, though many persons make no distinction between it and the “cypiros,” in consequence of the resemblance of the names; for our own part, however, we shall observe the distinction. The cypiros, as we have already stated, is identical with the gladiolus, a plant with a bulbous root, the most esteemed being those grown in the Isle of Crete, the next best those of Naxos, and the next those of Phœnicia. The cypiros of Crete is white, with an odour strongly resembling that of nard; the produce of Naxos has a more pungent smell, that of Phœnicia but little odour of any kind, and that of Ægypt none at all for it grows in that country as well.

This plant disperses hard tumours of the body — for we shall here begin to speak of the remedies derived from the various flowers and odoriferous plants,

they being, all of them, of very considerable utility in medicine. As to the cypiros, then, I shall follow Apollodorus, who forbids it to be taken in drink, though at the same time he admits that it is extremely useful for calculi of the bladder, and recommends it in fomentations for the face. He entertains no doubt, however, that it is pro- ductive of abortion, and he mentions, as a remarkable fact, that the barbarians, by inhaling the fumes of this plant at the mouth, thereby diminish the volume of the spleen. They never go out of the house, he says, till they have inhaled these fumes, through the agency of which they daily become stronger and stronger, and more robust. He states, also, that the cypiros, employed as a liniment with oil, is an undoubted remedy for chafing of the skin, and offensive odours of the arm-pits.

Detailed table of contents

CHAP. 70.

THE CYPEROS: FOURTEEN REMEDIES. THE CYPERIS. THE CYPIRA.

The cyperos, as we have just stated, is a rush of angular shape, white near the ground, and black and solid at the top. The lower leaves are more slender than those of the leek, and those at the top are small, with the seed of the plant lying between them. The root resembles a black olive, and when it is of an oblong shape, the plant is known as the “cyperis,” being employed in medicine to a great extent. The cyperos most highly esteemed is that of the vicinity of the Temple of Jupiter Hammon, the next best being that of Rhodes, the next that of Thrsæ, and the worst of all that of Egypt, a circumstance which tends greatly to add to the misunderstanding on the subject, as that country produces the cypiros as well: but the cypiros which grows there is extremely hard, and has hardly any smell at all, while all the other varieties of it have an odour strongly resembling that of nard.

There is also an Indian plant, called the “cypira,” of a totally different character, and similar to ginger in appearance; when chewed, it has exactly the flavour of saffron.

The cyperos, employed medicinally, is possessed of certain depilatory properties. It is used in liniments for hang-nails and ulcerous sores of the genitals and of all parts of the body which are of a humid nature, ulcers of the mouth, for instance. The root of it is a very efficacious remedy for the stings of serpents and scorpions. Taken in drink, it removes obstructions of the uterus, but if employed in too large doses, it is liable to cause prolapsus of that organ. It acts also as a diuretic, and expels calculi of the bladder; properties which render it extremely useful in dropsy. It is employed topically, also, for serpiginous ulcers, those of the throat more particularly, being usually applied with wine or vinegar.

Detailed table of contents

CHAP. 71.

THE HOLOSCHÆNUS.

The root of the rush, boiled down to one third in three heminæ of water, is a cure for cough; the seed of it, parched and taken in water, arrests looseness of the bowels and the menstrual discharge, though at the same time it causes headache. The name given to this rush is holoschœnus; the parts of it nearest the root are chewed, as a cure for the bites of spiders.

I find mention made, also, of one other kind of rush, the name of which is “euripice;” the seed, they say, is narcotic, but the greatest care is necessary, not to throw the patient into a lethargy.

Detailed table of contents

CHAP. 72.

TEN REMEDIES DERIVED FROM THE SWEET-SCENTED RUSH, OR TEUCHITES.

We will also take this opportunity of mentioning the medicinal properties of the sweet-scented rush, which is found in Cœle-Syria, as already stated by us in the appropriate place The most esteemed kind, however, is that which grows in the country of the Nabatæi, and is known as the “teuchites;” the next best being the produce of Babylonia, and the very worst that of Africa, which is entirely destitute of smell. This rush is round, and when applied to the tongue, has a pungent, vinous flavour. The genuine kind, when rubbed, gives out an odour like that of the rose, and when broken asunder it is red within. It dispels flatulency, and hence it is very good for the stomach, and for persons when vomiting the bile or blood. It arrests hiccup also, promotes eructations, acts as a diuretic, and is curative of affections of the bladder. A decoction of it is used for female complaints; and in cases of opisthotony, it is applied in plasters with dry resin, these being highly valued for their warming properties.

Detailed table of contents

CHAP. 73.

REMEDIES DERIVED FROM THE FLOWERS BEFORE MENTIONED: THIRTY-TWO REMEDIES DERIVED FROM THE ROSE.

The rose is of an astringent and refreshing nature. For medicinal purposes the petals, the flowers, and the heads are used. Those portions of the petals which are quite white are known as the unglets. In the flower there is the seed, as distinguished from the filaments, and in the head there is the bud, as well as the calyx. The petals are dried, or else the juice is extracted from them, by one of the three following methods: Either the leaves are employed whole for the purpose, the unglets not being removed — for these are the parts, in fact, that contain the most juice — or else the unglets are first taken off and the residue is then macerated with oil or wine, in glass vessels placed in the sun. Some persons add salt as well, and others alkanet, or else aspalathus or sweetscented rush; as it is, when thus prepared, a very valuable remedy for diseases of the uterus and for dysentery. According to the third process, the unglets are removed from the petals, and pounded, after which they are subjected to pressure in a coarse linen cloth, the juice being received in a copper vessel; it is then boiled on a slow fire, until it has acquired the consistence of honey; for this purpose, however, the most odoriferous of the petals should be selected.

(19.) We have already stated, when speaking of the various kinds of wines, how rose wine is made. Rose juice is much used in injections for the ears, and as a gargle for ulcerations of the mouth, and for the gums and tonsils; it is employed also for the stomach, maladies of the uterus, diseases of the rectum, and for head-ache. In fevers, it is used, either by itself or in combination with vinegar, as a remedy for sleeplessness and nausea. The petals, charred, are used as a cosmetic for the eyebrows; and the thighs, when chafed, are rubbed with them dried; reduced to powder, too, they are soothing for defluxions of the eyes. The flower of the rose is soporific, and taken in oxycrate it arrests fluxes in females, the white flux in particular; also spitting of blood, and pains in the stomach, if taken in three cyathi of wine, in sufficient quantity to flavour it.

As to the seed of the rose, the best is that which is of a saffron colour, and not more than a year old; it should be dried, too, in the shade. The black seed is worthless. In cases of tooth-ache, the seed is employed in the form of a liniment; it acts also as a diuretic, and is used as a topical application for the stomach, as also in cases of erysipelas which are not inveterate: inhaled at the nostrils, it has the effect of clearing the brain. The heads of roses, taken in drink, arrest looseness of the bowels and hæmorrhage. The unglets of the rose are wholesome in cases of defluxion of the eyes; but the rose is very apt to taint all ulcerous sores of the eyes, if it is not applied at the very beginning of the defluxion, dried, and in combination with bread. The petals, too, taken internally, are extremely wholesome for gnawing pains of the stomach, and

for maladies of the abdomen or intestines; as also for the thoracic organs, if applied externally even: they are preserved, too, for eating, in a similar manner to apathum. Great care must be taken in drying rose-leaves, as they are apt to turn mouldy very quickly.

The petals, too, from which the juice has been extracted, may be put to some use when dried: powders, for instance, may be made from them, for the purpose of checking the perspiration. These powders are sprinkled on the body, upon leaving the bath, and are left to dry on it, after which they are washed off with cold water. The little excrescences of the wild rose, mixed with bears'-grease, are a good remedy for alopecia.

[Detailed table of contents](#)

CHAP. 74.

TWENTY-ONE REMEDIES DERIVED FROM THE LILY.

The roots of the lily ennoble that flower in manifold ways by their utility in a medicinal point of view. Taken in wine, they are good for the stings of serpents, and in cases of poisoning by fungi. For corns on the feet, they are applied boiled in wine, not being taken off before the end of three days. A decoction of them with grease or oil, has the effect of making the hair grow again upon burns. Taken with honied wine, they carry off corrupt blood by stool; they are good, also, for the spleen and for hernia, and act as an emmenagogue. Boiled in wine and applied with honey, they are curative of wounds of the sinews. They are good, too, for lichens, leprous sores, and scurf upon the face, and they efface wrinkles of the body.

The petals of the lily are boiled in vinegar, and applied, in combination with polium, to wounds; if it should happen, however, to be a wound of the testes, it is the best plan to apply the other ingredients with henbane and wheat-meal. Lily-seed is applied in cases of erysipelas, and the flowers and leaves are used as a cataplasm for inveterate ulcers. The juice which is extracted from the flower is called “honey” by some persons, and “syrium” by others; it is employed as an emollient for the uterus, and is also used for the purpose of promoting perspirations, and for bringing suppurations to a head.

[Detailed table of contents](#)

CHAP. 75.

SIXTEEN REMEDIES DERIVED FROM THE NARCISSUS.

Two varieties of the narcissus are employed in medicine, the one with a purple flower, and the herbaceous narcissus. This last is injurious to the stomach, and hence it is that it acts both as an emetic and as a purgative: it is prejudicial, also, to the sinews, and produces dull, heavy pains in the head: hence it is that it has received its name, from “narce,” and not from the youth Narcissus, mentioned in fable. The roots of both kinds of narcissus have a flavour resembling that of wine mixed with honey. This plant is very useful, applied to burns with a little honey, as also to other kinds of wounds, and sprains. Applied topically, too, with honey and oatmeal, it is good for tumours, and it is similarly employed for the extraction of foreign substances from the body.

Beaten up in polenta and oil it effects the cure of contusions and blows inflicted by stones; and, mixed with meal, it effectually cleanses wounds, and speedily removes black morpheus from the skin. Of this flower oil of narcissus is made, good for softening indurations of the skin, and for warming parts of the body that have been frost-bitten. It is very beneficial, also, for the ears, but is very apt to produce head-ache.

[Detailed table of contents](#)

CHAP. 76.

SEVENTEEN REMEDIES DERIVED FROM THE VIOLET.

There are both wild and cultivated violets. The purple violet is of a cooling nature: for inflammations they are applied to the stomach in the burning heats, and for pains in the head they are applied to the forehead. Violets, in particular, are used for defluxions of the eyes, prolapsus of the fundament and uterus, and suppurations. Worn in chaplets upon the head, or even smelt at, they dispel the fumes of wine and headache; and, taken in water, they are a cure for quinsy. The purple violet, taken in water, is a remedy for epilepsy, in children more particularly: violet seed is good for the stings of scorpions.

On the other hand, the flower of the white violet opens suppurations, and the plant itself disperses them. Both the white and the yellow violet check the menstrual discharge, and act as diuretics. When fresh gathered, they have less virtue, and hence it is that they are mostly used dry, after being kept a year. The yellow violet, taken in doses of half a cyathus to three cyathi of water, promotes the eatamenia; and the roots of it, applied with vinegar, assuage affections of the spleen, as also the gout. Mixed with myrrh and saffron, they are good for inflammation of the eyes. The leaves, applied with honey, cleanse ulcerous sores of the head, and, combined with cerate, they are good for chaps of the fundament and other moist parts of the body. Employed with vinegar, they effect the cure of abscesses.

[Detailed table of contents](#)

CHAP. 77.

SEVENTEEN REMEDIES DERIVED FROM THE BACCHAR. ONE REMEDY DERIVED FROM THE COMBRETUM.

The bacchar that is used in medicine is by some of our writers called the “perpressa.” It is very useful for the stings of serpents, head-ache and burning heats in the head, and for defluxions of the eyes. It is applied topically for swellings of the mamillæ after delivery, as also incipient fistulas of the eyes, and erysipelas; the smell of it induces sleep. It is found very beneficial to administer a decoction of the root for spasms, falls with violence, convulsions, and asthma. For an inveterate cough, three or four roots of this plant are boiled down to one-third; this decoction acting also as a purgative for women after miscarriage, and removing stitch in the side, and calculi of the bladder. Drying powders for perspiration are prepared also from this plant; and it is laid among garments for the smell. The combretum which we have spoken of as resembling the bacchar, beaten up with axle-grease, is a marvellous cure for wounds.

[Detailed table of contents](#)

CHAP. 78.

EIGHT REMEDIES DERIVED FROM ASARUM.

It is generally stated that asarum is good for affections of the liver, taken in doses of one ounce to a semisextarius of honied wine mixed with water. It purges the bowels like hellebore, and is good for dropsy and affections of the thoracic organs and uterus, as also for jaundice. When mixed with must, it makes a wine with strongly diuretic qualities. It is taken up as soon as it begins to put forth its leaves, and is dried in the shade. It is apt however to turn mouldy very speedily.

[Detailed table of contents](#)

CHAP. 79. (20.)

EIGHT REMEDIES DERIVED FROM GALLIC NARD.

Some authors, as we have already stated, having given the name of “field nard” to the root of the bacchar, we will here mention the medicinal properties of Gallic nard, of which we have already spoken, when treating of the foreign trees, deferring further notice of it till the present occasion. In doses of two drachmæ, taken in wine, it is good for the stings of serpents; and taken in water or in wine it is employed for inflations of the colon, maladies of the liver or kidneys, and suffusions of the gall. Employed by itself or in combination with wormwood it is good for dropsy. It has the property, also, of arresting excessive discharges of the catamenia.

Detailed table of contents

CHAP. 80.

FOUR REMEDIES DERIVED FROM THE PLANT CALLED “PHU.”

The root of the plant which we have mentioned in the same place under the name of “phu,” is given in drink, either bruised or boiled, in cases of hysterical suffocation, and for pains of the chest or sides. It acts as an emmenagogue, and is generally taken in wine.

Detailed table of contents

CHAP. 81.

TWENTY REMEDIES DERIVED FROM SAFFRON.

Saffron does not blend well with honey, or, indeed, with any sweet substance, though very readily with wine or water: it is extremely useful in medicine, and is generally kept in horn boxes. Applied with egg it disperses all kinds of inflammation, those of the eyes in particular: it is employed also for hysterical suffocations, and for ulcerations of the stomach, chest, kidneys, liver, lungs, and bladder. It is particularly useful also in cases of inflammation of those parts, and for cough and pleurisy. It likewise removes itching sensations, and acts as a diuretic. Persons who have used the precaution of first taking saffron in drink will never experience surfeit or headache, and will be proof against inebriation. Chaplets too, made of saffron, and worn on the head, tend to dispel the fumes of wine. The flower of it is employed topically with Cimolian chalk for erysipelas. It is used also in the composition of numerous other medicaments.

Detailed table of contents

CHAP. 82.

SYRIAN CROCOMAGNA: TWO REMEDIES.

There is also an eye-salve which is indebted to this plant for its name. The lees of the extract of saffron, employed in the saffron unguent known as “crocomagma,” have their own peculiar utility in cases of cataract and strangury. These lees are of a more warming nature than saffron itself; the best kind is that which, when put into the mouth, stains the teeth and saliva the colour of saffron.

Detailed table of contents

CHAP. 83.

FORTY-ONE REMEDIES DERIVED FROM THE IRIS: TWO REMEDIES DERIVED FROM THE SALIUNCA.

The red iris is better than the white one. It is very beneficial to attach this plant to the bodies of infants more particularly when they are cutting their teeth, or are suffering from cough; it is equally good, too, to inject a few drops of it when children are suffering from tape-worm. The other properties of it differ but very little from those of honey. It cleanses ulcerous sores of the head, and inveterate abscesses more particularly. Taken in doses of two drachmæ with honey, it relaxes the bowels; and an infusion of it is good for cough, gripings of the stomach, and flatulency: taken with vinegar, too, it cures affections of the spleen. Mixed with oxycrate it is good for the bites of serpents and spiders, and, in doses of two drachmæ with bread or water, it is employed for the cure of the stings of scorpions. It is applied also topically with oil to the bites of dogs, and to parts that are excoriated: employed in a similar manner, too, it is good for pains in the sinews, and in combination with resin it is used as a liniment for lumbago and sciatica. The properties of this plant are of a warming nature. Inhaled at the nostrils, it produces sneezing and cleanses the brain, and in cases of head-ache it is applied topically in combination with the quince or the strutheum. It dispels the fumes of wine also, and difficulties of breathing and taken in doses of two oboli it acts as an emetic: applied as a plaster with honey, it extracts splinters of broken bones. Powdered iris is employed also for whitlows, and, mixed with wine, for corns and warts, in which case it is left for three days on the part affected.

Chewed, it is a corrective of bad breath and offensive exhalations of the arm-pits, and the juice of it softens all kinds of indurations of the body. This plant acts as a soporific, but it wastes the seminal fluids: it is used also for the treatment of chaps of the fundament and condylomata, and it heals all sorts of excrescences on the body.

Some persons give the name of “xyris” to the wild iris. This plant disperses scrofulous sores, as well as tumours and inguinal swellings; but it is generally recommended that when wanted for these purposes it should be pulled up with the left hand, the party gathering it mentioning the name of the patient and of the disease for which it is intended to be employed. While speaking of this subject, I will take the opportunity of disclosing the criminal practices of some herbalists — they keep back a portion of the iris, and of some other plants as well, the plantago for instance, and, if they think that they have not been sufficiently well paid and wish to be employed a second time, bury the part they have kept back in the same place; their object being, I suppose, to revive the malady which has just been cured.

The root of the saliunca boiled in wine, arrests vomiting and strengthens the stomach.

CHAP. 84.

EIGHTEEN REMEDIES DERIVED FROM THE POLIUM.

Those persons, according to Musæus and Hesiod, who are desirous of gaining honour and glory, should rub the body all over with polium, and handle and cultivate it as much as possible. They say, too, that it should be kept about the person as an antidote to poison, and that to keep serpents away it should be strewed beneath the bed, burnt, or else carried on the person; decoctions of it in wine, either fresh-gathered or dried, should be used too as a liniment for the body. Medical men prescribe it in vinegar for affections of the spleen, and in wine for the jaundice; a decoction of it in wine is recommended also for incipient dropsy; and in this way too, it is employed as a liniment for wounds. This plant has the effect of bringing away the after-birth and the dead foetus, and of dispelling pains in various parts of the body: it empties the bladder also, and is employed in liniments for defluxions of the eyes. In- deed, there is no plant known that better deserves to form an ingredient in the medicament known to us as the “alexipharmacon:” though there are some who say that it is injurious to the stomach and is apt to stuff the head, and that it produces abortion — assertions which others, again, totally deny.

There is a superstitious observance also, to the effect that, for cataract, it ought to be attached to the neck the moment it is found, every precaution being taken not to let it touch the ground. The same persons state too that the leaves of it are similar to those of thyme, except that they are softer and more white and downy. Beaten up with wild rue in rain water, it is said to assuage the pain of the sting of the asp; it is quite as astringent too as the flower of the pomegranate, and as efficacious for closing wounds and preventing them from spreading.

[Detailed table of contents](#)

CHAP. 85.

THREE REMEDIES DERIVED FROM THE HOLOCHRY SOS. SIX REMEDIES
DERIVED FROM THE CHRYSOCOME.

The holochrysos, taken in wine, is a cure for strangury, and it is employed in liniments for defluxions of the eyes. Mixed with burnt lees of wine and polenta, it is curative of lichens.

The root of the chrysocome is warming and astringent; it is taken in drink for affections of the liver and lungs, and a decoction of it in hydromel is good for pains of the uterus. It acts as an emmenagogue also, and, administered raw, draws off the water in dropsy.

Detailed table of contents

CHAP. 86.

TWENTY-ONE REMEDIES DERIVED FROM MELISSOPHYLLUM.

If the bee-hives are rubbed all over with melissophyllum or melittæna, the bees will never desert them; for there is no flower in which they take greater delight. If branches of this plant are used, the bees may be kept within bounds without any difficulty. It is an excellent remedy, also, for the stings of bees, wasps, and similar insects, as also for wounds made by spiders and scorpions; it is used, too, for hysterical suffocations, in combination with nitre, and for gripings of the bowels, with wine. The leaves of it are employed topically for scrofulous sores, and, in combination with salt, for maladies of the fundament. A decoction of the juice promotes the menstrual discharge, dispels inflammations, and heals ulcerous sores: it is good, too, for diseases of the joints and the bites of dogs, and is beneficial in cases of inveterate dysentery, and for cœliac affections, hardness of breathing, diseases of the spleen, and ulcerations of the thoracic organs. For films on the eyes, it is considered a most excellent plan to anoint them with the juice of this plant mixed with honey.

Detailed table of contents

CHAP. 87.

THIRTEEN REMEDIES DERIVED FROM THE MELILOTE.

The melilote, again, applied with the yolk of an egg, or else linseed, effects the cure of diseases of the eyes. It assuages pains, too, in the jaws and head, applied with rose oil; and, employed with raisin wine, it is good for pains in the ears, and all kinds of swellings or eruptions on the hands. A decoction of it in wine, or else the plant itself beaten up raw, is good for pains in the stomach. It is equally beneficial, too, for maladies of the uterus; and for diseases of the testes, prolapsus of the fundament, and all other diseases of those parts, a decoction is made of it, fresh-gathered, in water or in raisin wine. With the addition of rose oil, it is used as a liniment for carcinoma. Boiled in sweet wine, it is particularly useful for the treatment of the ulcers known as “melicerides.”

Detailed table of contents

CHAP. 88. (21.)

FOUR REMEDIES DERIVED FROM TREFOIL.

The trefoil, I know, is generally looked upon as being particularly good for the stings of serpents and scorpions, the seed being taken in doses of twenty grains, with either wine or oxycrate; or else the leaves and the plant itself are boiled together, and a decoction made of them; indeed, it is stated, that a serpent is never to be seen among trefoil. Celebrated authors, too, I find, have asserted that twenty-five grains of the seed of the kind of trefoil which we have spoken of as the “minyanthes,” are a sufficient antidote for all kinds of poisons: in addition to which, there are numerous other remedial virtues ascribed to it.

But these notions, in my opinion, are counterbalanced by the authority of a writer of the very highest repute: for we find the poet Sophocles asserting that the trefoil is a venomous plant. Simus, too, the physician, maintains that a decoction of it, or the juice, poured upon the human body, is productive of burning sensations similar to those experienced by persons when they have been stung by a serpent and have trefoil applied to the wound. It is my opinion, then, that trefoil should never be used in any other capacity than as a counter-poison; for it is not improbable that the venom of this plant has a natural antipathy to all other kinds of poisons, a phænomenon which has been observed in many other cases as well. I find it stated, also, that the seed of the trefoil with an extremely diminutive leaf, applied in washes to the face, is extremely beneficial for preserving the freshness of the skin in females.

Detailed table of contents

CHAP. 89.

TWENTY-EIGHT REMEDIES DERIVED FROM THYME.

Thyme should be gathered while it is in flower, and dried in the shade. There are two kinds of thyme: the white thyme with a ligneous root, which grows upon declivities, and is the most esteemed of the two, and another variety, which is of a darker colour, and bears a swarthy flower. They are, both of them, considered to be extremely beneficial to the sight, whether used as an article of food or as a medicament, and to be good for inveterate coughs. Used as an electuary, with vinegar and salt, they facilitate expectoration, and taken with honey, they prevent the blood from coagulating. Applied externally with mustard, they dispel chronic fluxes of the fauces, as well as various affections of the stomach and bowels. Still, however, these plants must be used in moderation, as they are of a heating nature, for which reason it is that they act so astringently upon the bowels. In cases of ulceration of the intestines, the dose should be one denarius of thyme to one sextarius of oxymel; the same proportions, too, should be taken for pains in the sides, between the shoulder-blades, or in the thoracic organs. Taken with oxymel, these plants are used for the cure of intestinal diseases, and a similar draught is administered in cases of alienation of the senses and melancholy.

Thyme is given also for epilepsy, when the fits come on, the smell of it reviving the patient; it is said, too, that epileptic persons should sleep upon soft thyme. It is good, also, for hardness of breathing, and for asthma and obstructions of the catamenia. A decoction of thyme in water, boiled down to one-third, brings away the dead fœtus, and it is given to males with oxymel, as a remedy for flatulency, and in cases of swelling of the abdomen or testes and of pains in the bladder. Applied with wine, it removes tumours and fluxes, and, in combination with vinegar, callosities and warts. Mixed with wine, it is used as an external application for sciatica; and, beaten up with oil and sprinkled upon wool, it is employed for diseases of the joints, and for sprains. It is applied, also, to burns, mixed with hogs' lard. For maladies of the joints of recent date, thyme is administered in drink, in doses of three oboli to three cyathi of oxymel. For loss of appetite, it is given, beaten up with salt.

Detailed table of contents

CHAP. 90.

FOUR REMEDIES DERIVED FROM THE HEMEROCALLES.

The hemerocalles has a soft, pale green leaf, with an odoriferous, bulbous root. This root, applied with honey to the abdomen, draws off the aqueous humours and all corrupt blood. The leaves of it are applied for defluxions of the eyes, and for pains in the mamillæ, after childbirth.

Detailed table of contents

CHAP. 91.

FIVE REMEDIES DERIVED FROM THE HELENIUM.

The helenium, which springs, as we have already stated, from the tears of Helena, is generally thought to have been produced for improving the appearance, and to maintain unimpaired the freshness of the skin in females, both of the face and of other parts of the body. Besides this, it is generally supposed that the use of it confers additional graces on the person, and ensures universal attraction. They say, too, that, taken with wine, it promotes gaiety of spirit, having, in fact, a similar effect to the nepenthes, which has been so much vaunted by Homer, as producing forgetfulness of all sorrow. The juice of this plant is remarkably sweet, and the root of it, taken fasting in water, is good for hardness of breathing; 'it is white within, and sweet. An infusion of it is taken in wine for the stings of serpents; and the plant, bruised, it is said, will kill mice.

[Detailed table of contents](#)

CHAP. 92.

TWENTY-TWO REMEDIES DERIVED FROM THE ABROTONUM.

We find two varieties of abrotonum mentioned, the field, and the mountain kind; this last, it is generally understood, is the female plant, the other the male. They are both of them bitter, like wormwood. That of Sicily is the most esteemed, and next to it, that of Galatia. The leaves of it are sometimes employed, but it is the seed that possesses the most warming properties; hence it is, that it is so beneficial for maladies of the sinews, for cough, hardness of breathing, convulsions, ruptures, lumbago, and strangury. Several handfuls of this plant are boiled down to one-third, and the decoction of it, in doses of four cyathi, is administered in drink. The seed is given, pounded, in water, in doses of one drachma; it is very good for affections of the uterus.

Mixed with barley-meal, this plant brings tumours to a head, and boiled with quinces, it is employed as a liniment for inflammations of the eyes. It keeps away serpents, and for their stings it is either taken in wine, or else employed in combination with it as a liniment. It is extremely efficacious, also, for the stings of those noxious insects by which shivering fits and chills are produced, such as the scorpion and the spider called “phalangium,” for example; taken in a potion, it is good for other kinds of poison, as also for shivering fits, however produced, and for the extraction of foreign substances adhering to the flesh; it has the effect, also, of expelling intestinal worms. It is stated that a sprig of this plant, if put beneath the pillow, will act as an aphrodisiac, and that it is of the very greatest efficacy against all those charms and spells by which impotence is produced.

Detailed table of contents

CHAP. 93. (22.)

ONE REMEDY DERIVED FROM THE LEUCANTHEMUM. NINE REMEDIES
DERIVED FROM THE AMARACUS.

The leucanthemum, mixed with two-thirds of vinegar, is curative of asthma. The sampsuchum or amaracus, — that of Cyprus being the most highly esteemed, and possessed of the finest smell — is a remedy for the stings of scorpions, applied to the wound with vinegar and salt. Used as a pessary, too, it is very beneficial in cases of menstrual derangement; but when taken in drink, its properties are not so powerfully developed. Used with polenta, it heals defluxions of the eyes; and the juice of it, boiled, dispels gripings of the stomach. It is useful, too, for strangury and dropsy; and in a dry state, it promotes sneezing. There is an oil extracted from it, known as “sampsuchinum,” or “amaracinum,” which is very good for warming and softening the sinews; it has a warming effect, also, upon the uterus. The leaves are good for bruises, beaten up with honey, and, mixed with wax, for sprains.

Detailed table of contents

CHAP. 94. (23.)

TEN REMEDIES DERIVED FROM THE ANEMONE OR PHRENION.

We have as yet spoken only of the anemone used for making chaplets; we will now proceed to describe those kinds which are employed for medicinal purposes. Some persons give the name of “phrenion” to this plant: there are two species of it; one of which is wild, and the other grows on cultivated spots; though they are, both of them, attached to a sandy soil. Of the cultivated anemone there are numerous varieties; some, and these are the most abundant, have a scarlet flower, while others, again, have a flower that is purple or else milk-white. The leaves of all these three kinds bear a strong resemblance to parsley, and it is not often that they exceed half a foot in height, the head being very similar to that of asparagus. The flower never opens, except while the wind is blowing, a circumstance to which it owes its name. The wild anemone is larger than the cultivated one, and has broader leaves, with a scarlet flower.

Some persons erroneously take the wild anemone to be the same as the argemone, while others, again, identify it with the poppy which we have mentioned under the name of “rhœas:” there is, however, a great difference between them, as these two other plants blossom later than the anemone, nor does the anemone possess a juice or a calyx like theirs; besides which, it terminates in a head like that of asparagus.

The various kinds of anemone are good for pains and inflammations of the head, diseases of the uterus, and stoppage of the milk in females; taken, too, in a ptisan, or applied as a pessary in wool, they promote the menstrual discharge. The root, chewed, has a tendency to bring away the phlegm, and is a cure for tooth-ache: a decoction of it is good, too, for defluxions of the eyes, and effaces the scars left by wounds. The Magi have attributed many very wonderful properties to these plants: they recommend it to be gathered at the earliest moment in the year that it is seen, and certain words to be repeated, to the effect that it is being gathered as a remedy for tertian and quartan fevers; after which the flower must be wrapped up in red cloth and kept in the shade, in order to be attached to the person when wanted. The root of the anemone with a scarlet flower, beaten up and applied to the body of any animated being, produces an ulcer there by the agency of its acrid qualities; hence it is that it is so much employed as a detergent for ulcerous sores.

CHAP. 95. (24.)

SIX REMEDIES DERIVED FROM THE CENANTHE.

The cenanthe is a plant which is found growing upon rocks, has the leaf of the parsnip, and a large root with numerous fibres. The stalk of it and the leaves, taken with honey and black wine, facilitate delivery and bring away the after-birth: taken with honey, also, they are a cure for cough, and act as a powerful diuretic. The root of this plant is curative of diseases of the bladder.

Detailed table of contents

CHAP. 96. (25.)

ELEVEN REMEDIES DERIVED FROM THE HELICHRYSOS.

The helichrysos is by some persons called the “chrysanthemon. It has small, white branches, with leaves of a whitish colour, similar to those of the abrotonum. The clusters, disposed around it, and glistening like gold in the rays of the sun, are never known to fade; hence it is that they make chaplets of it for the gods, a custom which was most faithfully observed by Ptolemæus, the king of Egypt. This plant grows in shrubberies: taken in wine, it acts as a diuretic and emmenagogue, and, in combination with honey, it is employed topically for burns. It is taken also in potions for the stings of serpents, and for pains in the loins; and, with honied wine, it removes coagulated blood in the abdominal regions and the bladder. The leaves of it, beaten up and taken in doses of three oboli, in white wine, arrest the menstrual discharge when in excess.

The smell of this plant is far from disagreeable, and hence it is kept with clothes, to protect them from the attacks of vermin.

Detailed table of contents

CHAP. 97. (26.)

EIGHT REMEDIES DERIVED FROM THE HYACINTH.

The hyacinth grows in Gaul more particularly, where it is employed for the dye called “hysginum.” The root of it is bulbous, and is well known among the dealers in slaves: applied to the body, with sweet wine, it retards the signs of puberty, and prevents them from developing themselves. It is curative, also, of gripings of the stomach, and of the bites of spiders, and it acts as a diuretic. The seed is administered, with abrotonum, for the stings of serpents and scorpions, and for jaundice.

[Detailed table of contents](#)

CHAP. 98.

SEVEN REMEDIES DERIVED FROM THE LYCHNIS.

The seed of the lychnis, too, which is just the colour of fire, is beaten up and taken in drink for the stings of serpents, scorpions, hornets, and other insects of similar nature: the wild variety, however, is prejudicial to the stomach. It acts as a laxative to the bowels; and, taken in doses of two drachmæ, is remarkably efficacious for carrying off the bile. So extremely baneful is it to scorpions, that if they so much as see it, they are struck with torpor. The people of Asia call the root of it “bolites,” and they say that if it is attached to the body it will effectually disperse albugo.

Detailed table of contents

CHAP. 99. (27.)

FOUR REMEDIES DERIVED FROM THE VINCAPERVINCA.

The vincapervinca, too, or chamædaphne, is dried and pounded, and given to dropsical patients in water, in doses of one spoonful; a method of treatment which speedily draws off the water. A decoction of it, in ashes, with a sprinkling of wine, has the effect of drying tumours: the juice, too, is employed as a remedy for diseases of the ears. Applied to the regions of the stomach, this plant is said to be remarkably good for diarrhœa.

Detailed table of contents

CHAP. 100.

THREE REMEDIES DERIVED FROM BUTCHER'S BROOM.

A decoction of the root of butcher's broom is recommended to be taken every other day for calculus in the bladder, strangury, and bloody urine. The root, however, should be taken up one day, and boiled the next, the proportion of it being one sextarius to two cyathi of wine. Some persons beat up the root raw, and take it in water: it is generally considered, too, that there is nothing in existence more beneficial to the male organs than the young stalks of the plant, beaten up and used with vinegar.

[Detailed table of contents](#)

CHAP. 101.

TWO REMEDIES DERIVED FROM THE BATIS.

The batis, too, relaxes the bowels, and, beaten up raw, it is employed topically for the gout. The people of Egypt cultivate the acinos, too, both as an article of food and for making chaplets. This plant would be the same thing as ocimum, were it not that the leaves and branches of it are rougher, and that it has a powerful smell. It promotes the catamenia, and acts as a diuretic.

Detailed table of contents

CHAP. 102. (28.)

TWO REMEDIES DERIVED FROM THE COLOCASIA.

The colocasia, according to Glaucias, softens the acridity of humours of the body, and is beneficial to the stomach.

[Detailed table of contents](#)

CHAP. 103. (29.)

SIX REMEDIES DERIVED FROM THE ANTHYLLIUM OR ANTHYLLUM.

The people of Egypt eat the anthalium, but I cannot find that they make any other use of it; but there is another plant called the “anthyllium,” or, by some persons, the “anthyllum,” of which there are two kinds: one, similar in its leaves and branches to the lentil, a palm in height, growing in sandy soils exposed to the sun, and of a somewhat saltish taste; the other, bearing a strong resemblance to the chamæpitys, but smaller and more downy, with a purple flower, a strong smell, and growing in stony spots.

The first kind, mixed with rose-oil and applied with milk, is extremely good for affections of the uterus and all kinds of sores: it is taken as a potion for strangury and gravel in the kidneys, in doses of three drachmæ. The other kind is taken in drink, with oxymel, in doses of four drachmæ, for indurations of the uterus, gripings of the bowels, and epilepsy.

[Detailed table of contents](#)

CHAP. 104. (30.)

EIGHT REMEDIES DERIVED FROM THE PARTHENIUM, LEUCANTHES, OR AMARACUS.

The parthenium is by some persons called the “leucanthes,” and by others the “amaracus.” Celsus, among the Latin writers, gives it the names of “perdicium” and “muralis.” It grows in the hedge-rows of gardens, and has the smell of an apple, with a bitter taste. With the decoction of it, fomentations are made for maladies of the fundament, and for inflammations and indurations of the uterus: dried and applied with honey and vinegar, it carries off black bile, for which reason it is considered good for vertigo and calculus in the bladder. It is employed as a liniment, also, for erysipelas, and, mixed with stale axle-grease, for scrofulous sores. For tertian fevers the Magi recommend that it should be taken up with the left hand, it being mentioned at the time for whom it is gathered, care being also taken not to look back while doing so: a leaf of it should be laid beneath the patient’s tongue, after which it must be eaten in a cyathus of water.

Detailed table of contents

CHAP. 105. (31.)

EIGHT REMEDIES DERIVED FROM THE STRYCHNUM OR STRYCHNUM, HALICACABUM, CALLIAS, DORCYNION, MANICON, NEURAS, MORIO, OR MOLY.

The trychnon is by some called “strychnon;” I only wish that the garland-makers of Egypt would never use this plant in making their chaplets, being deceived as they are by the resemblance in the leaves of both kinds to those of ivy. One of these kinds, bearing scarlet berries with a stone, enclosed in follicles, is by some persons called the “halicacabum,” by others the “callion,” and by the people of our country, the “vesicaria,” from the circumstance of its being highly beneficial to the bladder and in cases of calculus.

The trychnon is more of a woody shrub than a herb, with large follicles, broad and turbinate, and a large berry within, which ripens in the month of November. A third kind, again, has a leaf resembling that of ocimum — but it is not my intention to give an exact description of it, as I am here speaking of remedies, and not of poisons; for a few drops of the juice, in fact, are quite sufficient to produce insanity. The Greek writers, however, have even turned this property into matter for jesting; for, according to them, taken in doses of one drachma, this plant is productive of delusive and prurient fancies, and of vain, fantastic visions, which vividly present all the appearance of reality: they say, too, that if the dose is doubled, it will produce downright madness, and that any further addition to it, will result in instant death.

This is the same plant which the more well-meaning writers have called in their innocence “dorycnion,” from the circumstance that weapons used in battle are poisoned with it — for it grows everywhere — while others, again, who have treated of it more at length, have given it the surname of “manicon.” Those, on the other hand, who have iniquitously concealed its real qualities, give it the name of “erythron” or “neuras,” and others “perisson” — details, however, which need not be entered into more fully, except for the purpose of putting persons upon their guard.

There is another kind, again, also called “halicacabum,” which possesses narcotic qualities, and is productive of death even more speedily than opium: by some persons it is called “morio,” and by others “moly.” It has, however, been highly extolled by Diocles and Evenor, and, indeed, Timaristus has gone so far as to sing its praises in verse. With a wonderful obliviousness of remedies really harmless, they tell us, forsooth, that it is an instantaneous remedy for loose teeth to rinse them with halicacabum steeped in wine: but at the same time they add the qualification that it must not be kept in the mouth too long, or else delirium will be the result. This, however, is pointing out remedies with a vengeance, the employment of which will be attended with worse results than the malady itself.

There is a third kind of halicacabum, that is esteemed as an article of food;

but even though the flavour of it may be preferred to garden plants, and although Xenocrates assures us that there is no bodily malady for which the trychnos is not highly beneficial, they are none of them so valuable as to make me think it proper to speak more at length upon the subject, more particularly as there are so many other remedies, which are unattended with danger. Persons who wish to pass themselves off for true prophets, and who know too well how to impose upon the superstitions of others, take the root of the halicacabum in drink. The remedy against this poison — and it is with much greater pleasure that I state it — is to drink large quantities of honied wine made hot. I must not omit the fact, too, that this plant is naturally so baneful to the asp, that when the root is placed near that reptile, the very animal which kills others by striking them with torpor, is struck with torpor itself; hence it is, that, beaten up with oil, it is used as a cure for the sting of the asp.

Detailed table of contents

CHAP. 106.

SIX MEDICINES DERIVED FROM THE CORCHORUS.

The corchorus is a plant which is used at Alexandria as an article of food: the leaves of it are rolled up, one upon the other, like those of the mulberry, and it is wholesome, it is said, for the viscera, and in cases of alopecy, being good also for the removal of freckles. I find it stated also, that it cures the scab in cattle very rapidly: and, according to Nicander, it is a remedy for the stings of serpents, it gathered before it blossoms.

Detailed table of contents

CHAP. 107.

THREE REMEDIES DERIVED FROM THE CNECOS.

There would be no necessity to speak at any length of the cencos or atractylis, an Egyptian plant, were it not for the fact that it offers a most efficacious remedy for the stings of veno- mous animals, as also in cases of poisoning by fungi. It is a well-known fact, that persons, when stung by the scorpion, are not sensible of any painful effects so long as they hold this plant in their hand.

Detailed table of contents

CHAP. 108. (33.)

ONE REMEDY DERIVED FROM THE PESOLUTA.

The Egyptians also cultivate the pesoluta in their gardens, for chaplets. There are two kinds of this plant, the male and the female: either of them, it is said, placed beneath the person, when in bed, acts as an antaphrodisiac, upon the male sex more particularly.

Detailed table of contents

CHAP. 109. (34.)

AN EXPLANATION OF GREEK TERMS RELATIVE TO WEIGHTS AND MEASURES.

As we have occasion to make use of Greek names very frequently when speaking of weights and measures, I shall here subjoin, once for all, some explanation of them.

The Attic drachma — for it is generally the Attic reckoning that medical men employ — is much the same in weight as the silver denarius, and is equivalent to six oboli, the obolus being ten chalci; the cyathus is equal in weight to ten drachmæ. When the measure of an acetabulum is spoken of, it is the same as one fourth part of a hemina, or fifteen drachmæ in weight. The Greek mna, or, as we more generally call it, “mina,” equals one hundred Attic drachmæ in weight.

Summary. — Remedies, narratives, and observations, seven hundred and thirty.

Roman Authors Quoted. — Cato the Censor, M. Varro, Antias, Cæpio, Vestinus, Vibius Rufus, Hyginus, Pomponius Mela, Pompeius Lennæus, Cornelius Celsus, Calpurnius Bassus, C. Valgius, Licinius Macer, Sextius Niger who wrote in Greek, Julius Bassus who wrote in Greek, Autonius Castor.

Foreign Authors Quoted. — Theophrastus, Democritus, Orpheus, Pythagoras, Mago, Menander who wrote the Biochresta, Nicander, Homer, Hesiod, Musmæus, Sophocles, Anaxilaüs.

Medical Authors Quoted. — Mnesitheus who wrote on Chaplets, Callimachus who wrote on Chaplets, Phantias the physician, Simus, Timaristus, Hippocrates, Chrysippus, Diocles, Ophelion, Hieraclides, Hicesius, Dionysius, Apollodorus of Citium, Apollodorus of Tarentum, Praxagoras, Plistonius, Medius, Dieuches, Cleophrantus, Philistio, Asclepiades, Crateaus, Petronius Diodotus, Iollas, Erasistratus, Diagoras, Andreas, Mnesides, Epicharmus, Damon, Dalion, Sosimenes, Tlepolemus, Metrodorus, Solo, Lyeus, Olympias of Thebes, Philinus, Petrichus Micton, Glaucias, Xenocrates.

Detailed table of contents

**BOOK XXII. THE PROPERTIES OF PLANTS AND
FRUITS.**

Detailed table of contents

CHAP. 1.

THE PROPERTIES OF PLANTS.

Nature and the earth might have well filled the measure of our admiration, if we had nothing else to do but to consider the properties enumerated in the preceding Book, and the numerous varieties of plants that we find created for the wants or the enjoyment of mankind. And yet, how much is there still left for us to describe, and how many discoveries of a still more astonishing nature! The greater part, in fact, of the plants there mentioned recommend themselves to us by their taste, their fragrance, or their beauty, and so invite us to make repeated trials of their virtues: but, on the other hand. the properties of those which remain to be described, furnish us with abundant proof that nothing has been created by Nature without some purpose to fulfil, unrevealed to us though it may be.

Detailed table of contents

CHAP. 2. (1.)

PLANTS USED BY NATIONS FOR THE ADORNMENT OF THE PERSON.

I remark, in the first place, that there are some foreign nations which, in obedience to long-established usage, employ certain plants for the embellishment of the person. That, among some barbarous peoples, the females stain the face by means of various plants, there can be little doubt, and among the Daci and the Sarmatæ we find the men even marking their bodies. There is a plant in Gaul, similar to the plantago in appearance, and known there by the name of “glastum:” with it both matrons and girls among the people of Britain are in the habit of staining the body all over, when taking part in the performance of certain sacred rites; rivalling hereby the swarthy hue of the Æthiopians, they go in a state of nature.

Detailed table of contents

CHAP. 3. (2.)

EMPLOYMENT OF PLANTS FOR DYEING. EXPLANATION OF THE TERMS SAGMEN, VERBENA, AND CLARIGATIO.

We know, too, that from plants are extracted admirable colours for dyeing; and, not to mention the berries of Galatia, Africa, and Lusitania, which furnish the coccus, a dye reserved for the military costume of our generals, the people of Gaul beyond the Alps produce the Tyrian colours, the conchyliated, and all the other hues, by the agency of plants alone. They have not there to seek the murex at the bottom of the sea, or to expose themselves to be the prey of the monsters of the deep, while tearing it from their jaws, nor have they to go searching in depths to which no anchor has penetrated — and all this for the purpose of finding the means whereby some mother of a family may appear more charming in the eyes of her paramour, or the seducer may make himself more captivating to the wife of another man. Standing on dry land, the people there gather in their dyes just as we do our crops of corn — though one great fault in them is, that they wash out; were it not for which, luxury would have the means of bedecking itself with far greater magnificence, or, at all events, at the price of far less danger.

It is not my purpose, however, here to enter further into these details, nor shall I make the attempt, by substituting resources attended with fewer risks, to circumscribe luxury within the limits of frugality; though, at the same time, I shall have to speak on another occasion how that vegetable productions are employed for staining stone and imparting their colours to walls. Still, however, I should not have omitted to enlarge upon the art of dyeing, had I found that it had ever been looked upon as forming one of our liberal arts. Meantime, I shall be actuated by higher considerations, and shall proceed to show in what esteem we are bound to hold the mute plants even, or in other words, the plants of little note. For, indeed, the authors and founders of the Roman sway have derived from these very plants even almost boundless results; as it was these same plants, and no others, that afforded them the “sagmen,” employed in seasons of public calamity, and the “verbena” of our sacred rites and embassies. These two names, no doubt, originally signified the same thing, — a green turf torn up from the citadel with the earth attached to it; and hence, when envoys were dispatched to the enemy for the purpose of clarification, or, in other words, with the object of *clearly* demanding restitution of property that had been carried off, one of these officers was always known as the “verbenarius.”

CHAP. 4. (3.)

THE GRASS GROWN: HOW RARELY IT HAS BEEN AWARDED.

Of all the crowns with which, in the days of its majesty, the all-sovereign people, the ruler of the earth, recompensed the valour of its citizens, there was none attended with higher glory than the crown of grass. The crowns bedecked with gems of gold, the vallar, mural, rostrate, civic, and triumphal crowns, were, all of them, inferior to this: great, indeed, was the difference between them, and far in the background were they thrown by it. As to all the rest, a single individual could confer them, a general or commander on his soldiers for instance, or, as on some occasions, on his colleague: the senate, too, exempt from the cares and anxieties of war, and the people in the enjoyment of repose, could award them, together with the honours of a triumph.

(4.) But as for the crown of grass, it was never conferred except at a crisis of extreme desperation, never voted except by the acclamation of the whole army, and never to any one but to him who had been its preserver. Other crowns were awarded by the generals to the soldiers, this alone by the soldiers, and to the general. This crown is known also as the “obsidional” crown, from the circumstance of a beleaguered army being delivered, and so preserved from fearful disaster. If we are to regard as a glorious and a hallowed reward the civic crown, presented for preserving the life of a single citizen, and him, perhaps, of the very humblest rank, what, pray, ought to be thought of a whole army being saved, and indebted for its preservation to the valour of a single individual?

The crown thus presented was made green grass, gathered on the spot where the troops so rescued had been beleaguered. Indeed, in early times, it was the usual token of victory for the vanquished to present to the conqueror a handful of grass; signifying thereby that they surrendered their native soil, the land that had nurtured them, and the very right even there to be interred — a usage which, to my own knowledge, still exists among the nations of Germany.

Detailed table of contents

CHAP. 5. (5.)

THE ONLY PERSONS THAT HAVE BEEN PRESENTED WITH THIS CROWN.

L. Siccus Dentatus was presented with this crown but once, though he gained as many as fourteen civic crowns, and fought one hundred and twenty battles, in all of which he was victorious — so rarely is it that an army has to thank a single individual only for its preservation! Some generals, however, have been presented with more than one of these crowns, P. Decius Mus, the military tribune, for example, who received one from his own army, and another from the troops which he had rescued when surrounded. He testified by an act of devoutness in what high esteem he held such an honour as this, for, adorned with these insignia, he sacrificed a white ox to Mars, together with one hundred red oxen, which had been presented to him by the beleaguered troops as the recompense of his valour: it was this same Decius, who afterwards, when consul, with Imperator for his colleague, devoted his life to secure victory to his fellow-citizens.

This crown was presented also by the senate and people of Rome — a distinction than which I know of nothing in existence more glorious — to that same Fabius who restored the fortunes of Rome by avoiding a battle; not, however, on the occasion when he preserved the master of the horse and his army; for then it was deemed preferable by those who were indebted to him for their preservation to present him with a crown under a new title, that of “father.” The crown of grass was, however, awarded to him, with that unanimity which I have mentioned, after Hannibal had been expelled from Italy; being the only crown, in fact, that has hitherto been placed upon the head of a citizen by the hands of the state itself, and, another remarkable distinction, the only one that has ever been conferred by the whole of Italy united.

Detailed table of contents

CHAP. 6. (6.)

THE ONLY CENTURION THAT HAS BEEN THUS HONOURED.

In addition to the persons already mentioned, the honour of this crown has been awarded to M. Calpurnius Flamma, then a military tribune in Sicily; but up to the present time it has been given to a single centurion only, Cneius Petreius Atinas, during the war with the Cimbri. This soldier, while acting as primipilus under Catulus, on finding all retreat for his legion cut off by the enemy, harangued the troops, and after slaying his tribune who hesitated to cut a way through the encampment of the enemy, brought away the legion in safety. I find it stated also by some authors, that, in addition to this honour, this same Petreius, clad in the prætexta, offered sacrifice at the altar, to the sound of the pipe, in presence of the then consuls, Marius and Catulus.

The Dictator Sylla has also stated in his memoirs, that when legatus in the Marsic War he was presented with this crown by the army, at Nola; an event which he caused to be commemorated in a painting at his Tusculan villa, which afterwards became the property of Cicero. If there is any truth in this statement, I can only say that it renders his memory all the more execrable, and that, by his proscriptions, with his own hand he tore this crown from his brow, for few indeed were the citizens whom he thus preserved, in comparison with those he slaughtered at a later period. And let him even add to this high honour his proud surname of “Felix,” if he will; all the glories of this crown he surrendered to Sertorius, from the moment that he put his proscribed fellow-citizens in a stage of siege throughout the whole world.

Varro, too, relates that Scipio Æmilianus was awarded the obsidional crown in Africa, under the consul Manilius, for the preservation of three cohorts, by bringing as many to their rescue; an event commemorated by an inscription upon the base of the statue erected in honour of him by the now deified Emperor Augustus, in the Forum which bears his name. Augustus himself was also presented by the senate with the obsidional crown, upon the ides of September, in the consulship of M. Cicero the Younger, the civic crown being looked upon as not commensurate with his deserts. Beyond these, I do not find any one mentioned as having been rewarded with this honour.

Detailed table of contents

CHAP. 7.

REMEDIES DERIVED FROM OTHER CHAPLET PLANTS.

No plant in particular was employed in the composition of this crown, such only being used as were found growing on the spot so imperilled; and thus did they become the means, however humble and unnoted themselves, of conferring high honour and renown. All this, however, is but little known among us at the present day; a fact which I am the less surprised at, when I reflect that those plants even are treated with the same indifference, the purpose of which it is to preserve our health, to allay our bodily pains, and to repel the advances of death! And who is there that would not visit with censure, and justly visit, the manners of the present day? Luxury and effeminacy have augmented the price at which we live, and never was life more hankered after, or worse cared for, than it is at present. This, however, we look upon as the business of others, forsooth; other persons must see to it, without our troubling ourselves to request them, and the physicians must exercise the necessary providence in our behalves. As for ourselves, we go on enjoying our pleasures, and are content to live — a thing that in my opinion reflects the highest possible disgrace — by putting faith in others.

Nay, even more than this, we ourselves are held in derision by many, for undertaking these researches, and are charged with busying ourselves with mere frivolities! It is some solace, however, in the prosecution of these our boundless labours, to have Nature as our sharer in this contempt: Nature who, as we will prove beyond a doubt, has never failed in coming to the assistance of man, and has implanted remedies for our use in the most despised even of the vegetable productions, medicaments in plants which repel us with their thorns.

It is of these, in fact, that it remains for us now to speak, as next in succession to those which we have mentioned in the preceding Book; and here we cannot sufficiently admire, and, indeed, adore, the wondrous providence displayed by Nature. She had given us, as already shewn, plants soft to the touch, and agreeable to the palate; in the flowers she had painted the remedies for our diseases with her varied tints, and, while commingling the useful with the delicious, had attracted our attention by means of the pleasures of the eye. Here, however, she has devised another class of plants, bristling and repulsive to the sight, and dangerous to the touch; so much so, indeed, that we fancy we all but hear the voice of her who made them as she reveals to us her motives for so doing. It is her wish, she says, that no ravening cattle may browse upon them, that no wanton hand may tear them up, that no heedless footstep may tread them down, that no bird, perching there, may break them: and in thus fortifying them with thorns, and arming them with weapons, it has been her grand object to save and protect the remedies which they afford to

man. Thus we see, the very qualities even which we hold in such aversion, have been devised by Nature for the benefit and advantage of mankind.

Detailed table of contents

CHAP. 8. (7.)

THE ERYNGE OR ERYNGIUM.

In the first rank of the plants armed with prickles, the erynge, or eryngion stands pre-eminent, a vegetable production held in high esteem as an antidote formed for the poison of serpents and all venomous substances. For stings and bites of this nature, the root is taken in wine in doses of one drachma, or if, as generally is the case, the wound is attended with fever, in water. It is employed also, in the form of a liniment, for wounds, and is found to be particularly efficacious for those inflicted by water-snakes or frogs. The physician Heraclides states it as his opinion that, boiled in goose-broth, it is a more valuable remedy than any other known, for aconite and other poisons. Apollodorus recommends that, in cases of poisoning, it should be boiled with a frog, and other authorities, in water only. It is a hardy plant, having much the appearance of a shrub, with prickly leaves and a jointed stem; it grows a cubit or more in height. Sometimes it is found of a whitish colour, and sometimes black, the root of it being odoriferous. It is cultivated in gardens, but it is frequently to be found growing spontaneously in rugged and craggy localities. It grows, too, on the sea-shore, in which case it is tougher and darker than usual, the leaf resembling that of parsley.

[Detailed table of contents](#)

CHAP. 9. (8.)

THE ERYNGIUM, CALLED CENTUM CAPITA: THIRTY REMEDIES.

The white variety of the eryngium is known in our language as the “centum capita.” It has all the properties above-mentioned, and the Greeks employ both the stalk and the root as an article of food, either boiled or raw. There are some marvellous facts related in connexion with this plant; the root of it, it is said, bears a strong resemblance to the organs of either sex; it is but rarely found, but if a root resembling the male organs should happen to fall in the way of a man, it will ensure him woman’s love; hence it is that Phaon the Lesbian was so passionately beloved by Sappho. Upon this subject, too, there have been numerous other reveries, not only on the part of the Magi, but of Pythagorean philosophers even as well.

So far as its medicinal properties are concerned, in addition to those already mentioned, this plant, taken in hydromel, is good for flatulency, gripings of the bowels, diseases of the heart, stomach, liver, and thoracic organs, and, taken in oxycrate, for affections of the spleen. Mixed with hydromel, it is recommended also for diseases of the kidneys, strangury, opisthotony, spasms, lumbago, dropsy, epilepsy, suppression or excess of the catamenia, and all maladies of the uterus. Applied with honey, it extracts foreign substances from the body, and, with salted axle-grease and cerate, it disperses scrofulous sores, imposthumes of the parotid glands, inflamed tumours, denudations of the bones, and fractures. Taken before drinking, it prevents the fumes of wine from rising to the head, and it arrests looseness of the bowels. Some of our authors have recommended that this plant should be gathered at the period of the summer solstice, and that it should be applied, in combination with rain water, for all kinds of maladies of the neck. They say too, that, attached as an amulet to the person, it is a cure for albugo.

Detailed table of contents

CHAP. 10. (9.)

THE ACANOS; ONE REMEDY.

There are some authors, too, who make the acanos to be a species of eryngium. It is a thorny plant, stunted, and spreading, with prickles of a considerable size. Applied topically, they say, it arrests hæmorrhage in a most remarkable degree.

Detailed table of contents

CHAP. 11.

THE GLYCYRRHIZA OR ADIPSOS: FIFTEEN REMEDIES.

Other authors, again, have erroneously taken the glycyrrhiza to be a kind of eryngium: it will, therefore, be as well to take this opportunity of making some further mention of it. There can be no doubt, however, that this is one of the thorny plants, the leaves of it being covered with prickles, substantial, and viscous and gummy to the touch: it has much the appearance of a shrub, is a couple of cubits in height, and bears a flower like that of the hyacinth, and a fruit the size of the little round balls of the plane. The best kind is that grown in Cilicia, and the next best that of Pontus the root of it is sweet, and this is the only part that is used. It is gathered at the setting of the Vergiliæ, the root of it being long, like that of the vine. That which is yellow, the colour of boxwood in fact, is superior to the darker kind, and the flexible is better than the brittle. Boiled down to one-third, it is employed for pessaries; but, for general purposes, a decoction is made of it of the consistency of honey. Sometimes, also, it is used pounded, and it is in this form that it is applied as a liniment for wounds and all affections of the throat. The juice of it is also very good for the voice, for which purpose it is thickened and then placed beneath the tongue: it is good, too, for the chest and liver.

We have already stated that this plant has the effect of allaying hunger and thirst: hence it is that some authors have given it the name of “adipsos,” and have prescribed it for dropsical patients, to allay thirst. It is for this reason, too, that it is chewed as a stomatic, and that the powder of it is often sprinkled on ulcerous sores of the mouth and films on the eyes: it heals, too, excrescences of the bladder, pains in the kidneys, condylomata, and ulcerous sores of the genitals. Some persons have given it in potions for quartan fevers, the doses being two drachmæ, mixed with pepper in one hemina of water. Chewed, and applied to wounds, it arrests hæmorrhage: some authors have asserted, also, that it expels calculi of the bladder.

[Detailed table of contents](#)

CHAP. 12. (10.)

TWO VARIETIES OF THE TRIBULUS; TWELVE REMEDIES.

Of the two kinds of tribulus, the one is a garden plant, the other grows in rivers only. There is a juice extracted from them which is employed for diseases of the eyes, it being of a cool and refreshing nature, and, consequently, useful for inflammations and abscesses. Used with honey, this juice is curative of spontaneous ulcerations, those of the mouth in particular; it is good also for affections of the tonsils. Taken in a potion, it breaks calculi of the bladder.

The Thracians who dwell on the banks of the river Strymon feed their horses on the leaves of the tribulus, and employ the kernels as an article of food, making of them a very agreeable kind of bread, which acts astringently upon the bowels. The root, if gathered by persons in a state of chastity and purity, disperses scrofulous sores; and the seed, used as an amulet, allays the pains attendant upon varicose veins: pounded and mixed with water, it destroys fleas.

[Detailed table of contents](#)

CHAP. 13. (11.)

THE STŒBE OR PHEOS.

The stœbe, by some persons known as the “pheos,” boiled in wine, is particularly good for the cure of suppurations of the ears, and for extravasations of blood in the eyes from the effects of a blow. It is employed also in injections for hæmorrhage and dysentery.

Detailed table of contents

CHAP. 14. (12.)

TWO VARIETIES OF THE HIPPOPHAES: TWO REMEDIES.

The hippophaes grows in sandy soils, and on the sea-shore. It is a plant with white thorns, and covered with clusters, like the ivy, the berries being white, and partly red. The root of it is full of a juice which is either used by itself, or else is made up into lozenges with meal of fitches: taken in doses of one obolus, it carries off bile, and it is extremely beneficial if used with honied wine. There is another hippophaes, without either stalk or flowers, and consisting only of diminutive leaves: the juice of this also is wonderfully useful for dropsy.

These plants would appear, too, to be remarkably well adopted to the constitution of the horse, as it can be for no other reason than this that they have received their name. For, in fact, there are certain plants which have been created as remedies for the diseases of animals, the Divinity being bounteously lavish of his succours and resources: so much so, indeed, that we cannot sufficiently admire the wisdom with which he has arranged them according to the classes of animated beings which they are to serve, the causes which give rise to their various maladies, and the times at which they are likely to be in requisition: hence it is that there is no class of beings, no season, and, so to speak, no day, that is without its remedy.

Detailed table of contents

CHAP. 15. (13.)

THE NETTLE: SIXTY-ONE REMEDIES.

What plant can there possibly be that is more an object of our aversion than the nettle? And yet, in addition to the oil which we have already mentioned as being extracted from it in Egypt, it abounds in medicinal properties. The seed of it, according to Nicander, is an antidote to the poison of hemlock, of fungi, and of quicksilver. Apollodorus prescribes it, too, taken in the broth of a boiled tortoise, for the bite of the salamander, and as an antidote for the poison of henbane, serpents, and scorpions. The stinging pungency even of the nettle has its uses; for, by its contact, it braces the uvula, and effects the cure of prolapsus of the uterus, and of procidence of the anus in infants. By touching the legs of persons in a lethargy, and the forehead more particularly, with nettles, they are awakened. Applied with salt, the nettle is used to heal the bites of dogs, and beaten up and applied topically, it arrests bleeding at the nostrils, the root in particular. Mixed with salt, also, it is employed for the cure of cancers and foul ulcers; and, applied in a similar manner, it cures sprains and inflamed tumours, as well as imposthumes of the parotid glands and denudations of the bones. The seed of it, taken with boiled must, dispels hysterical suffocations, and, applied topically, it arrests mucous discharges of the nostrils. Taken with hydromel, after dinner, in doses of two oboli, the seed produces a gentle vomit; and a dose of one obolus, taken in wine, has the effect of dispelling lassitude. The seed is prescribed also, parched, and in doses of one acetabulum, for affections of the uterus; and, taken in boiled must, it is a remedy for flatulency of the stomach. Taken in an electuary, with honey, it gives relief in hardness of breathing, and clears the chest by expectoration: applied with linseed, it is a cure for pains in the side, with the addition of some hyssop and a little pepper. The seed is employed also in the form of a liniment for affections of the spleen, and, parched and taken with the food, it acts as a laxative in constipation of the bowels. Hippocrates says that the seed, taken in drink, acts as a purgative upon the uterus; and that taken, parched, with sweet wine, in doses of one acetabulum, or applied externally with juice of mallows, it alleviates pains in that organ. He states also that, used with hydromel and salt, it expels intestinal worms, and that a liniment made of the seed will restore the hair when falling off. Many persons, too, employ the seed topically, with old oil, for diseases of the joints, and for gout, or else the leaves beaten up with bears'-grease: the root, too, pounded in vinegar, is no less useful for the same purposes, as also for affections of the spleen. Boiled in wine, and applied with stale axle-grease and salt, the root disperses inflamed tumours, and, dried, it is used as a depilatory.

Phanias, the physician, has enlarged upon the praises of the nettle, and he assures us that, taken with the food, either boiled or preserved, it is extremely

beneficial for affections of the trachea, cough, fluxes of the bowels, stomachic complaints, inflamed tumours, imposthumes of the parotid glands, and chilblains; that, taken with oil, it acts as a sudorific; and that, boiled with shell-fish, it relaxes the bowels. He says, too, that taken with a ptisan, it facilitates expectoration and acts as an emmenagogue, and that, applied with salt, it prevents ulcers from spreading. The juice of the nettle is also used: applied to the forehead, it arrests bleeding at the nose, taken in drink it acts as a diuretic and breaks calculi in the bladder, and, used as a gargle, it braces the uvula when relaxed.

Nettle-seed should be gathered at harvest-time: that of Alexandria is the most highly esteemed. For all these different purposes the milder and more tender plants are the best, the wild nettle in particular: this last, taken in wine, has the additional property of removing leprous spots on the face. When animals refuse to couple, it is recommended to rub the sexual organs with nettles.

[Detailed table of contents](#)

CHAP. 16. (14.)

THE LAMIUM: SEVEN REMEDIES.

The variety of nettle, too, which we have already spoken of under the name of “lamium,” the most innoxious of them all, the leaves not having the property of stinging, is used for the cure of bruises and contusions, with a sprinkling of salt, as also for burns and scrofulous sores, tumours, gout, and wounds. The middle of the leaf is white, and is used for the cure of erysipelas. Some of our authors have distinguished the various species of this plant according to their respective seasons; thus, for instance, the root of the autumn nettle, they say, carried on the person as an amulet, is a cure for tertian fevers, if due care is taken, when pulling up the root, to mention the patient’s name, and to state who he is and who are his parents. They say, too, that this plant is productive of similar results in quartan fever: and they pretend that the root of the nettle, with the addition of salt, will extract foreign substances from the body; and that the leaves, mixed with stale axle-grease, will disperse scrofulous sores, or if they suppurate, cauterize them and cause them to fill up with new flesh.

[Detailed table of contents](#)

CHAP. 17. (15.)

THE SCORPIO, TWO KINDS OF IT: ONE REMEDY.

The scorpio has received its appellation from the animal of that name, in consequence of the resemblance of its seeds to a scorpion's tail. The leaves of it are few in number, and it is efficacious for the sting of the animal from which it derives its name. There is also another plant known by the same name, and possessed of similar properties; it is destitute of leaves, has a stem like that of asparagus, and a sharp point at the top, to which it owes its appellation.

[Detailed table of contents](#)

CHAP. 18. (16.)

THE LEUCACANTHA, PHYLLOS, ISCHIAS, OR POLYGONATOS: FOUR REMEDIES.

The leucacantha, known also as the phyllos, ischias, or polygonatos, has a root like that of the cypirus, which, when chewed, has the effect of curing tooth-ache; as also pains in the sides and loins, according to Hicesius, the seed or juice being taken in drink, in doses of eight drachmæ. — This plant is employed also for the cure of ruptures and convulsions.

Detailed table of contents

CHAP. 19. (17).

THE HELXINE: TWELVE REMEDIES.

The helxine is called by some, “perdicium,” from the circumstance of its forming the principal food of partridges. Other persons, however, give it the name of “sideritis,” and to some it is known as “parthenium.” It has leaves, the shape of which is a mixture of those of the plantago and the marrubium; the stalks are slight and closely packed, and are of a light red colour. The seeds, enclosed in heads resembling those of the lappa, adhere to the clothes, a circumstance, it is said, to which it owes its name of “helxine.” We have already stated in the preceding Book what are the characteristics of the plant properly so called.

The one of which we are now speaking is used for dyeing wool, and is employed for the cure of erysipelas, tumours, all kinds of abscesses, and burns. The juice of it, taken in doses of one cyathus with white lead, is a cure for inflamed tumours, incipient swellings of the throat, and inveterate coughs. It is good, too, for all maladies of the humid parts of the body, the tonsillary glands, for instance; and, in combination with rose oil, it is useful for varicose veins. It is employed topically for the gout, with goat suet and Cyprian wax.

Detailed table of contents

CHAP. 20.

THE PERDICUM, PARTHENIUM, URCEOLARIS, OR ASTERCUM: ELEVEN REMEDIES.

The perdicium or parthenium — for the sideritis is, in reality, a different plant — is known to the people of our country as the herb urceolaris, and to some persons as the “astercum.” The leaf of it is similar to that of ocimum, but darker, and it is found growing on tiled roofs and walls. Beaten up with a sprinkling of salt, it has all the medicinal properties of the lamium, and is used in a similar manner. The juice of it, taken warm, is good, too, for suppurated abscesses; but for the cure of convulsions, ruptures, bruises, and the effects of falls from a height, or of the overturning of vehicles, it is possessed of singular virtues.

A slave, who was held in high esteem by Pericles, the ruler of the Athenians, being engaged upon the buildings of a temple in the citadel, while creeping along the top of the roof, happened to fall; from the effects of which he was relieved, it is said, by this plant, the virtues whereof had been disclosed to Pericles by Minerva in a dream. Hence it is that it was first called “parthenium,” and was consecrated to that goddess. It is this slave of whom there is a famous statue in molten bronze, well known as the Splanchnoptes.

[Detailed table of contents](#)

CHAP. 21. (18.)

THE CHASMÆLEON, IXIAS, ULOPRONON, OR CYNOZOLON; TWO VARIETIES OF IT: TWELVE REMEDIES.

The chamæleon is spoken of as the “ixias,” by some authors. There are two species of this plant; the white kind has a rougher leaf than the other, and creeps along the ground, erecting its prickles like the quills of a hedgehog; the root of it is sweet, and the odour very powerful. In some places it secretes, just as they say incense is produced, a white viscous substance beneath the axils of the leaves, about the rising of the Dog-star more particularly. To this viscous nature it owes its name of “ixias;” females make use of it as a substitute for mastich. As to its name of “chamæleon,” that is given to it from the varying tints of the leaves; for it changes its colours, in fact, just according to the soil, being black in one place, green in another, blue in a third, yellow elsewhere, and of various other colours as well.

A decoction of the root of the white chameleon is employed for the cure of dropsy, being taken in doses of one drachma in raisin wine. This decoction, taken in doses of one acetabulum, in astringent wine, with some sprigs of organum in it, has the effect of expelling intestinal worms: it is good, too, as a diuretic. Mixed with polenta, the juice of it will kill dogs and swine; with the addition of water and oil, it will attract mice to it and destroy them, unless they immediately drink water to counteract its effects. Some persons recommend the root of it to be kept, cut in small pieces, and suspended from the ceiling; when wanted, it must be boiled and taken with the food, for the cure of those fluxes to which the Greeks have given the name of “rheumatismi.”

In reference to the dark kind, some writers say that the one which bears a purple flower is the male, and that with a violet flower, the female. They grow together, upon a stem, a cubit in length, and a finger in thickness. The root of these plants, boiled with sulphur and bitumen, is employed for the cure of lichens; and they are chewed, or a decoction of them made in vinegar, to fasten loose teeth. The juice of them is employed for the cure of scab in animals, and it has the property of killing ticks upon dogs. Upon steers it takes effect like a sort of quinsy; from which circumstance it has received the name of “ulophonon” from some, as also that of cynozolon from its offensive smell. These plants produce also a viscus, which is a most excellent remedy for ulcers. The roots of all the different kinds are an antidote to the sting of the scorpion.

CHAP. 22. (19.)

THE CORONOPUS.

The coronopus is an elongated plant, with fissures in the leaves. It is sometimes cultivated, as the root, roasted in hot ashes, is found to be an excellent remedy for cœliac complaints.

Detailed table of contents

CHAP. 23. (20.)

THE ANCHUSA: FOURTEEN REMEDIES.

The root of the anchusa, too, is made use of, a plant a finger in thickness. It is split into leaves like the papyrus, and when touched it stains the hands the colour of blood; it is used for imparting rich colours to wool. Applied with cerate it heals ulcerous sores, those of aged people in particular: it is employed also for the cure of burns. It is insoluble in water, but dissolves in oil, this being, in fact, the test of its genuineness. It is administered also, in doses of one drachma, in wine, for nephretic pains, or else, if there is fever, in a decoction of balanus; it is employed in a similar manner, also, for affections of the liver and spleen, and for enlarged secretions of the bile. Applied with vinegar, it is used for the cure of leprosy and the removal of freckles. The leaves, beaten up with honey and meal, are applied topically for sprains; and taken in honied wine, in doses of two drachmæ, they arrest looseness of the bowels. A decoction of the root in water, it is said, kills fleas.

[Detailed table of contents](#)

CHAP. 24.

THE PSEUDOANCHUSA, ECHIS, OR DORIS: THREE REMEDIES.

There is another plant, similar to the preceding one, and hence known as the “pseudoanchusa,” though by some it is called “echis,” or “doris,” as well as by many other names. It is more downy than the other plant, however, and not so substantial; the leaves, too, are thinner, and more drooping. The root of it, treated with oil, does not give out any red juice, a sign by which it is distinguished from the genuine anchusa. The leaves of this plant, or the seed, taken in drink, are extremely efficacious for the stings of serpents; the leaves, too, are applied topically to the wound; and the powerful smell of them will keep serpents at a distance. A preparation of this plant is taken, also, as a potion, for affections of the vertebræ. The Magi recommend that the leaves of it should be plucked with the left hand, it being mentioned at the same time for whom they are being gathered: after which, they are to be worn as an amulet, attached to the person, for the cure of tertian fevers.

Detailed table of contents

CHAP. 25. (21.)

THE ONOCHILON, ARCHEBION, ONOCHELIS, RHEXIA, OR ENCHRYSA: THIRTY
REMEDIES.

There is another plant, too, the proper name of which is “onochilon,” but which some people call “anchusa,” others “archebion,” and others, again, “onochelis,” or “rhexia,” and, more universally, “enchrysa.” This plant has a diminutive stem, a purple flower, rough leaves and branches, and a root the colour of blood at harvest-time, though dark and swarthy at other times. It grows in sandy soils, and is extremely efficacious for the stings of serpents, vipers in particular, the roots or leaves of it being taken indifferently with the food, or in the drink. It develops its virtues at harvest-time. more especially: the leaves of it, when bruised, have just the smell of a cucumber. This plant is prescribed, in doses of three cyathi, for prolapsus of the uterus, and, taken with hyssop, it expels tape-worms. For pains in the liver or kidneys, it is taken in hydromel, if the patient shows symptoms of fever, but if not, in wine. With the root of it a liniment is made, for the removal of freckles and leprous sores; and it is asserted that persons who carry this root about them will never be attacked by serpents.

There is another plant, again, very similar to this, with a red flower, and somewhat smaller. It is applied to the same uses as the other; it is asserted, too, that if it is chewed, and then spit out upon a serpent, it will cause its instantaneous death.

Detailed table of contents

CHAP. 26.

THE ANTHEMIS, LEUCANTHEMIS, LEUCANTHEMUM, CHAMÆXMELUM, OR
MELANTHIUM; THREE VARIETIES OF IT: ELEVEN REMEDIES.

The anthemis has been highly extolled by Asclepiades. Some persons call it “leucanthemis,” some leucanthemum, others, again, “eranthemis,” from its flowering in spring, and others “chamæmelon,” because it has a smell like that of an apple: sometimes, too, it is called “melanthion.” There are three varieties of this plant, which only differ from one another in the flower; they do not exceed a palm in height, and they bear small blossoms like those of rue, white, yellow, or purple.

This plant is mostly found in thin, poor soils, or growing near foot-paths. It is usually gathered in spring, and put by for the purpose of making chaplets. At the same season, too, medical men pound the leaves, and make them up into lozenges, the same being done with the flowers also, and the root. All the parts of this plant are administered together, in doses of one drachma, for the stings of serpents of all kinds. Taken in drink, too, they bring away the dead fœtus, act as an emmenagogue and diuretic, and disperse calculi of the bladder. The anthemis is employed, also, for the cure of flatulency, affections of the liver, excessive secretions of the bile, and fistulas of the eye; chewed, it heals running sores. Of all the different varieties, the one that is most efficacious for the treatment of calculi is that with the purple flower, the leaves and stem of which are somewhat larger than those of the other kinds. Some persons, and with strict propriety, give to this last the name of “eranthemis.”

Detailed table of contents

CHAP. 27.

THE LOTUS PLANT: FOUR REMEDIES.

Those who think that the lotus is nothing but a tree only, can easily be refuted, if upon the authority of Homer only; for that poet names the lotus first of all among the herbs which grow to administer to the pleasures of the gods. The leaves of this plant, mixed with honey, disperse the marks of sores, argema, and films upon the eyes.

[Detailed table of contents](#)

CHAP. 28.

THE LOTOMETRA: TWO REMEDIES.

The lotometra is a cultivated lotus; with the seed of it, which resembles millet, the shepherds in Egypt make a coarse bread, which they mostly knead with water or milk. It is said, however, that there is nothing lighter or more wholesome than this bread, so long as it is eaten warm; but that when it gets cold, it becomes heavy and more difficult of digestion. It is a well-known fact, that persons who use it as a diet are never attacked by dysentery, tenesmus, or other affections of the bowels; hence it is, that this plant is reckoned among the remedies for that class of diseases.

[Detailed table of contents](#)

CHAP. 29.

THE HELIOTROPIUM, HELIOSCOPIUM, OR VERRUCARIA: TWELVE REMEDIES.
THE HELIOTROPIUM, TRICOCCUM, OR SCORPIURON: FOURTEEN REMEDIES.

We have spoken more than once of the marvels of the heliotropium, which turns with the sun, in cloudy weather even, so great is its sympathy with that luminary. At night, as though in regret, it closes its blue flower.

There are two species of heliotropium, the tricoccum and the helioscopium, the latter being the taller of the two, though they neither of them exceed half a foot in height. The helioscopium throws out branches from the root, and the seed of it, enclosed in follicules, is gathered at harvest-time. It grows nowhere but in a rich soil, a highly-cultivated one more particularly; the tricoccum, on the other hand, is to be found growing everywhere. I find it stated, that the helioscopium, boiled, is considered an agreeable food, and that taken in milk, it is gently laxative to the bowels; while, again, a decoction of it, taken as a potion, acts as a most effectual purgative. The juice of this plant is collected in summer, at the sixth hour of the day; it is usually mixed with wine, which makes it keep all the better. Combined with rose-oil, it alleviates head-ache. The juice extracted from the leaves, combined with salt, removes warts; from which circumstance our people have given this plant the name of “verrucaria,” although, from its various properties, it fully merits a better name. For, taken in wine or hydromel, it is an antidote to the venom of serpents and scorpions, as Apollonophanes and Apollodorus state. The leaves, too, employed topically, are a cure for the cerebral affections of infants, known as “siriasis,” as also for convulsions, even when they are epileptic. It is very wholesome, too, to gargle the mouth with a decoction of this plant. Taken in drink, it expels tapeworm and gravel, and, with the addition of cummin, it will disperse calculi. A decoction of the plant with the root, mixed with the leaves and some suet of a he-goat, is applied topically for the cure of gout.

The other kind, which we have spoken of as being called the “tricoccum,” and which also bears the name of “scorpiuron,” has leaves that are not only smaller than those of the other kind, but droop downwards towards the ground: the seed of it resembles a scorpion’s tail, to which, in fact, it owes its latter appellation. It is of great efficacy for injuries received from all kinds of venomous insects and the spider known as the “phalangium,” but more particularly for the stings of scorpions, if applied topically. Those who carry it about their person are never stung by a scorpion, and it is said that if a circle is traced on the ground around a scorpion with a sprig of this plant, the animal will never move out of it, and that if a scorpion is covered with it, or even sprinkled with tile water in which it has been steeped, it will die that instant. Four grains of the seed, taken in drink, are said to be a cure for the quartan fever, and three for the tertian; a similar effect being produced by carrying the plant three times round the patient, and then laying it under his head. The

seed, too, acts as an aphrodisiac, and, applied with honey, it disperses inflamed tumours. This kind of heliotropium, as well as the other, extracts warts radically, and excrescences of the anus. Applied topically, the seed draws off corrupt blood from the vertebre and loins; and a similar effect is produced by taking a decoction of it in chicken broth, or with beet and lentils. The husks of the seed restore the natural colour to lividities of the skin. According to the Magi, the patient himself should make four knots in the heliotropium for a quartan, and three for a tertian fever, at the same time offering a prayer that he may recover to untie them, the plant being left in the ground meanwhile.

Detailed table of contents

CHAP. 30.

THE ADIANTUM, CALLITRICHOS, TRICHOMANES, POLYTRICHOS, OR SAXIFRAGUM; TWO VARIETIES OF IT: TWENTY-EIGHT REMEDIES.

Equally marvellous, too, in other respects, is the adiantum; it is green in summer, never dies in the winter, manifests an aversion to water, and, when sprinkled with water or dipped in it, has all the appearance of having been dried, so great is its antipathy to moisture; a circumstance to which it owes the name of “*adiantum*,” given to it by the Greeks. In other respects, it is a shrub which might be well employed in ornamental gardening. Some persons give it the name of “*callitrichos*,” and others of “*polytrichos*,” both of them bearing reference to its property of imparting colour to the hair. For this purpose, a decoction of it is made in wine with parsley-seed, large quantities of oil being added, if it is desired to make the hair thick and curly as well: it has also the property of preventing the hair from coming off.

There are two kinds of this plant, one being whiter than the other, which last is swarthy and more stunted. It is the larger kind that is known as the “*polytrichos*,” or, as some call it, the “*trichomanes*.” Both plants have tiny branches of a bright black colour, and leaves like those of fern, the lower ones being rough and tawny, and all of them lying close together and attached to footstalks arranged on either side of the stem: of root, so to say, there is nothing. This plant frequents umbrageous rocks, walls sprinkled with the spray of running water, grottoes of fountains more particularly, and crags surrounded with streamlets, a fact that is all the more remarkable in a plant which derives no benefit from water.

The adiantum is of singular efficacy in expelling and breaking calculi of the bladder, the dark kind in particular; and it is for this reason, in my opinion, rather than because it grows upon stones, that it has received from the people of our country its name of “*saxifragum*.” It is taken in wine, the usual dose being a pinch of it in three fingers. Both these plants are diuretics, and act as an antidote to the venom of serpents and spiders: a decoction of them in wine arrests looseness of the bowels. A wreath of them, worn on the head, alleviates head-ache. For the bite of the scolopendra they are applied topically, but they must be removed every now and then, to prevent them from cauterizing the flesh: they are employed in a similar manner also for alopecia. They disperse scrofulous sores, scurf on the face, and running ulcers of the head. A decoction of them is useful also for asthma, affections of the liver and spleen, enlarged secretions of the gall, and dropsy. In combination with wormwood, they form a liniment for strangury and affections of the kidneys; they have the effect also of bringing away the after-birth, and act as an emmenagogue. Taken with vinegar or juice of brambleberries, they arrest hæmorrhage. Combined with rose-oil they are employed as a liniment for excoriations on infants, the parts affected being first fomented with wine. The

leaves, steeped in the urine of a youth who has not arrived at puberty, and beaten up with saltpetre, compose a liniment which, it is said, prevents wrinkles from forming on the abdomen in females. It is a general belief that partridges and cocks are rendered more pugnacious if this plant is mixed with their food; and it is looked upon as particularly beneficial for cattle.

Detailed table of contents

CHAP. 31. (22.)

THE PICRIS; ONE REMEDY. THE THESION; ONE REMEDY.

The picris derives its name from its intense bitterness, as we have previously stated. The leaf of it is round; it is remarkably efficacious for the removal of warts.

The thesium, too, has a bitterness not unlike it: it is a powerful purgative, for which purpose it is employed bruised in water.

Detailed table of contents

CHAP. 32.

THE ASPHODEL; FIFTY-ONE REMEDIES.

The asphodel is one of the most celebrated of all the plants, so much so, indeed, that by some persons it has been called "heroum." Hesiod has mentioned the fact of its growing in rivers, and Dionysius distinguishes it into male and female. It has been observed that the bulbs of it, boiled with a ptisan, are remarkably good for consumption and phthisis, and that bread in which they have been kneaded up with the meal, is extremely wholesome. Nicander recommends also, for the stings of serpents and scorpions, either the stalk, which we have already spoken of under the name of "anthericus," or else the seed or bulbs, to be taken in wine, in doses of three drachmæ; and he says that these should be strewed beneath the bed, if there is any apprehension of their presence. The asphodel is prescribed also for wounds inflicted by marine animals of a venomous nature, and the bite of the land scolopendra. It is quite wonderful how the snails, in Campania, seek the stalk of this plant, and dry it by extracting the inside. The leaves, too, are applied with wine to wounds made by venomous animals, and the bulbs are beaten up with polenta and similarly used for affections of the sinews and joints. It is also a very good plan to rub lichens with them chopped up and mixed with vinegar, and to apply them in water to putrid sores, as also to inflammations of the tests or mamillæ. Boiled in lees of wine, and applied in a linen pledged, they are used for the cure of defluxions of the eyes.

Whatever the malady may happen to be, it is generally in a boiled state that the bulbs are employed; but for foul ulcers of the legs and for chaps upon any part of the body, they are dried and reduced to powder. The bulbs are usually gathered in autumn, a period when their medicinal properties are most fully developed. The juice extracted from them pounded, or else a decoction of them, is good, mixed with honey, for pains in the body: it is employed also with dried iris and a little salt by those who wish to impart an agreeable odour to the person. The leaves are used for the cure of the various maladies above mentioned, as also, boiled in wine, for scrofulous sores, inflamed tumours, and ulcers of the face. The ashes of the root are a remedy for alopecia and chaps on the feet; and an extract of the root, boiled in oil, is good for burns and chilblains. It is injected also into the ears for deafness, and, for tooth-ache, it is poured into the ear opposite to the part affected. A moderate dose of the root, taken in drink, acts as a diuretic and emmenagogue; it is good also for pains in the sides, ruptures, convulsions, and coughs, in doses of one drachma, taken in wine. Chewed, the root promotes vomiting, but the seed, taken internally, disorders the bowels.

Chrysermus used to employ a decoction of the root, in wine, for imposthumes of the parotid glands; and he has prescribed it, in combination

with cachrys, in wine, for the cure of scrofulous sores. Some persons say that if, after applying the root to the sores, a part of it is hung up in the smoke to dry, and not taken down till the end of four days, the sores will gradually dry up with this portion of the root. Sophocles used to employ it both ways, boiled and raw, for the cure of gout; and he prescribes it, boiled in oil, for chilblains, and, in vinegar, for jaundice and dropsy. It has been stated, also, that, used as a friction with wine and honey, or taken in drink, it acts as an aphrodisiac. Xenocrates assures us, too, that a decoction of the root in vinegar removes lichens, itchscabs, and leprous sores; and that a decoction of it, with henbane and tar, has a similar effect, and is good also for the removal of bad odours of the armpits and thighs: he states, also, that if the head is well rubbed with the root, being first shaved, the hair will curl all the better for it. Simus prescribes a decoction of it, in wine, to be taken for calculi in the kidneys; and Hippocrates recommends the seed for obstructions of the spleen. The root, or else a decoction of it, applied topically, restores the hair in beasts of burden, where it has been lost by ulcerations or scab. It has the effect, too, of driving away rats and mice, and of exterminating them, if placed before their holes.

Detailed table of contents

CHAP. 33.

THE HALIMON: FOURTEEN REMEDIES.

Some authors have thought that it is the asphodel that is called “halimon” by Hesiod, an opinion which appears to me ill-founded; halimon being the name of a distinct plant, which has been the occasion of no few mistakes committed by writers. According to some, it is a tufted shrub, white, destitute of thorns, and with leaves like those of the olive, only softer; which eaten boiled, are an agreeable food. The root, they say, taken in doses of one drachma in hydromel, allays gripings of the bowels, and is a cure for ruptures and convulsions. Others, again, pronounce it to be a vegetable growing near the sea-shore, of a salt taste — to which, in fact, it owes its name — with leaves somewhat round but elongated, and much esteemed as an article of food. They say, too, that there are two species of it, the wild and the cultivated, and that, mixed with bread, they are good, both of them, for dysentery, even if ulceration should have supervened, and are useful for stomachic affections, in combination with vinegar. They state, also, that this plant is applied raw to ulcers of long standing, and that it modifies the inflammation of recent wounds, and the pain attendant upon sprains of the feet and affections of the bladder. The wild halimon, they tell us, has thinner leaves than the other, but is more effectual as a medicament in all the above cases, as also for the cure of itch, whether in man or beast. The root, too, according to them, employed as a friction, renders the skin more clear, and the teeth whiter; and they assert that if the seed of it is put beneath the tongue, no thirst will be experienced. They state, also, that this kind is eaten as well as the other, and that they are, both of them, preserved.

Crateuas has spoken of a third kind also, with longer leaves than the others, and more hairy: it has the smell of the cypress, he says, and grows beneath the ivy more particularly. He states that this plant is extremely good for opisthotony and contractions of the sinews, taken in doses of three oboli to one sextarius of water.

[Detailed table of contents](#)

CHAP. 34.

THE ACANTHUS, PÆDEROS, OR MELAMPHYLLOS: FIVE REMEDIES.

The acanthus is a plant that grows in cities, and is used in ornamental gardening. It has a broad, long leaf, and is used as a covering for the margins of ornamental waters and of parterres in gardens. There are two varieties of it; the one that is thorny and crisped is the shorter of the two; the other, which is smooth, is by some persons called “pæderos,” and by others “melamphyllos.” The root of this last is remarkably good for burns and sprains; and, boiled with the food, a ptisan more particularly, it is equally good for ruptures, spasms, and patients who are in apprehension of phthisis. The root is also beaten up and applied warm for hot gout.

Detailed table of contents

CHAP. 35.

THE BUPLEURON: FIVE REMEDIES.

The bupleuron is reckoned by the Greeks in the number of the leguminous plants which grow spontaneously. The stem of it is a cubit in height, the leaves are long and numerous, and the head resembles that of dill. It has been extolled as an aliment by Hippocrates, and for its medicinal properties by Glaucon and Nicander. The seed of it is good for the stings of serpents; and the leaves, or else the juice, applied as a liniment with wine, bring away the after-birth. The leaves, also, in combination with salt and wine, are applied to scrofulous sores. The root is prescribed in wine for the stings of serpents, and as a diuretic.

[Detailed table of contents](#)

CHAP. 36.

THE BUPRESTIS: ONE REMEDY.

With a remarkable degree of inconsistency, the Greek writers, while praising the buprestis as an aliment, point out certain antidotes to it, as though it were a poison. The very name, however, proves to a certainty that it is poisonous to cattle, and it is generally admitted that, on tasting it, they burst asunder: we shall, therefore, say no more about it. Is there any reason, in fact, why, when we are speaking of the materials employed in making our grass crowns, we should de- scribe a poison? or really ought we to enlarge upon it only to please the libidinous fancies of those who imagine that there is not a more powerful aphrodisiac in existence than this, when taken in drink?

Detailed table of contents

CHAP. 37.

THE ELAPHOBOSCON: NINE REMEDIES.

The elaphoboscon is a ferulaceous plant, articulated, and about a finger in thickness. The seed of it is like that of dill, hanging in umbels resembling those of hart-wort in appearance, but not bitter. The leaves are very like those of olusatrum. This plant, too, is highly spoken of as an article of food; in addition to which, it is preserved and kept as a diuretic and for the purpose of assuaging pains in the sides, curing ruptures and convulsions, and dispelling flatulency and colic. It is used, too, for the cure of wounds inflicted by serpents and all kinds of animals that sting; so much so, indeed, that, as the story goes, stags, by eating of it, fortify themselves against the attacks of serpents. The root, too, applied topically, with the addition of nitre, is a cure for fistula, but, when wanted for this purpose, it must be dried first, so as to retain none of the juice; though, on the other hand, this juice does not at all impair its efficacy as an antidote to the poison of serpents.

Detailed table of contents

CHAP. 38.

THE SCANDIX: NINE REMEDIES. THE ANTHRISCUM: TWO REMEDIES.

The scandix, too, is reckoned by the Greeks in the number of the wild vegetables, as we learn from Opion and Erasistratus. Boiled, it arrests looseness of the bowels; and the seed of it, administered with vinegar, immediately stops hiccup. It is employed topically for burns, and acts as a diuretic; a decoction of it is good, too, for affections of the stomach, liver, kidneys, and bladder. It is this plant that furnished Aristophanes with his joke against the poet Euripides, that his mother used to sell not real vegetables, but only scandix.

The anthriscum would be exactly the same plant as the scandix, if its leaves were somewhat thinner and more odoriferous. Its principal virtue is that it reinvigorates the body when exhausted by sexual excesses, and acts as a stimulant upon the enfeebled powers of old age. It arrests leucorrhœa in females.

Detailed table of contents

CHAP. 39.

THE IASIONE; FOUR REMEDIES.

The iasione, which is also looked upon as a wild vegetable, is a creeping plant, full of a milky juice: it bears a white flower, the name given to which is “concilium.” The chief recommendation of this plant, too, is that it acts as an aphrodisiac. Eaten with the food, raw, in vinegar, it promotes the secretion of the milk in nursing women. It is salutary also for patients who are apprehensive of phthisis; and, applied to the head of infants, it makes the hair grow, and renders the scalp more firm.

Detailed table of contents

CHAP. 40.

THE CAUCALIS: TWELVE REMEDIES.

The caucalis, too, is an edible plant. It resembles fennel in appearance, and has a short stem with a white flower; it is usually considered a good cordial. The juice, too, of this plant is taken as a potion, being particularly recommended as a stomachic, a diuretic, an expellent of calculi and gravel, and for the cure of irritations of the bladder. It has the effect, also, of attenuating morbid secretions of the spleen, liver, and kidneys. The seed of it acts as an emmenagogue, and dispels the bilious secretions after child-birth: it is prescribed also, for males, in cases of seminal weakness. Chrysippus is of opinion that this plant promotes conception; for which purpose it is taken by women in wine, fasting. It is employed in the form of a liniment, for wounds inflicted by marine animals of a venomous nature, at least we find it so stated by Petrichus in his poem.

[Detailed table of contents](#)

CHAP. 41.

THE SIUM: ELEVEN REMEDIES.

Among these plants there is reckoned also the sium: it grows in the water, has a leaf broader than that of parsley, thicker, and of a more swarthy colour, bears a considerable quantity of seed, and has the taste of nasturtium. It is an active diuretic, is very good for the kidneys and spleen, and acts as an emmenagogue, either eaten by itself as an aliment, or taken in the form of a decoction; the seed of it is taken in wine, in doses of two drachmæ. It disperses calculi in the bladder, and neutralizes the action of water which tends to their formation. Used in the form of an injection, it is good for dysentery, and applied topically, for the removal of freckles. It is applied by females, at night, for the removal of spots on the face, a result which it produces almost instantaneously. It has the effect also of assuaging hernia, and is good for the scab in horses.

[Detailed table of contents](#)

CHAP. 42.

THE SILLYBUM.

The sillybum resembles the white chamæleon, and is a plant quite as prickly. In Cilicia, Syria, and Phoenicia, the countries where it grows, it is not thought worth while to boil it, the cooking of it being so extremely troublesome, it is said. It is of no use whatever in medicine.

Detailed table of contents

CHAP. 43.

THE SCOLYMOS OR LIMONIA: FIVE REMEDIES.

The scolymos, too, is used as an aliment in the East, where it has also the name of “limonia.” This is a shrub-like plant, which never exceeds a cubit in height, with tufted leaves and a black root, but sweet. Eratosthenes speaks highly of it as a diet used by the poor. It is said to possess diuretic properties in a very high degree, and to heal lichens and leprous sores, applied with vinegar. Taken in wine it acts as an aphrodisiac, according to the testimony of Hesiod and Alcæus; who have stated in their writings, that while it is in blossom, the song of the grasshopper is louder than at other times, women more inflamed with desire, and men less inclined to amorous intercourse; and that it is by a kind of foresight on the part of Nature that this powerful stimulant is then in its greatest perfection. The root, too, used without the pith, corrects the noisome odour of the armpits, in doses of one ounce to two heminæ of Falernian wine; the mixture being boiled down to one third, and taken fasting after the bath, as also after meals, a cyathus at a time. It is a remarkable thing, but Xenocrates assures us that he has ascertained it experimentally, that these bad odours are carried off by the urine.

Detailed table of contents

CHAP. 44.

THE SONCHOS; TWO VARIETIES: FIFTEEN REMEDIES.

The sonchos, too, is edible — at least, it was this that, according to Callimachus, Hecale set before Theseus. There are two kinds, the white and the black: they are, both of them, similar to the lettuce, except that they are prickly, with a stem a cubit in height, angular, and hollow within; when broken, the stem gives out an abundance of milky juice. The white kind, which derives its colour from the milk it contains, is good for hardness of breathing, if eaten dressed with seasoning like the lettuce. Erasistratus says that it carries off calculi by the urine, and that, chewed, it is a corrective of bad breath. The juice of it, taken warm in doses of three cyathi, with white wine and oil, facilitates delivery, but the patient must be careful to walk about immediately after drinking it: it is also given in broth.

A decoction of the stalk renders the milk more abundant in nursing women, and improves the complexion of the infants suckled by them; it is also remarkably beneficial for females when the milk coagulates. The juice of it is used as an injection for the ears, and is taken warm in doses of one cyathus, for strangury, as also for gnawing pains of the stomach, with cucumber seed and pine nuts. It is employed topically for abscesses of the rectum, and is taken in drink for the stings of serpents and scorpions, the root also being applied to the wounds. The root, boiled in oil, with the rind of a pomegranate, is a remedy for diseases of the ears — all these remedies, however, be it remembered, are derived from the white kind.

As to the black sonchos, Cleemporus forbids it to be eaten, as being productive of diseases, but at the same time he approves of the use of the white. Agathocles, however, goes so far as to assert that the juice of the black kind is an antidote for poisoning by bulls' blood; and, indeed, it is generally agreed that the black sonchos has certain refreshing properties; for which reason cataplasms of it may be advantageously applied with polenta. Zeno recommends the root of the white kind for strangury.

[Detailed table of contents](#)

CHAP. 45.

THE CONDRION OR CHONDRYLLA: SIX REMEDIES.

The condrion, or chondrylla, has leaves, eaten away, as it were, at the edges, and similar to those of endive, a stalk less than a foot in length and full of a bitter juice, and a root resembling that of the bean, and occasionally very ramified. It produces, near the surface of the earth, a sort of mastich, in a tubercular form, the size of a bean; this mastich, it is said, employed as a pessary, promotes the menstrual discharge. This plant, pounded whole with the roots, is divided into lozenges, which are employed for the stings of serpents, and probably with good effect; for field mice, it is said, when injured by those reptiles, are in the habit of eating this plant. A decoction of it in wine arrests looseness of the bowels, and makes a most excellent substitute for gum, as a bandoline for the eye-lashes, even when the hairs are most stubborn. Dorotheus says, in his poems, that it is extremely good for the stomach and the digestive organs. Some persons, however, have been of opinion that it is unwholesome for females, bad for the eyesight, and productive of impotence in the male sex.

[Detailed table of contents](#)

CHAP. 46.

MUSHROOMS: PECULIARITIES OF THEIR GROWTH.

Among those vegetable productions which are eaten with risk, I shall, with good reason, include mushrooms; a very dainty food, it is true, but deservedly held in disesteem since the notorious crime committed by Agrippina, who, through their agency, poisoned her husband, the Emperor Claudius, and at the same moment, in the person of his son Nero, inflicted another poisonous curse upon the whole world, herself in particular.

Some of the poisonous mushrooms are easily known, being of a rank, unwholesome look, light red without and livid within, with the clefts considerably enlarged, and a pale, sickly margin to the head. These characteristics, however, are not presented by others of the poisonous kinds; but being dry to all appearance and strongly resembling the genuine ones, they present white spots upon the head, on the surface of the outer coat. The earth, in fact, first produces the uterus or receptacle for the mushroom, and then the mushroom within, like the yolk in the egg. Nor is this envelope less conducive to the nutrition of the young mushroom [than is the albumen of the egg to that of the chicken.] Bursting forth from the envelope at the moment of its first appearance, as it gradually increases it becomes transformed into a substantial stalk; it is but very rarely, too, that we find two growing from a single foot-stalk. The generative principle of the mushroom is in the slime and the fermenting juices of the damp earth, or of the roots of most of the glandiferous trees. It appears at first in the shape of a sort of viscous foam, and then assumes a more substantial but membranous form, after which, as already stated, the young mushroom appears.

In general, these plants are of a pernicious nature, and the use of them should be altogether rejected; for if by chance they should happen to grow near a hob-nail, a piece of rusty iron, or a bit of rotten cloth, they will immediately imbibe all these foreign emanations and flavours, and transform them into poison. Who, in fact, is able to distinguish them, except those who dwell in the country, or the persons that are in the habit of gathering them? There are other circumstances, too, which render them noxious; if they grow near the hole of a serpent, for instance, or if they should happen to have been breathed upon by one when just beginning to open; being all the more disposed to imbibe the venom from their natural affinity to poisonous substances.

It will therefore be as well to be on our guard during the season at which the serpents have not as yet retired to their holes for the winter. The best sign to know this by is a multitude of herbs, of trees, and of shrubs, which remain green from the time that these reptiles leave their holes till their return; indeed, the ash alone will be quite sufficient for the purpose, the leaves of it

never coming out after the serpents have made their appearance, or beginning to fall before they have retired to their holes. The entire existence of the mush- room, from its birth to its death, is never more than seven days.

CHAP. 47. (23.)

FUNGI; SIGNS BY WHICH THE VENOMOUS KINDS MAY BE RECOGNIZED: NINE
REMEDIES.

Fungi are of a more humid nature than the last, and are divided into numerous kinds, all of which are derived solely from the pituitous humours of trees. The safest are those, the flesh of which is red, the colour being more pronounced than that of the mushroom. The next best are the white ones, the stems of which have a head very similar to the apex worn by the Flamens; and a third kind are the suilli, very conveniently adapted for poisoning. Indeed, it is but very recently that they have carried off whole families, and all the guests at a banquet; Linnæus Serenus, for instance, the prefect of Nero's guard, together with all the tribunes and centurions. What great pleasure, then, can there be in partaking of a dish of so doubtful a character as this? Some persons have classified these fungi according to the trees to which they are indebted for their formation, the fig, for instance, the fennel-giant, and the gummiferous trees; those belonging to the beech, the robur, and the cypress, not being edible, as already mentioned. But who is there to give us a guarantee when they come to market, that these distinctions have been observed?

All the poisonous fungi are of a livid colour; and the degree of similarity borne by the sap of the tree itself to that of the fig will afford an additional indication whether they are venomous or not. We have already mentioned various remedies for the poison of fungi, and shall have occasion to make mention of others; but in the mean time, it will be as well to observe that they themselves also have some medicinal uses. Glaucias is of opinion that mushrooms are good for the stomach. The suilli are dried and strung upon a rush, as we see done with those brought from Bithynia. They are employed as a remedy for the fluxes known as "rheumatismi," and for excrescences of the fundament, which they diminish and gradually consume. They are used, also, for freckles and spots on women's faces. A wash, too, is made of them, as is done with lead, for maladies of the eyes. Steeped in water, they are applied topically to foul ulcers, eruptions of the head, and bites inflicted by dogs.

I would here also give some general directions for the cooking of mushrooms, as this is the only article of food that the voluptuaries of the present day are in the habit of dressing with their own hands, and so feeding upon it in anticipation, being provided with amber-handled knives and silver plates and dishes for the purpose. Those fungi may be looked upon as bad which become hard in cooking; while those, on the other hand, are comparatively innoxious, which admit of being thoroughly boiled, with the addition of some nitre. They will be all the safer if they are boiled with some meat or the stalks of pears: it is a very good plan, too, to eat pears directly after them. Vinegar, too, being of a nature diametrically opposed to them, neutralizes their dangerous qualities.

Detailed table of contents

CHAP. 48.

SULPHUR: SEVEN REMEDIES.

All these productions owe their origin to rain, and by rain is silphium produced. It originally came from Cyrenæ, as already stated: at the present day, it is mostly imported from Syria, the produce of which country, though better than that of Media, is inferior to the Parthian kind. As already observed, the silphium of Cyrenæ no longer exists. It is of considerable use in medicine, the leaves of it being employed to purge the uterus, and as an expellent of the dead fœtus; for which purposes a decoction of them is made in white aromatic wine, and taken in doses of one acetabulum, immediately after the bath. The root of it is good for irritations of the trachea, and is employed topically for extravasated blood; but, used as an aliment, it is difficult of digestion, being productive of flatulency and eructations: it is injurious, also, to the urinary secretions. Combined with wine and oil, it is extremely good for bruises, and, with wax, for the cure of scrofulous sores. Repeated fumigations with the root cause excrescences of the anus to subside.

[Detailed table of contents](#)

CHAP. 49.

LASER: THIRTY-NINE REMEDIES.

Laser, a juice which distils from silphium, as we have already stated, and reckoned among the most precious gifts presented to us by Nature, is made use of in numerous medicinal preparations. Employed by itself, it warms and revives persons benumbed with cold, and, taken in drink, it alleviates affections of the sinews. It is given to females in wine, and is used with soft wool as a pessary to promote the menstrual discharge. Mixed with wax, it extracts corns on the feet, after they have been first loosened with the knife: a piece of it, the size of a chick-pea, melted in water, acts as a diuretic. Andreas assures us that, taken in considerable doses even, it is never productive of flatulency, and that it greatly promotes the digestion, both in aged people and females; he says, too, that it is better used in winter than in summer, and that even then, it is best suited for those whose beverage is water: but due care must be taken that there is no internal ulceration. Taken with the food, it is very refreshing for patients just recovering from an illness; indeed, if it is used at the proper time, it has all the virtues of a desiccatory, though it is more wholesome for persons who are in the habit of using it than for those who do not ordinarily employ it.

As to external maladies, the undoubted virtues of this medicament are universally acknowledged: taken in drink, it has the effect, also, of neutralizing the venom of serpents and of poisoned weapons, and, applied with water, it is in general use for the cure of wounds. In combination with oil, it is only used as a liniment for the stings of scorpions, and with barley-meal or dried figs, for the cure of ulcers that have not come to a head. It is applied topically, also, to carbuncles, with rue or honey, or else by itself, with some viscous substance to make it adhere; for the bites of dogs, also, it is similarly employed. A decoction of it in vinegar, with pomegranate rind, is used for excrescences of the fundament, and, mixed with nitre, for the corns commonly known as "morticini." In cases of alopecy which have been first treated with nitre, it makes the hair grow again, applied with wine and saffron, or else pepper or mouse-dung and vinegar. For chilblains, fomentations are made of it with wine, or liniments with oil; as also for callosities and indurations. For corns on the feet, if pared first, it is particularly useful, as also as a preservative against the effects of bad water, and of unhealthy climates or weather. It is prescribed for cough, too, affections of the uvula, jaundice of long standing, dropsy, and hoarseness, having the effect of instantly clearing the throat and restoring the voice. Diluted in oxycrate, and applied with a sponge, it assuages the pains in gout.

It is given also in broth to patients suffering from pleurisy, when about to take wine; and it is prescribed for convulsions and opisthotony, in pills about

as large as a chick-pea coated with wax. For quinsy, it is used as a gargle, and to patients troubled with asthma or inveterate cough, it is given with leeks in vinegar; it is prescribed, also, with vinegar, after drinking butter-milk. It is recommended with wine for consumptive affections of the viscera and epilepsy, and with hy-dromel for paralysis of the tongue; with a decoction of honey, it forms a liniment for sciatica and lumbago.

For my own part, I should not recommend, what some authors advise, to insert a pill of laser, covered with wax, in a hollow tooth, for tooth-ache; being warned to the contrary by a remarkable case of a man, who, after doing so, threw himself headlong from the top of a house. Besides, it is a well-known fact, that if it is rubbed on the muzzle of a bull, it irritates him to an extraordinary degree; and that if it is mixed with wine, it will cause serpents to burst — those reptiles being extremely fond of wine. In addition to this, I should not advise any one to rub the gums with Attic honey, although that practice is recommended by some.

It would be an endless task to enumerate all the uses to which laser is put, in combination with other substances; and the more so, as it is only our object to treat of simple remedies, it being these in which Nature displays her resources. In the compound remedies, too, we often find our judgment deceived, and quite at fault, from our comparative inattention to the sympathy or antipathy which naturally exists between the ingredients employed — on this subject, however, we shall have to enlarge on a future occasion.

Detailed table of contents

CHAP. 50. (24.)

PROPOLIS: FIVE REMEDIES.

Honey would be held in no less esteem than laser, were it not for the fact that nearly every country produces it. Laser is the production of Nature herself; but, for the formation of honey, she has created an insect, as already described. The uses to which honey is put are quite innumerable, if we only consider the vast number of compositions in which it forms an ingredient. First of all, there is the propolis, which we find in the hives, as already mentioned. This substance has the property of extracting stings and all foreign bodies from the flesh, dispersing tumours, ripening indurations, allaying pains of the sinews, and cicatrizing ulcers of the most obstinate nature.

As to honey itself, it is of so peculiar a nature, that it prevents putrefaction from supervening, by reason of its sweetness solely, and not any inherent acidity, its natural properties being altogether different from those of salt. It is employed with the greatest success for affections of the throat and tonsils, for quinsy and all ailments of the mouth, as also in fever, when the tongue is parched. Decoctions of it are used also for peripneumony and pleurisy, for wounds inflicted by serpents, and for the poison of fungi. For paralysis, it is prescribed in honied wine, though that liquor also has its own peculiar virtues. Honey is used with rose-oil, as an injection for the ears; it has the effect also of exterminating nits and foul vermin of the head. It is the best plan always to skim it before using it.

Still, however, honey has a tendency to inflate the stomach; it increases the bilious secretions also, produces qualmishness, and, according to some, if employed by itself, is injurious to the sight: though, on the other hand, there are persons who recommend ulcerations at the corners of the eyes to be touched with honey.

As to the elementary principles of honey, the different varieties of it, the countries where it is found, and its characteristic features, we have enlarged upon them on previous occasions: first, when treating of the nature of bees, and secondly, when speaking of that of flowers; the plan of this work compelling us to separate subjects which ought properly to be united, if we would arrive at a thorough knowledge of the operations of Nature.

[Detailed table of contents](#)

CHAP. 51.

THE VARIOUS INFLUENCES OF DIFFERENT ALIMENTS UPON THE DISPOSITION.

While speaking of the uses of honey, we ought also to treat of the properties of hydromel. There are two kinds of hydromel, one of which is prepared at the moment, and taken while fresh, the other being kept to ripen. The first, which is made of skimmed honey, is an extremely wholesome beverage for invalids who take nothing but a light diet, such as strained alica for instance: it reinvigors the body, is soothing to the mouth and stomach, and by its refreshing properties allays feverish heats. I find it stated, too, by some authors, that to relax the bowels it should be taken cold, and that it is particularly well-suited for persons of a chilly temperament, or of a weak and pusillanimous constitution, such as the Greeks, for instance, call “micropsychi.”

For there is a theory, remarkable for its extreme ingenuity, first established by Plato, according to which the primary atoms of bodies, as they happen to be smooth or rough, angular or round, are more or less adapted to the various temperaments of individuals: and hence it is, that the same substances are not universally sweet or bitter to all. So, when affected with lassitude or thirst, we are more prone to anger than at other times. These asperities, however, of the disposition, or rather I should say of the mind, are capable of being modified by the sweeter beverages; as they tend to lubricate the passages for the respiration, and to mollify the channels, the work of inhalation and exhalation being thereby unimpeded by any rigidities. Every person must be sensible of this experiment- ally, in his own case: there is no one in whom anger, affection, sadness, and all the emotions of the mind may not, in some degree, be modified by diet. It will therefore be worth our while to observe what aliments they are which exercise a physical effect, not only upon the body, but the disposition as well.

Detailed table of contents

CHAP. 52.

HYDROMEL: EIGHTEEN REMEDIES.

Hydromel is recommended, too, as very good for a cough: taken warm, it promotes vomiting. With the addition of oil it counteracts the poison of white lead; of henbane, also, and of the haliacabum, as already stated, if taken in milk, asses' milk in particular. It is used as an injection for diseases of the ears, and in cases of fistula of the generative organs. With crumb of bread it is applied as a poultice to the uterus, as also to tumours suddenly formed, sprains, and all affections which require soothing applications. The more recent writers have condemned the use of fermented hydromel, as being not so harmless as water, and less strengthening than wine. After it has been kept a considerable time, it becomes transformed into a wine, which, it is universally agreed, is extremely prejudicial to the stomach, and injurious to the nerves.

[Detailed table of contents](#)

CHAP. 53.

HONIED WINE: SIX REMEDIES.

As to honied wine, that is always the best which has been made with old wine: honey, too, incorporates with it very readily, which is never the case with sweet wine. When made with astringent wine, it does not clog the stomach, nor has it that effect when the honey has been boiled: in this last case, too, it causes less flatulency, an inconvenience generally incidental to this beverage. It acts as a stimulant also upon a failing appetite; taken cold it relaxes the bowels, but used warm it acts astringently, in most cases, at least. It has a tendency also to make flesh. Many persons have attained an extreme old age, by taking bread soaked in honied wine, and no other diet — the famous instance of Pollio Romilius, for example. This man was more than one hundred years old when the late Emperor Augustus, who was then his host, asked him by what means in particular he had retained such remarkable vigour of mind and body.— “Honied wine within, oil without,” was his answer. According to Varro, the jaundice has the name of “royal disease” given to it, because its cure is effected with honied wine.

[Detailed table of contents](#)

CHAP. 54.

MELITITES: THREE REMEDIES.

We have already described how melitites is prepared, of must and honey, when speaking on the subject of wines. It is, I think, some ages, however, since this kind of beverage was made, so extremely productive as it was found to be of flatulency. It used, however, to be given in fever, to relieve inveterate costiveness of the bowels, as also for gout and affections of the sinews. It was prescribed also for females who were not in the habit of taking wine.

[Detailed table of contents](#)

CHAP. 55.

WAX: EIGHT REMEDIES.

To an account of honey, that of wax is naturally appended, of the origin, qualities, and different kinds of which, we have previously made mention on the appropriate occasions. Every kind of wax is emollient and warming, and tends to the formation of new flesh; fresh wax is, however, the best. It is given in broth to persons troubled with dysentery, and the combs themselves are sometimes used in a pottage made of parched alica. Wax counteracts the bad effects of milk; and ten pills of wax, the size of a grain of millet, will prevent milk from coagulating in the stomach. For swellings in the groin, it is found beneficial to apply a plaster of white wax to the pubes.

Detailed table of contents

CHAP. 56.

REMARKS IN DISPARAGEMENT OF MEDICINAL COMPOSITIONS.

As to the different uses to which wax is applied, in combination with other substances in medicine, we could no more make an enumeration of them than we could of all the other ingredients which form part of our medicinal compositions. These preparations, as we have already observed, are the results of human invention. Cerates, poultices, plasters, eyesalves, antidotes, — none of these have been formed by Nature, that parent and divine framer of the universe; they are merely the inventions of the laboratory, or rather, to say the truth, of human avarice. The works of Nature are brought into existence complete and perfect in every respect, her ingredients being but few in number, selected as they are from a due appreciation of cause and effect, and not from mere guesswork; thus, for instance, if a dry substance is wanted to assume a liquefied form, a liquid, of course, must be employed as a vehicle, while liquids, on the other hand, must be united with a dry substance to render them consistent. But as for man, when he pretends, with balance in hand, to unite and combine the various elementary substances, he employs himself not merely upon guesswork, but proves himself guilty of downright impudence.

It is not my intention to touch upon the medicaments afforded by the drugs of India, or Arabia and other foreign climates: I have no liking for drugs that come from so great a distance; they are not produced for us, no, nor yet for the natives of those countries, or else they would not be so ready to sell them to us. Let people buy them if they please, as ingredients in perfumes, unguents, and other appliances of luxury; let them buy them as adjuncts to their superstitions even, if incense and costus we must have to propitiate the gods; but as to health, we can enjoy that blessing without their assistance, as we can easily prove — the greater reason then has luxury to blush at its excesses.

Detailed table of contents

CHAP. 57.

REMEDIES DERIVED FROM GRAIN. SILIGO: ONE REMEDY. WHEAT: ONE REMEDY. CHAFF: TWO REMEDIES. SPELT: ONE REMEDY. BRAN: ONE REMEDY. OLYRA, OR ARINCA: TWO REMEDIES.

Having now described the remedies derived from flowers, both those which enter into the composition of garlands, and the ordinary garden ones, as well as from the vegetable productions, how could we possibly omit those which are derived from the cereals?

(25.) It will be only proper then, to make some mention of these as well. In the first place, however, let us remark that it is a fact universally acknowledged, that it is the most intelligent of the animated beings that derive their subsistence from grain. The grain of siligo highly roasted and pounded in Aminean wine, applied to the eyes, heals defluxions of those organs; and the grain of wheat, parched on a plate of iron, is an instantaneous remedy for frost-bite in various parts of the body. Wheat-meal, boiled in vinegar, is good for contractions of the sinews, and bran, mixed with rose-oil, dried figs, and myxa plums boiled down together, forms an excellent gargle for the tonsillary glands and throat.

Sextus Pomponius, who had a son prætor, and who was himself the first citizen of Nearer Spain, was on one occasion attacked with gout, while superintending the winnowing in his granaries; upon which, he immediately thrust his legs, to above the knees, in a heap of wheat. He found himself relieved, the swelling in the legs subsided in a most surprising degree, and from that time he always employed this remedy: indeed, the action of grain in masses is so extremely powerful as to cause the entire evaporation of the liquor in a cask. Men of experience in these matters recommend warm chaff of wheat or barley, as an application for hernia, and fomentations with the water in which it has been boiled. In the grain known as spelt, there is a small worm found, similar in appearance to the teredo: if this is put with wax into the hollow of carious teeth, they will come out, it is said, or, indeed, if the teeth are only rubbed with it. Another name given to olyra, as already mentioned, is “arinca:” with a decoction of it a medicament is made, known in Egypt as “athera,” and extremely good for infants. For adult persons it is employed in the form of a liniment.

CHAP. 58.

THE VARIOUS KINDS OF MEAL: TWENTY-EIGHT REMEDIES.

Barley-meal, raw or boiled, disperses, softens, or ripens gatherings and inflammatory tumours; and for other purposes a decoction of it is made in hydromel, or with dried figs. If required for pains in the liver, it must be boiled with oxycrate in wine. When it is a matter of doubt whether an abscess should be made to suppurate or be dispersed, it is a better plan to boil the meal in vinegar, or lees of vinegar, or else with a decoction of quinces or pears. For the bite of the millepede, it is employed with honey, and for the stings of serpents, and to prevent suppurations, with vinegar. To promote suppuration, it should be used with oxycrate, with the addition of Gallic resin. For gatherings, also, that have come to a head, and ulcers of long standing, it must be employed in combination with resin, and for indurations, with pigeons' dung, dried figs, or ashes. For inflammation of the tendons, or of the intestines and sides, or for pains in the male organs and denudations of the bones, it is used with poppies, or melilote; and for scrofulous sores, it is used with pitch and oil, mixed with the urine of a youth who has not reached the years of puberty. It is employed also with fenugreek for tumours of the thoracic organs, and in fevers, with honey, or stale grease.

For suppurations, however, wheat-meal is much more soothing; it is applied topically also for affections of the sinews, mixed with the juice of henbane, and for the cure of freckles, with vinegar and honey. The meal of zea, from which, as already stated, an alica is made, appears to be more efficacious than that of barley even: but that of the three month kind is the most emollient. It is applied warm, in red wine, to the stings of scorpions, as also for affections of the trachea, and spitting of blood: for coughs, it is employed in combination with goat suet or butter.

The meal of fenugreek, however, is the most soothing of them all: boiled with wine and nitre, it heals running ulcers, eruptions on the body, and diseases of the feet and mamillæ. The meal of æra is more detergent than the other kinds, for inveterate ulcers and gangrenes: in combination with radishes, salt, and vinegar, it heals lichens, and with virgin sulphur, leprosy: for headache, it is applied to the forehead with goose-grease. Boiled in wine, with pigeons' dung and linseed, it ripens inflamed tumours and scrofulous sores.

[Detailed table of contents](#)

CHAP. 59.

POLENTA: EIGHT REMEDIES.

Of the various kinds of polenta we have already treated sufficiently at length, when speaking of the places where it is made. It differs from barley meal, in being parched, a process which renders it more wholesome for the stomach. It arrests looseness of the bowels, and heals inflammatory eruptions; and it is employed as a liniment for the eyes, and for head-ache, combined with mint or some other refreshing herb. It is used in a similar manner also for chilblains and wounds inflicted by serpents; and with wine, for burns. It has the effect also of checking pustular eruptions.

[Detailed table of contents](#)

CHAP. 60.

FINE FLOUR: FIVE REMEDIES. PULS: ONE REMEDY. MEAL USED FOR PASTING
PAPYRUS: ONE REMEDY.

The flour of bolted meal, kneaded into a paste, has the property of drawing out the humours of the body: hence it is applied to bruises gorged with blood, to extract the corrupt matter, even to soaking the bandages employed: used with boiled must, it is still more efficacious. It is used as an application also for callosities of the feet and corns; boiled with old oil and pitch, and applied as hot as possible, it cures condylomata and all other maladies of the fundament in a most surprising manner. Puls is a very feeding diet. The meal used for pasting the sheets of papyrus is given warm to patients for spitting of blood, and is found to be an effectual cure.

Detailed table of contents

CHAP. 61.

ALICA: SIX REMEDIES.

Alica is quite a Roman invention, and not a very ancient one: for otherwise the Greeks would never have written in such high terms of the praises of ptisan in preference. I do not think that it was yet in use in the days of Pompeius Magnus, a circumstance which will explain why hardly any mention has been made of it in the works of the school of Asclepiades. That it is a most excellent preparation no one can have a doubt, whether it is used strained in hydromel, or whether it is boiled and taken in the form of broth or puls. To arrest flux of the bowels, it is first parched and then boiled with honeycomb, as already mentioned: but it is more particularly useful when there is a tendency to phthisis after a long illness, the proper proportions being three cyathi of it to one sextarius of water. This mixture is boiled till all the water has gone off by evaporation, after which one sextarius of sheep' or goats' milk is added: it is then taken by the patient daily, and after a time some honey is added. By this kind of nutriment a deep decline may be cured.

[Detailed table of contents](#)

CHAP. 62.

MILLET: SIX REMEDIES.

Millet arrests looseness of the bowels and dispels gripings of the stomach, for which purposes it is first parched. For pains in the sinews, and of various other descriptions, it is applied hot, in a bag, to the part affected. Indeed, there is no better topical application known, as it is extremely light and emollient, and retains heat for a very long time: hence it is that it is so much employed in all those cases in which the application of heat is necessary. The meal of it, mixed with tar, is applied to wounds inflicted by serpents and millepedes.

[Detailed table of contents](#)

CHAP. 63.

PANIC: FOUR REMEDIES.

Diodes, the physician, has given to panic the name of “honey of corn.” It has the same properties as millet, and, taken in wine, it is good for dysentery. In a similar manner, too, it is applied to such parts of the body as require to be treated with heat. Boiled in goats’-milk, and taken twice a-day, it arrests looseness of the bowels; and, used in a similar manner, it is very good for gripings of the stomach.

Detailed table of contents

CHAP. 64.

SESAME: SEVEN REMEDIES. SESAMOIDES: THREE REMEDIES. ANTICYRICUM:
THREE REMEDIES.

Sesame, pounded and taken in wine, arrests vomiting: it is applied also topically to inflammations of the ears, and burns. It has a similar effect even while in the blade: and in that state, a decoction of it in wine is used as a liniment for the eyes. As an alignment it is injurious to the stomach, and imparts a bad odour to the breath. It is an antidote to the bite of the spotted lizard, and heals the cancerous sore known as “cacoethes.” The oil made from it, as already mentioned, is good for the ears.

Sesamoïdes owes its name to its resemblance to sesame; the grain of it, however, is bitter, and the leaf more diminutive: it is found growing in sandy soils. Taken in water, it carries off bile, and, with the seed, a liniment is made for erysipelas: it disperses inflamed swellings also. Besides this, there is another sesamoïdes, which grows at Anticyra, and, for that reason, is known by some as “anticyricon.” In other respects, it is similar to the plant erigeron, of which we shall have to speak on a future occasion; but the seed of it is like that of sesame. It is given in sweet wine as an evacuant, in doses of a pinch in three fingers, mixed with an obolus and a half of white hellebore; this preparation being employed principally as a purgative, in cases of insanity, melancholy, epilepsy, and gout. Taken alone, in doses of one drachma, it purges by stool.

Detailed table of contents

CHAP. 65.

BARLEY: NINE REMEDIES. MOUSE-BARLEY, BY THE GREEKS CALLED
PHŒNICE: ONE REMEDY.

The whitest barley is the best. Boiled in rain-water, the pulp of it is divided into lozenges, which are used in injections for ulcerations of the intestines and the uterus. The ashes of barley are applied to burns, to bones denuded of the flesh, to purulent eruptions, and to the bite of the shrewmouse: sprinkled with salt and honey they impart whiteness to the teeth, and sweetness to the breath. It is alleged that persons who are in the habit of eating barley-bread are never troubled with gout in the feet: they say, too, that if a person takes nine grains of barley, and traces three times round a boil, with each of them in the left hand, and then throws them all into the fire, he will experience an immediate cure. There is another plant, too, known as “phœnice” by the Greeks, and as “mouse-barley” by us: pounded and taken in wine, it acts remarkably well as an emmenagogue.

Detailed table of contents

CHAP. 66.

PTISAN: FOUR REMEDIES.

To ptisan, which is a preparation of barley, Hippocrates has devoted a whole treatise; praises, however, which at the present day are all transferred to “alica,” being, as it is, a much more wholesome preparation. Hippocrates, however, recommends it as a pottage, for the comparative ease with which, from its lubricous nature, it is swallowed; as also, because it allays thirst, never swells in the stomach, passes easily through the intestines, and is the only food that admits of being given twice a-day in fever, at least to patients who are in the habit of taking two meals — so opposed is his method to that of those physicians who are for famishing their patients. He forbids it to be given, however, without being first strained; for no part, he says, of the ptisan, except the water, should be used. He says, too, that it must never be taken while the feet are cold, and, indeed, that no drink of any kind should be taken then. With wheat a more viscous kind of ptisan is made, which is found to be still more efficacious for ulcerations of the trachea.

[Detailed table of contents](#)

CHAP. 67.

AMYLUM: EIGHT REMEDIES. OATS: ONE REMEDY.

Amylum weakens the eyesight, and is bad for the throat, whatever opinions may be held to the contrary. It has the effect also of arresting looseness of the bowels, and curing defluxions and ulcerations of the eyes, as also pustules and congestions of the blood. It mollifies indurations of the eyelids, and is given with egg to persons when they vomit blood. For pains of the bladder, half an ounce of it is prescribed with an egg, and as much raisin wine as three eggshells will hold, the mixture to be made lukewarm and taken immediately after the bath. Oatmeal, boiled in vinegar, removes moles.

[Detailed table of contents](#)

CHAP. 68.

BREAD: TWENTY-ONE REMEDIES.

Bread, too, which forms our ordinary nutriment, possesses medicinal properties, almost without number. Applied with water and oil, or else rose-oil, it softens abscesses; and, with hydromel, it is remarkably soothing for indurations. It is prescribed with wine to produce delitescence, or when a defluxion requires to be checked; or, if additional activity is required, with vinegar. It is employed also for the morbid defluxions of rheum, known to the Greeks as “rheumatismi,” and for bruises and sprains. For all these purposes, however, bread made with leaven, and known as “autopyrus,” is the best.

It is applied also to whitlows, in vinegar, and to callosities of the feet. Stale bread, or sailors’-bread, beaten up and baked again, arrests looseness of the bowels. For persons who wish to improve the voice, dry bread is very good, taken fasting; it is useful also as a preservative against catarrhs. The bread called “sitanius,” and which is made of three-month wheat, applied with honey, is a very efficient cure for contusions of the face and scaly eruptions. White bread, steeped in hot or cold water, furnishes a very light and wholesome aliment for patients. Soaked in wine, it is applied as a poultice for swellings of the eyes, and used in a similar manner, or with the addition of dried myrtle, it is good for pustules on the head. Persons troubled with palsy are recommended to take bread soaked in water, fasting, immediately after the bath. Burnt bread modifies the close smell of bedrooms, and, used in the strainers, it neutralizes bad odours in wine.

Detailed table of contents

CHAP. 69.

BEANS: SIXTEEN REMEDIES.

Beans, too, furnish us with some remedies. Parched whole, and thrown hot into strong vinegar, they are a cure for grip- ings of the bowels. Bruised, and boiled with garlic, they are taken with the daily food for inveterate coughs, and for suppurations of the chest. Chewed by a person fasting, they are applied topically to ripen boils, or to disperse them; and, boiled in wine, they are employed for swellings of the testes and diseases of the genitals. Bean-meal, boiled in vinegar, ripens tumours and breaks them, and heals contusions and burns. M. Varro assures us that beans are very good for the voice. The ashes of bean stalks and shells, with stale hogs' - lard, are good for sciatica and inveterate pains of the sinews. The husks, too, boiled down, by themselves, to one-third, arrest looseness of the bowels.

Detailed table of contents

CHAP. 70.

LENTILS: SEVENTEEN REMEDIES.

Those lentils are the best which boil the most easily, and those in particular which absorb the most water. They injure the eye-sight, no doubt, and inflate the stomach; but taken with the food, they act astringently upon the bowels, more particularly if they are thoroughly boiled in rain-water: if, on the other hand, they are lightly boiled, they are laxative. They break purulent ulcers, and they cleanse and cicatrize ulcerations of the mouth. Applied topically, they allay all kinds of abscesses, when ulcerated and chapped more particularly; with melilote or quinces they are applied to defluxions of the eyes, and with polenta they are employed topically for suppurations. A decoction of them is used for ulcerations of the mouth and genitals, and, with rose-oil or quinces, for diseases of the fundament. For affections which demand a more active remedy, they are used with pomegranate rind, and the addition of a little honey; to prevent the composition from drying too quickly, beet leaves are added. They are applied topically, also, to scrofulous sores, and to tumours, whether ripe or only coming to a head, being thoroughly-boiled first in vinegar. Mixed with hydromel they are employed for the cure of chaps, and with pomegranate rind for gangrenes. With polenta they are used for gout, for diseases of the uterus and kidneys, for chilblains, and for ulcerations which cicatrize with difficulty. For a disordered stomach, thirty grains should be eaten.

For cholera, however, and dysentery, it is the best plan to boil the lentils in three waters, in which case they should always be parched first, and then pounded as fine as possible, either by themselves, or else with quinces, pears, myrtle, wild endive, black beet, or plantago. Lentils are bad for the lungs, head-ache, all nervous affections, and bile, and are very apt to cause restlessness at night. They are useful, however, for pustules, erysipelas, and affections of the mamillæ, boiled in sea-water; and, applied with vinegar, they disperse indurations and scrofulous sores. As a stomachic, they are mixed, like polenta, with the drink given to patients. Parboiled in water, and then pounded and bolted through a sieve to disengage the bran, they are good for burns, care being taken to add a little honey as they heal: they are boiled, also, with oxycrate for diseases of the throat.

There is a marsh-lentil also, which grows spontaneously in stagnant waters. It is of a cooling nature, for which reason it is employed topically for abscesses, and for gout in particular, either by itself or with polenta. Its glutinous properties render it a good medicine for intestinal hernia.

CHAP. 71.

THE ELELISPHACOS, SPHACOS, OR SALVIA: THIRTEEN REMEDIES.

The plant called by the Greeks “elelisphacos,” or “sphacos,” is a species of wild lentil, lighter than the cultivated one, and with a leaf, smaller, drier, and more odoriferous. There is also another kind of it, of a wilder nature, and possessed of a powerful smell, the other one being milder. It has leaves the shape of a quince, but white and smaller: they are generally boiled with the branches. This plant acts as an emmenagogue and a diuretic: and it affords a remedy for wounds inflicted by the sting-ray, having the property of benumbing the part affected. It is taken in drink with wormwood for dysentery: employed with wine it accelerates the catamenia when retarded, a decoction of it having the effect of arresting them when in excess: the plant, applied by itself, stanches the blood of wounds. It is a cure, too, for the stings of serpents, and a decoction of it in wine allays prurigo of the testes.

Our herbalists of the present day take for the “elelisphacos” of the Greeks the “salvia” of the Latins, a plant similar in appearance to mint, white and aromatic. Applied externally, it expels the dead fœtus, as also worms which breed in ulcers and in the ears.

Detailed table of contents

CHAP. 72.

THE CHICKPEA AND THE CHICHELING VETCH: TWENTY-THREE REMEDIES.

There is a wild chickpea also, which resembles in its leaf the cultivated kind, and has a powerful smell. Taken in considerable quantities, it relaxes the bowels, and produces griping pains and flatulency; parched, however, it is looked upon as more wholesome. The chicheling vetch, again, acts more beneficially upon the bowels. The meal of both kinds heals running sores of the head — that of the wild sort being the more efficacious of the two — as also epilepsy, swellings of the liver, and stings inflicted by serpents. It acts as an emmenagogue and a diuretic, used in the grain more particularly, and it is a cure for lichens, inflammations of the testes, jaundice, and dropsy. All these kinds, however, exercise an injurious effect upon ulcerations of the bladder and kidneys: but in combination with honey they are very good for gangrenous sores, and the cancer known as “cacoethes.” The following is a method adopted for the cure of all kinds of warts: on the first day of the moon, each wart must be touched with a single chickpea, after which, the party must tie up the pease in a linen cloth, and throw it behind him; by adopting this plan, it is thought, the warts will be made to disappear.

Our authors recommend the plant known as the “arietinum” to be boiled in water with salt, and two cyathi of the decoction to be taken for strangury. Employed in a similar manner, it expels calculi, and cures jaundice. The water in which the leaves and stalks of this plant have been boiled, applied as a fomentation as hot as possible, allays gout in the feet, an effect equally produced by the plant itself, beaten up and applied warm. A decoction of the columbine chickpea, it is thought, moderates the shivering fits in tertian or quartan fevers; and the black kind, beaten up with half a nut-gall, and applied with raisin wine, is a cure for ulcers of the eyes.

Detailed table of contents

CHAP. 73.

THE FITCH: TWENTY REMEDIES.

In speaking of the fitch, we have mentioned certain properties belonging to it; and, indeed, the ancients have attributed to it no fewer virtues than they have to the cabbage. For the stings of serpents, it is employed with vinegar; as also for bites inflicted by crocodiles and human beings. If a person eats of it, fasting, every day, according to authors of the very highest authority, the spleen will gradually diminish. The meal of it removes spots on the face and other parts of the body. It prevents ulcers from spreading also, and is extremely efficacious for affections of the mamillæ: mixed with wine, it makes carbuncles break. Parched, and taken with a piece of honey the size of a hazel nut, it cures dysuria, flatulency, affections of the liver, tenesmus, and that state of the body in which no nourishment is derived from the food, generally known as “atrophy.” For cutaneous eruptions, plasters are made of it boiled with honey, being left to remain four days on the part affected. Applied with honey, it prevents inflamed tumours from suppurating. A decoction of it, employed as a fomentation, cures chilblains and prurigo; and it is thought by some, that if it is taken daily, fasting, it will improve the complexion of all parts of the body.

Used as an aliment, this pulse is far from wholesome, being apt to produce vomiting, disorder the bowels, and stuff the head and stomach. It weakens the knees also; but the effects of it may be modified by keeping it in soak for several days, in which case it is remarkably beneficial for oxen and beasts of burden. The pods of it, beaten up green with the stalks and leaves, before they harden, stain the hair black.

Detailed table of contents

CHAP. 74.

LUPINES: THIRTY-FIVE REMEDIES.

There are wild lupines, also, inferior in every respect to the cultivated kinds, except in their bitterness. Of all the alimentary substances, there are none which are less heavy or more useful than dried lupines. Their bitterness is considerably modified by cooking them on hot ashes, or steeping them in hot water. Employed frequently as an article of food, they impart freshness to the colour; the bitter lupine, too, is good for the sting of the asp. Dried lupines, stripped of the husk and pounded, are applied in a linen cloth to black ulcers, in which they make new flesh: boiled in vinegar, they disperse scrofulous sores and imposthumes of the parotid glands. A decoction of them, with rue and pepper, is given in fever even, as an expellent of intestinal worms, to patients under thirty years of age. For children, also, they are applied to the stomach as a vermifuge, the patient fasting in the meantime and, according to another mode of treatment, they are parched and taken in boiled must or in honey.

Lupines have the effect of stimulating the appetite, and of dispelling nausea. The meal of them, kneaded up with vinegar, and applied in the bath, removes pimples and prurigo; employed alone, it dries up ulcerous sores. It cures bruises also, and, used with polenta, allays inflammations. The wild lupine is found to be the most efficacious for debility of the hips and loins. A decoction of them, used as a fomentation, removes freckles and improves the skin; and lupines, either wild or cultivated, boiled down to the consistency of honey, are a cure for black eruptions and leprosy. An application of cultivated lupines causes carbuncles to break, and reduces inflamed tumours and scrofulous sores, or else brings them to a head: boiled in vinegar, they restore the flesh when cicatrized to its proper colour. Thoroughly boiled in rain-water, the decoction of them furnishes a deterusive medicine, of which fomentations are made for gangrenes, purulent eruptions, and runing ulcers. This decoction is very good, taken in drink, for affections of the spleen, and with honey, for retardations of the catamenia. Beaten up raw, with dried figs, lupines are applied externally to the spleen. A decoction of the root acts as a diuretic.

The herb chamæleon, also, is boiled with lupines, and the water of it strained off, to be used as a potion for cattle. Lupines boiled in amurca, or a decoction of them mixed with amurca, heals the itch in beasts. The smoke of lupines kills gnats.

CHAP. 75.

IRIO, OR ERYSIMUM, BY THE GAULS CALLED VELA: FIFTEEN REMEDIES.

When treating of the cereals, we have already stated that the irio, which strongly resembles sesame, is also called “erysimon “ by the Greeks: the Gauls give it the name of “vela.” It is a branchy plant, with leaves like those of rocket, but a little narrower, and a seed similar to that of nasturtium. With honey, it is extremely good for cough and purulent expectorations: it is given, also, for jaundice and affections of the loins, pleurisy, gripings of the bowels, and cœliac affections, and is used in liniments for imposthumes of the parotid glands and carcinomatous affections. Employed with water, or with honey, it is useful for inflammations of the testes, and is extremely beneficial for the diseases of infants. Mixed with honey and figs, it is good for affections of the fundament and diseases of the joints; and taken in dink, it is an excellent antidote to poisons. It is used, also, for asthma, and with stale axle- grease for fistulas; but it must not be allowed to touch the interior of them.

Detailed table of contents

CHAP. 76.

HORMINUM: SIX REMEDIES.

Horminum resembles cummin, as already stated, in its seed; but in other respects, it is like the leek. It grows to some nine inches in height, and there are two varieties of it. In one of these the seed is oblong, and darker than that of the other, and the plant itself is in request as an aphrodisiac, and for the cure of argema and albugo in the eyes: of the other kind the seed is whiter, and of a rounder form. Both kinds, pounded and applied with water, are used for the extraction of thorns from the body. The leaves, steeped in vinegar, disperse tumours, either used by themselves, or in combination with honey; they are employed, also, to disperse boils, before they have come to a head, and other collections of acrid humours.

Detailed table of contents

CHAP. 77.

DARNEL: FIVE REMEDIES.

Even more than this — the very plants which are the bane of the corn-field are not without their medicinal uses. Darnel has received from Virgil the epithet of “unhappy;” and yet, ground and boiled with vinegar, it is used as an application for the cure of impetigo, which is the more speedily effected the oftener the application is renewed. It is employed, also, with oxymel, for the cure of gout and other painful diseases. The following is the mode of treatment: for one sextarius of vinegar, two ounces of honey is the right proportion; three sextarii having been thus prepared, two sextarii of darnel meal are boiled down in it to a proper consistency, the mixture being applied warm to the part affected. This meal, too, is used for the extraction of splinters of broken bones.

[Detailed table of contents](#)

CHAP. 78.

THE PLANT MILIARIA: ONE REMEDY.

“Miliaria” is the name given to a plant which kills millet: this plant, it is said, is a cure for gout in beasts of burden, beaten up and administered in wine, with the aid of a horn.

[Detailed table of contents](#)

CHAP. 79.

BROMOS: ONE REMEDY.

Bromos is the seed also of a plant which bears an ear. It is a kind of oat which grows among corn, to which it is injurious; the leaves and stalk of it resemble those of wheat, and at the extremity it bears seeds, hanging down, something like small locusts in appearance. The seed of this plant is useful for plasters, like barley and other grain of a similar nature. A decoction of it is good for coughs.

[Detailed table of contents](#)

CHAP. 80.

OROBANCHE, OR CYNOMORION: ONE REMEDY.

We have mentioned orobanche as the name of a plant which kills the fitch and other leguminous plants. Some persons have called it “cynomorion,” from the resemblance which it bears to the genitals of a dog. The stem of it is leafless, thick, and red. It is eaten either raw, or boiled in the saucepan, while young and tender.

Detailed table of contents

CHAP. 81.

REMEDIES FOR INJURIES INFLICTED BY INSECTS WHICH BREED AMONG LEGUMINOUS PLANTS.

There are some venomous insects also, of the solipuga kind, which breed upon leguminous plants, and which, by stinging the hands, endanger life. For these stings all those remedies are efficacious which have been mentioned for the bite of the spider and the phalangium. Such, then, are the medicinal properties for which the cereals are employed.

Detailed table of contents

CHAP. 82.

THE USE MADE OF THE YEAST OF ZYTHUM.

Different beverages, too, are made from the cereals, zythum in Egypt, cælia and cerea in Spain, cervesia and numerous liquors in Gaul and other provinces. The yeast of all of these is used by women as a cosmetic for the face. — But as we are now speaking of beverages, it will be the best plan to pass on to the various uses of wine, and to make a beginning with the vine of our account of the medicinal properties of the trees.

Summary. — Remedies, narratives, and observations, nine hundred and six.

Authors quoted. — All those mentioned in the preceding Book: and, in addition to them, Chrysermus, Eratosthenes, and Alcæus.

Detailed table of contents

BOOK XXIII. THE REMEDIES DERIVED FROM THE CULTIVATED TREES.

Detailed table of contents

CHAP. 1. (1.)

INTRODUCTION.

We have now set forth the various properties, medicinal or otherwise, as well of the cereals as of the other productions which lie upon the surface of the earth, for the purpose either of serving us for food, or for the gratification of our senses with their flowers or perfumes. In the trees, however, Pomona has entered the lists with them, and has imparted certain medicinal properties to the fruits as they hang. Not content with protecting and nourishing, under the shadow of the trees, the various plants which we have already described, she would even appear to be indignant, as it were, at the thought that we should derive more succour from those productions which are further removed from the canopy of heaven, and which have only come into use in times comparatively recent. For she bids man bear in mind that it was the fruits of the trees which formed his first nourishment, and that it was these which first led him to look upwards towards the heavens: and not only this, but she reminds him, too, that even still it is quite possible for him to derive his aliment from the trees, without being indebted to grain for his subsistence.

Detailed table of contents

CHAP. 2.

THE VINE.

But, by Hercules! it is the vine more particularly to which she has accorded these medicinal properties, as though she were not contented with her generosity in providing it with such delicious flavours, and perfumes, and essences, in its omphacium, its œnanthe, and its massaris, preparations upon which we have already enlarged. “It is to me,” she says, “that man is indebted for the greater part of his enjoyments, it is I that produce for him the flowing wine and the trickling oil, it is I that ripen the date and other fruits in numbers so varied; and all this, not insisting, like the earth, on their purchase at the cost of fatigues and labours. No necessity do I create for ploughing with the aid of oxen, for beating out upon the threshing-floor, or for bruising under the millstone, and all in order that man may earn his food at some indefinite time by this vast expenditure of toil. As for me, all my gifts are presented to him ready prepared: for no anxieties or fatigues do they call, but, on the contrary, they offer themselves spontaneously, and even fall to the ground, if man should be too indolent to reach them as they hang.” Vying even with herself, Pomona has done still more for our practical advantage than for the mere gratification of our pleasures and caprices.

Detailed table of contents

CHAP. 3.

THE LEAVES AND SHOOTS OF THE VINE: SEVEN REMEDIES.

The leaves and shoots of the vine, employed with polenta, allay head-ache and reduce inflammations: the leaves, too, applied by themselves with cold water, are good for burning pains in the stomach; and, used with barley-meal, are excellent applications for diseases of the joints. The shoots, beaten up and applied, have the property of drying up all kinds of running tumours, and the juice extracted from them is used as an injection for the cure of dysentery. The tears of the vine, which would appear to be a sort of gum, will heal leprossores, lichens, and itch-scabs, if treated first with nitre: used with oil, and applied frequently to superfluous hairs, they act as a depilatory, those more particularly which exude from the vine when burnt in a green state: this last liquid has the effect, too, of removing warts. An infusion of the shoots in water, taken in drink, is good for persons troubled with spitting of blood, and for the fainting fits which sometimes ensue upon conception.

The bark of the vine and the dried leaves arrest the flowing of blood from wounds, and make the sores cicatrize more rapidly. The juice of the white vine, extracted from it while green, effectually removes cutaneous eruptions. The ashes of the cuttings of vines, and of the husks of the grapes, applied with vinegar, are curative of condylomata and diseases of the fundament; as also of sprains, burns, and swellings of the spleen, applied with rose-oil, rue, and vinegar. Used with wine, but without oil, they make a fomentation for erysipelas and parts of the body which are chafed; they act as a depilatory also. For affections of the spleen the ashes of vine-cuttings, moistened with vinegar, are administered in drink, being taken in doses of two cyathi in warm water; after which the patient must take due care to lie upon the side in which the spleen is situate.

The tendrils, too, which the vine throws out as it climbs, beaten up in water and drunk, have the effect of arresting habitual vomiting. The ashes of the vine, used with stale axle-grease, are good for tumours, act as a detergent upon fistulas, and speedily effect a radical cure; the same, too, with pains and contractions of the sinews, occasioned by cold. Applied with oil, they are useful for contusions, and with vinegar and nitre, for fleshy excrescences upon the bones: in combination with oil, they are good, too, for wounds inflicted by scorpions and dogs. The ashes of the bark, employed by themselves, restore the hair to such parts of the body as have suffered from the action of fire.

CHAP. 4.

OMPHACIUM EXTRACTED FROM THE VINE: FOURTEEN REMEDIES.

We have already mentioned, when speaking of the composition of unguents, how omphacium is made from the grape, when it is just beginning to form: we shall now proceed to speak of its medicinal properties. Omphacium heals ulcerations of the humid parts of the body, such as the mouth, tonsillary glands, and generative organs, for example; it is very good, too, for the sight, for rough spots upon the eyelids, ulcers at the corners of the eyes, films upon the eyes, running sores on all parts of the body, cicatrizations slow in forming, and purulent discharges from the ears. The powerful action of omphacium is modified by the admixture of honey or raisin wine. It is very useful, too, for dysentery, spitting of blood, and quinsy.

Detailed table of contents

CHAP. 5.

CENANTHE: TWENTY-ONE REMEDIES.

Next to omphacium comes cenanthe, a product of the wild vine, described by us already when treating of the unguents. The most esteemed kind is that of Syria, the produce of the white vine in the vicinity of the mountains of Antiochia and Laodicea in particular. Being of a cooling, astringent nature, it is used for sprinkling upon sores, and is employed as a topical application for diseases of the stomach. It acts also as a diuretic, and is good for maladies of the liver, head-ache, dysentery, cœliac affections, and attacks of cholera: for nausea, it is taken in doses of one obolus in vinegar. It acts as a desiccative upon running eruptions of the head, and is extremely efficacious for maladies of the humid parts of the body; hence it is that it is employed, with honey and saffron, for ulcers of the mouth, and for diseases of the generative organs and the fundament. It arrests looseness of the bowels, and heals eruptions of the eyelids and runnings at the eyes: taken with wine, it cures derangements of the stomach, and with cold water, spitting of blood.

The ashes of cenanthe are highly esteemed as an ingredient in eye-salves, and as a detergent for ulcers, whitlows, and hang-nails; to obtain these ashes, it is put into an oven, and left there till the bread is thoroughly baked.

As to massaris, it is used as a perfume only. The renown attached to all these preparations is due solely to the innate greediness of mankind, which has racked its invention to gather the productions of the earth before they have arrived at maturity.

Detailed table of contents

CHAP. 6.

GRAPES, FRESH GATHERED.

As to grapes when allowed to gain maturity, the black ones have more marked properties than the others; and hence it is, that the wine made from them is not so agreeable. The white grapes, on the other hand, are sweeter, for, being transparent, the air penetrates them with greater facility.

Grapes fresh gathered are productive of flatulency, and disturb the stomach and bowels; hence it is that they are avoided in fevers, in large quantities more particularly. Indeed, they are very apt to produce oppression of the head, and to bring on the malady known as lethargy. Grapes which have been gathered, and left to hang for some time, are much less injurious, the exposure to the air rendering them beneficial even to the stomach, and refreshing to the patient, as they are slightly cooling, and tend to remove nausea and qualmsiness.

Detailed table of contents

CHAP. 7.

VARIOUS KINDS OF PRESERVED GRAPES: ELEVEN REMEDIES.

Grapes which have been preserved in wine or in must are trying to the head. Next to the grapes which have been left to hang in the air, are those which have been kept in chaff; but as to those which have been preserved among grape husks, they are injurious to the head, the bladder, and the stomach, though at the same time they arrest looseness of the bowels, and are extremely good for patients troubled with spitting of blood. When preserved in must, they are worse even in their effects than when kept among husks; boiled must, too, renders them injurious to the stomach. It is the opinion of medical writers, that grapes kept in rain-water are the most wholesome of all, even though they are by no means agreeable eating; for the benefit of them is particularly experienced in burning pains of the stomach, biliousness arising from a disordered liver, vomiting of bile, and attacks of cholera, as also dropsy and burning fevers.

Grapes kept in earthen pots sharpen the taste, the stomach, and the appetite; it is thought, however, that they are rendered a little heavy by the exhalations from the husks with which they are covered. If vine-blossoms are given to poultry, mixed with their food, they will never touch the grapes.

[Detailed table of contents](#)

CHAP. 8.

CUTTINGS OF THE VINE: ONE REMEDY.

Such cuttings of the vine as have borne grapes, have an astringent effect, when they are preserved in earthen pots, more particularly.

Detailed table of contents

CHAP. 9.

GRAPE-STONES: SIX REMEDIES.

Grape-stones, also, have a similar property; it is through them that wine is so apt to produce head-ache. Parched and then pounded, they are beneficial for the stomach; and this powder is sprinkled, like polenta, in the beverage of patients suffering from dysentery, cœliac affections, and derangements of the stomach. A decoction of them is useful, also, as a fomentation for itch-scabs and prurigo.

Detailed table of contents

CHAP. 10.

GRAPE-HUSKS: EIGHT REMEDIES.

Grape-husks, used by themselves, are less injurious to the head and bladder than grape-stones are: beaten up with salt, they form an excellent liniment for inflammations of the *ma- millæ*. A decoction of them, taken in drink, or employed as a fomentation, is good for inveterate dysentery, and *cœliac* affections.

Detailed table of contents

CHAP. 11.

THE GRAPES OF THE THERIACA: FOUR REMEDIES.

The grape of the theriaca, of which we have already made mention on the appropriate occasion, is eaten by way of antidote to the stings of serpents. It is recommended, too, to eat the young shoots of this tree, and to apply them topically. The wine and vinegar made from these grapes are productive of a similar salutary effect.

[Detailed table of contents](#)

CHAP. 12.

RAISINS, OR ASTAPHIS: FOURTEEN REMEDIES.

Raisins, the name given to which is “astaphis,” would be injurious to the stomach, abdomen, and intestines, were it not for the stones within them, which act as a corrective. When the stones are removed, raisins, it is thought, are beneficial to the bladder, and good for cough: in the last case, the raisin of the white grape is considered the best. Raisins are good also for the trachea and the kidneys, and the wine made from them is particularly efficacious for the sting of the serpent called hæmorrhōis. In combination with meal of cummin or coriander, they are employed topically for inflammations of the testes. For carbuncles and diseases of the joints, the stones are removed, and the raisins are pounded with rue; if used for ulcers, the sores must be first fomented with wine.

Used with the stones, raisins are a cure for epinyctis, honeycomb ulcers, and dysentery; and for gangrenes they are applied topically with radish rind and honey, being first boiled in oil. They are used with panax, for gout and loose nails; and they are sometimes eaten by themselves, in combination with pep- per, for the purpose of cleansing the mouth and clearing the brain.

Detailed table of contents

CHAP. 13

THE ASTAPHISAGRIA, OTHERWISE CALLED STAPHIS OR TAMINIA: TWELVE REMEDIES.

The wild astaphis, otherwise called staphis, is by some persons erroneously called “uva taminia;” for it is altogether a distinct plant from the other. It has a black, upright stem, with leaves resembling those of the labrusca, and bears what we may call a pod, rather than a grape, green, similar to a chick-pea in appearance, and enclosing a kernel of triangular form. The fruit of it ripens with the vintage and turns black, while the berries of the taminia, as is well known, are red; this last, too, as we are aware, grows only in shaded spots, while the wild astaphis, on the other hand, loves a site that is exposed to the sun.

I would not recommend any one to use the kernels of the wild astaphis as a purgative, as it is very doubtful whether they might not choke the patient; nor would I advise them to be employed for the purpose of attenuating the phlegm, as they are extremely irritating to the throat. Beaten up, however, and applied topically, they kill vermin in the head and other parts of the body, more particularly if they are used with sandarach; they are very useful, too, for itch-scabs and prurigo. A decoction of the kernels is made with vinegar, for the cure of tooth-ache, diseases of the ears, cicatrices that are slow in healing, and running sores.

The blossoms of the plant are beaten up and taken in wine for stings inflicted by serpents; but, as to the seed, I would strongly recommend its rejection, on account of its extremely pungent properties. Some persons give to this plant the name of “pituitaria,” and use it as a common application for stings inflicted by serpents.

Detailed table of contents

CHAP. 14.

THE LABRUSCA, OR WILD VINE: TWELVE REMEDIES.

The labrusca, too, produces an œnanthe, which has been described at sufficient length already: by the Greeks the labrusca is known as the wild vine. The leaves of it are thick and of a whitish colour, the stem is jointed, and the bark full of fissures: it bears grapes of a scarlet hue, like the coccus, which are made use of by females for the purpose of improving the complexion, and removing spots upon the face. Pounded with the leaves and the juice extracted from the tree, these grapes are usefully employed for the treatment of lumbago and sciatica. A decoction of the root in water, taken in two cyathi of Coan wine, promotes an alvine evacuation of aqueous secretions; for which reason it is prescribed for dropsy.

I am inclined to think that; this is the plant that is commonly known as the “uva taminia;” it is in great request as an amulet, and is employed, though as a gargle only, in cases of spitting blood; for which purpose, salt, thyme, and oxymel are added to it, care being taken not to swallow any of the mixture. It is generally looked upon as unsafe to employ it as a purgative.

Detailed table of contents

CHAP. 15.

THE SALICASTRUM: TWELVE REMEDIES.

There is another plant, similar to the labrusca, but found growing in willow-beds; for which reason it is known by a distinct name, though the uses to which it is applied are just the same. The name given to it is “salicastrum;” beaten up with oxymel, it displays marvellous efficacy in the removal of itch-scab and prurigo in men and cattle.

CHAP. 16.

THE WHITE VINE, OTHERWISE CALLED AMPELOLEUCE, STAPHYLE, MELOTHRON, PSILOTRUM, ARCHEZOSTIS, CEDROSTIS, OR MADON: THIRTY-ONE REMEDIES.

The white vine is known to the Greeks by the various names of ampeloleuce, staphyle, melothron, psilotrum, archezostis, cedrostis, and madon. The twigs of this tree are jointed, thin, and climbing, with considerable interstices between the knots. The leaves, attached to the numerous shoots, and about the size of an ivy leaf, are jagged at the edges, like that of the vine. The root of it is large and white, and very like a radish at first; from it issue several stems, Similar to asparagus in appearance. These stems, eaten boiled, are both purgative and diuretic. The leaves, too, as well as the stems, are possessed of caustic properties; for which reason they are employed topically with salt, for phagedænic sores, gangrenes, and putrid ulcers of the legs. The fruit of the tree is in the form of grapes thinly scattered, the juice of which is red at first, and afterwards of a saffron colour. This fruit is well known to curriers, who are in the habit of using it in preparing leather. It is employed also in the form of a liniment for itch-scabs and leprous spots; and a decoction of it with wheat, taken in drink, increases the milk in women when nursing. The root of this tree, so renowned for the numerous medicinal purposes to which it is applied, is pounded and taken in wine, in doses of two drachmæ, for the cure of stings inflicted by serpents: it has the effect, also, of removing spots upon the face, moles and freckles, as well as scars and bruises: a decoction of it in oil is productive of a similar effect. A decoction of it is given to drink for epilepsy, and to persons troubled with a disordered mind or suffering from vertigo, the dose being one drachma daily, for a whole year: taken in larger quantities, it is apt sometimes to disorder the senses. It is possessed, also, of one very remarkable property, applied with water in the same manner as bryonia, of extracting splintered bones, for which reason it is known to some persons by the name of white bryonia: the other kind, however, which is black, is found to answer the purpose better, in combination with honey and frankincense.

The white vine disperses incipient suppurations, ripens them when they are inveterate, and acts as a detergent: it operates also as an emmenagogue and diuretic. An electuary is prepared from it for asthma and pains in the sides, as also for convulsions and ruptures. Taken in drink for thirty days together, in doses of three oboli, it has the effect of reducing the spleen; and it is used, in combination with figs, for the cure of hangnails on the fingers. Applied with wine, it brings away the after-birth, and, taken in hydromel, in doses of one drachma, it carries off phlegm. The juice of the root should be extracted before the fruit ripens; applied either by itself or with meal of fitches, it imparts an improved complexion and a certain degree of suppleness to the

skin: it has the effect also of repelling serpents. The root itself, too, beaten up with a pulpy fig, will remove wrinkles on the body, if the person using it takes care to walk a couple of stadia immediately after the application; otherwise it would leave marks upon the skin, unless, indeed, it were washed off immediately with cold water. The black vine, too, is better for this purpose than the white one, as the latter is very apt to be pro- ductive of itching.

Detailed table of contents

CHAP. 17.

THE BLACK VINE, OTHERWISE CALLED BRYONA, CHIRONIA, GYNÆCANTHE,
OR APRONIA: THIRTY-FIVE REMEDIES.

For there is also a black vine, properly known as the “bryonia,” though by some persons it is called the “chironia,” and by others the “gynæcanthe,” or “apronia.” It differs only from the one previously mentioned in its colour, which, as already stated, is black. The shoots of this tree, which resemble asparagus in appearance, are preferred by Diodes for eating to real asparagus, as a diuretic and for its property of reducing the spleen. It is found growing in shrubberies or reed-beds more particularly. The root of it, which is black outside, and of the colour of box within, is even more efficacious for the extraction of splintered bones than the plant last mentioned; in addition to which, it has the property of being a specific for excoriations of the neck in cattle. It is said, too, that if a person plants it around a farm, it will be sure to keep hawks away, and to preserve the poultry-yard in perfect safety. Attached to the ankles, it tends to disperse the blood, congested or otherwise, which may have settled in those parts of the body, whether in human beings or in beasts of burden.

Thus much with reference to the various species of vines.

Detailed table of contents

CHAP. 18.

MUST: FIFTEEN REMEDIES.

The various kinds of must have different properties; some of them being black, some white, and others of intermediate shades of colour. There is a difference, too, between the kinds of must from which wine is made, and those from which raisin wine is prepared. The various degrees of care and attention on the part of the maker, render the differences that already exist, quite innumerable; we shall therefore content ourselves with taking a general view only of their medicinal uses.

Every kind of must is unwholesome to the stomach, but of a soothing nature to the venous system. Taken off at a draught, immediately after the bath, must is fatal in its effects. It acts as an antidote to cantharides and stings inflicted by serpents, those of the hæmorrhoids and the salamandra in particular. It is productive of head-ache, and is prejudicial to the throat, but it is good for the kidneys, liver, and inner coat of the bladder, by reason of its lubricating properties. It is particularly effectual also in cases of injuries inflicted by the insect known as the “buprestis.”

Taken with oil as a vomit, it neutralizes the bad effects of opium, milk that has curdled upon the stomach, hemlock, dorycnium, and other poisons. For all these purposes, however, white must is not so efficacious, while must prepared from raisins of the sun has a more pleasant flavour, and is productive of a less degree of oppression to the head.

CHAP. 19.

PARTICULARS RELATIVE TO WINE.

We have already described the various kinds of wine, the numerous differences which exist between them, and most of the properties which each kind possesses. There is no subject that presents greater difficulties than this, or, indeed, a more varied field for discussion, it being extremely difficult to pronounce whether wine is more generally injurious in its effects, or beneficial. And then, in addition to this, how very uncertain is it, whether, the moment we have drunk it, it will be productive of salutary results, or turn out no better than so much poison! However, it is only with reference to its medicinal properties, that we are now about to speak of it.

Asclepiades has composed a whole treatise (which has thence received its name) on the proper methods of administering wine; and the number of commentators who have since written on this treatise, is almost innumerable. For my own part, with all that gravity which becomes a Roman, and one zealous for the furtherance of liberal pursuits, I shall enter into a careful examination of this subject, not, indeed, in the character of a physician, but as a careful investigator of the effects which wine is likely to produce upon the health of man- kind. To treat, however, of the medicinal properties of each individual kind, would be a labour without end, and quite inexhaustible; the more so, as the opinions of medical men are so entirely at variance upon the subject.

Detailed table of contents

CHAP. 20.

THE SURRENTINE WINES: THREE REMEDIES. THE ALBAN WINES: TWO REMEDIES. THE FALERNIAN WINES: SIX REMEDIES.

Our ancestors set the highest value upon the wines of Surrentum; but at a later period the preference was given to the Alban, or the Falernian wines. More recently, again, other varieties of wine have come into fashion, quite in accordance with that most unreasonable mode of proceeding, according to which, each person, as he finds a wine most to his taste, extols it as superior to all others. Suppose, now, that all persons were quite agreed as to the superiority of some particular kind of wine, how small a proportion of mankind would be enabled to make use of it! As it is, even the rich never drink it in an unsophisticated state; the morals of the age being such, that it is the name only of a vintage that is sold, the wines being adulterated the very moment they enter the vat. Hence it is, by Hercules! — a thing truly astounding — that, in reality, a wine is more innoxious in its effects, in proportion as it enjoys a less extended renown. The three kinds, however, of which we have made mention, appear to have maintained, with the least diminution, their ancient repute.

The Falernian wine, it a person should be desirous to know the marked characteristics of wines according to age, is injurious to the health, either too new or too old; at fifteen years it begins to be of medium age. Falernian wine of this age, taken cold, is good for the stomach, but not when taken warm. For an inveterate cough and for quartan fevers, it is a good plan to drink it neat, fisting. There is no wine that quickens the action of the venous system so much as this; it acts astringently upon the bowels, and is feeding to the body. It has been thought, however, that this wine is productive of injury to the sight, and that it is far from beneficial to the nerves and the bladder.

The Alban wines are more salutary to the nervous system, but the sweet kinds are not so beneficial to the stomach. The rough wines of Alba are even better than those of Falernum, but they do not promote the digestion so well, and have a slight tendency to overload the stomach.

As to the Surrentine wines, they have no such effect upon the stomach, nor are they at all trying to the head; they have the property also of arresting defluxions of the stomach and intestines. The Cæcuban wines are no longer grown.

Detailed table of contents

CHAP. 21.

THE SETINE WINES; ONE OBSERVATION UPON THEM. THE STATAN WINES; ONE OBSERVATION UPON THEM. THE, SIGNIAN WINES; ONE REMEDY.

Among the wines, however, which still exist, those of Setia promote the digestion, having more strength than the Surrentine wines, and more roughness than those of Alba. The wines of Falernum are not so powerful. Those of Stata are but very little inferior in quality to the wines already mentioned. It is universally agreed that the wines of Signia are extremely beneficial in cases of derangement of the bowels.

Detailed table of contents

CHAP. 22.

OTHER WINES: SIXTY-FOUR REMEDIES.

As to the other wines, they may be spoken of in general terms. By the use of wine, the human vigour, blood, and complexion are improved. It is wine that makes up for all the difference between the middle or temperate zone, and those which lie on either side of it, the juice of the vine conferring as much vigour and robustness upon the inhabitants of our part of the earth as the rigorousness of the climate does upon the people there. Milk, used as a beverage, strengthens the bones, liquids extracted from the cereals nourish the sinews, and water imparts nutriment to the flesh: hence it is that persons who confine themselves to these several liquids as a beverage, are of a less ruddy complexion than the winedrinker, less robust, and less able to endure fatigue. By the use of wine in moderation the sinews are strengthened, but taken in excess it proves injurious to them; the same, too, with the eves. Wine refreshes the stomach, sharpens the appetite, takes off the keen edge of sorrows and anxieties, warms the body, acts beneficially as a diuretic, and invites sleep. In addition to these properties, it arrests vomiting, and we find that pledgets of wool, soaked in wine, and applied to abscesses, are extremely beneficial. According to Asclepiades, the virtues possessed by wine are hardly equalled by the majestic attributes of the gods themselves.

Old wine bears admixture with a larger quantity of water, and acts more powerfully as a diuretic, though at the same time it is less effectual for quenching thirst. Sweet wine, again, is less inebriating, but stays longer on the stomach, while rough wine is more easy of digestion. The wine that becomes mellow with the greatest rapidity is the lightest, and that which becomes sweeter the older it is, is not so injurious to the nerves. Wines that are rich and black, are not so beneficial to the stomach; but, at the same time, they are more feeding to the body. Thin-bodied rough wines are not so feeding, but are more wholesome to the stomach, and pass off more speedily by urine, though they are all the more liable to fly to the head; a remark which will apply, once for all, to liquids of every kind.

Wine that has been mellowed by the agency of smoke is extremely unwholesome — a fraudulent method of preparation that has been invented in the wine-lofts of the retail dealers. At the present day, however, this plan is adopted in private families even, when it is wished to give the appearance of maturity to wines that have become carious. Indeed, this term *carious* has been used very appositely by the ancients with reference to wines; for we find that in the case of wood even, smoke exercises a caustic effect upon the carious parts, and eats them away; and yet we, on the other hand, persuade ourselves that an adventitious age may be imparted to wines by the bitter twang derived from smoke!

Those wines which are extremely pale, become more wholesome the older they are. The more generous a wine is, the thicker it becomes with age; while, at the same time, it contracts a bitter flavour, which is far from exercising a beneficial effect upon the health. To season another wine, that is not so old, with this, is nothing less than to make an unwholesome preparation. The more of its own natural flavour a wine possesses, the more wholesome it is; and the best age for a wine is that which naturally belongs to it, a medium age being the one that is the most generally esteemed.

[Detailed table of contents](#)

CHAP. 23.

SIXTY-ONE OBSERVATIONS RELATIVE TO WINE.

Persons whose wish it is to make flesh, or to keep the bowels relaxed, will do well to drink while taking their food. Those, on the other hand, who wish to reduce themselves, or prevent the bowels from being relaxed, should abstain from drinking while taking their meals, and drink but a very little only when they have done eating. To drink wine fasting is a fashion of recent introduction only, and an extremely bad one for persons engaged in matters of importance, and requiring a continued application of the mental faculties. Wine, no doubt, was taken fasting in ancient times, but then it was as a preparative for sleep and repose from worldly cares; and it is for this reason that, in Homer, we find Helen presenting it to the guests before the repast. It is upon this fact, too, that the common proverb is founded, which says that “wisdom is obscured by wine.” It is to wine that we men are indebted for being the only animated beings that drink without being thirsty. When drinking wine, it is a very good plan to take a draught of water every now and then; and to take one long draught of it at the last, cold water taken internally having the effect of instantaneously dispelling inebriation.

It is strongly recommended by Hesiod to drink undiluted wine for twenty days before the rising of the Dog-star, and as many after. Pure wine, too, acts as an antidote to hemlock, coriander, henbane, mistletoe, opium, mercury, as also to stings inflicted by bees, wasps, hornets, the phalangium, serpents, and scorpions; all kinds of poison, in fact, which are of a cold nature, the venom of the hæmorrhoids and the prester, in particular, and the noxious effects of fungi. Undiluted wine is good, too, in cases of flatulency, gnawing pains in the thoracic organs, excessive vomitings at the stomach, fluxes of the bowels and intestines, dysentery, excessive perspirations after prolonged fits of coughing, and defluxions of various kinds. In the cardiac disease, it is a good plan to apply a sponge soaked in neat wine to the left breast: in all these cases, however, old white wine is the best. A fomentation of hot wine applied to the genitals of beasts of burden is found to be very beneficial; and, introduced into the mouth, with the aid of a horn, it has the effect of removing all sensations of fatigue. It is asserted that in apes, and other quadrupeds with toes, the growth will be impeded if they are accustomed to drink undiluted wine.

Detailed table of contents

CHAP. 24.

IN WHAT MALADIES WINE SHOULD BE ADMINISTERED; HOW IT SHOULD BE ADMINISTERED, AND AT WHAT TIMES.

We shall now proceed to speak of wine in relation to its medicinal uses. The wines of Campania which have the least body, are the most wholesome beverage for persons of rank and station; and for the lower classes the best kind of wine is that which is the most pleasant to the person who drinks it, provided he is in robust health. For persons of all ranks, however, the most serviceable wine is that the strength of which has been reduced by the strainer; for we must bear in mind that wine is nothing else but juice of grapes which has acquired strength by the process of fermentation. A mixture of numerous kinds of wine is universally bad, and the most wholesome wine of all is that to which no ingredient has been added when in a state of must; indeed, it is still better if the vessels even in which it is kept have never been pitched. As to wines which have been treated with marble, gypsum, or lime, where is the man, however robust he may be, that has not stood in dread of them?

Wines which have been prepared with sea-water are particularly injurious to the stomach, nerves, and bladder. Those which have been seasoned with resin are generally looked upon as beneficial to a cold stomach, but are considered unsuitable where there is a tendency to vomit: the same, too, with must, boiled grape-juice, and raisin wine. New wines seasoned with resin are good for no one, being productive of vertigo and head-ache: hence it is that the name of "crapula" has been given equally to new resined wines, and to the surfeit and head-ache which they produce.

The wines above mentioned by name, are good for cough and catarrh, as also for coeliac affections, dysentery, and the catamenia. Those wines of this sort which are red or black, are more astringent and more heating than the others. Wines which have been seasoned with pitch only, are not so injurious; but at the same time we must bear in mind that pitch is neither more nor less than resin liquefied by the action of fire. These pitched wines are of a heating nature, promote the digestion, and act as a purgative; they are good, also, for the chest and the bowels, for pains in the uterus, if there are no signs of fever, for inveterate fluxes, ulcerations, ruptures, spasms, suppurated abscesses, debility of the sinews, flatulency, cough, asthma, and sprains, in which last case they are applied in uncleansed wool. For all these purposes the wine is preferred which has naturally the flavour of pitch, and is thence known as "picatum:" it is generally agreed, however, that the produce of the vine called "helvonnaca," if taken in too large a quantity, is trying to the head.

In reference to the treatment of fever, it is well known that wine should never be given, unless the patient is an aged person, or the symptoms are beginning to abate. In cases of acute fever, wine must never be given, under

any circumstance, except when there is an evident remission of the attack, and more particularly if this takes place in the night, for then the danger is diminished by one half, there being the probability of the patient sleeping off the effects of the wine. It is equally forbidden, also, to females just after delivery or a miscarriage, and to patients suffering from over-indulgence of the sexual passions; nor should it be given in cases of head-ache, of maladies in which the attacks are attended with chills at the extremities, of fever accompanied with cough, of tremulousness in the sinews, of pains in the fauces, or where the disease is found to concentrate itself in the iliac regions. Wine is strictly forbidden, too, in cases of induration of the thoracic organs, violent throbbings of the veins, opisthotony, tetanus, asthma, and hardness of breathing attended with fever.

Wine is far from beneficial for a patient, when the eyes are fixed and rigid, and when the eyelids are immoveable, or else relaxed and heavy; in cases, too, where, with an incessant nictation, the eyes are more than usually brilliant, or where the eyelids refuse to close — the same, too, if that symptom should occur in sleep — or where the eyes are suffused with blood, or congealed matter makes its appearance in the corners of those organs. The same rule should be observed, also, when the tongue is heavy and swollen, or when there is an impediment from time to time in the speech, when the urine is passed with difficulty, or when a person has been seized with a sudden fright, with spasms, or recurrent fits of torpor, or experiences seminal discharges during sleep.

[Detailed table of contents](#)

CHAP. 25.

NINETY-ONE OBSERVATIONS WITH REFERENCE TO WINE.

It is a well-ascertained fact, that in the cardiac disease the only resource is wine. According to some authorities, however, wine should only be given when the attacks come on, while others, again, are of opinion, that it must only be administered between the attacks; it being the object with the former to arrest the profuse perspirations, while the latter base their practice on an impression that it may be given with more safety at a moment when the malady has diminished in intensity; and this I find is the opinion entertained by most people. In all cases, wine must only be administered just after taking food, never after sleep, and under no circumstances after any other kind of drink, or in other words, only when the patient is thirsty; in no case whatever should it be given, except at the very last extremity. Wine is better suited to males than to females, to aged people than to youths, to youths than to children, and to persons who are used to it than to those who are not in the habit of taking it; winter, too, is a better time for using it than summer. As to the quantity to be prescribed, and the proportion of water to be mixed with it, that depends entirely upon the strength of the wine; it is generally thought, however, that the best proportions are one cyathus of wine and two of water. If, however, there is a derangement of the stomach, and if the food does not pass downward, the wine must be given in a larger proportion.

Detailed table of contents

CHAP. 26.

ARTIFICIAL WINES.

Among the artificial wines, the preparation of which we have described, [there are some which], I think, are no longer made; in addition to which, it would be a mere loss of time to enlarge upon their medicinal effects, having expatiated elsewhere upon the properties of the various elements of which they are composed. And then, besides, the conceits of the medical men in relation to these wines have really passed all bounds; they pretend, for instance, that a wine extracted from turnips is good for recruiting the exhausted strength, after exercises in arms or on horseback; and, not to speak of other preparations, they attribute a similar effect to wine of juniper. Who is there, too, that would think of looking upon wormwood wine as superior in its effects to wormwood itself?

I shall pass in silence the rest of these preparations, and among them palm wine, which is injurious to the head, and is beneficial only as a laxative to the bowels, and as a cure for spitting of blood. We cannot, however, look upon the liquor which we have spoken of under the name of “bion,” as being an artificial wine; for the whole art of making it consists merely in the employment of grapes before they have arrived at maturity. This preparation is extremely good for a deranged stomach or an imperfect digestion, as also for pregnancy, fainting fits, paralysis, fits of trembling, vertigo, gripings of the bowels, and sciatica. It is said, too, that in times of pestilence, and for persons on a long journey, this liquid forms a beverage of remarkable efficacy.

[Detailed table of contents](#)

CHAP. 27.

VINEGAR: TWENTY-EIGHT REMEDIES.

Wine, even when it has lost its vinous properties, still retains some medicinal virtues. Vinegar possesses cooling properties in the very highest degree, and is no less efficacious as a resolvent; it has the property, too, of effervescing, when poured upon the ground. We have frequently had occasion, and shall again have occasion, to mention the various medicinal compositions in which it forms an ingredient. Taken by itself it dispels nausea and arrests hiccup, and if smelt at, it will prevent sneezing; retained in the mouth, it prevents a person from being inconvenienced by the heat of the bath. It is used as a beverage also, in combination with water, and employed as a gargle, it is found by many to be very wholesome to the stomach, particularly convalescents and persons suffering from sun-stroke; used as a fomentation, too, this mixture is extremely beneficial to the eyes. Vinegar is used remedially when a leech has been swallowed; and it has the property of healing leprous sores, scorbutic eruptions, running ulcers, wounds inflicted by dogs, scorpions, and scolopendræ, and the bite of the shrew-mouse. It is good, too, as a preventive of the itching sensations produced by the venom of all stinging animals, and as an antidote to the bite of the millepede.

Applied warm in a sponge, in the proportion of three sextarii to two ounces of sulphur or a bunch of hyssop, vinegar is a remedy for maladies of the fundament. To arrest the hemorrhage which ensues upon the operation of lithotomy, and, indeed, all other operations of a similar nature, it is usual to apply vinegar in a sponge, and at the same time to administer it internally in doses of two cyathi, the very strongest possible being employed. Vinegar has the effect also of dissolving coagulated blood; for the cure of lichens, it is used both internally and externally. Used as an injection, it arrests looseness of the bowels and fluxes of the intestines; it is similarly employed, too, for procidence of the rectum and uterus.

Vinegar acts as a cure for inveterate coughs, defluxions of the throat, hardness of breathing, and looseness of the teeth: but it acts injuriously upon the bladder and the sinews, when relaxed. Medical men were for a long time in ignorance how beneficial vinegar is for the sting of the asp; for it was only recently that a man, while carrying a bladder of vinegar, happening to be stung by an asp upon which he trod, found to his surprise that whenever he put down the bladder he felt the sting, but that when he took it up again, he seemed as though he had never been hurt; a circumstance which at once suggested to him the remedial properties of the vinegar, upon drinking some of which he experienced a cure. It is with vinegar, too, and nothing else, that persons rinse the mouth after sucking the poison from a wound. This liquid, in fact, exercises a predominance not only upon various articles of food, but

upon many other substances as well. Poured upon rocks in considerable quantities, it has the effect of splitting them, when the action of fire alone has been unable to produce any effect thereon. As a seasoning, too, there is no kind that is more agreeable than vinegar, or that has a greater tendency to heighten the flavour of food. When it is employed for this purpose, its extreme tartness is modified with burnt bread or wine, or else it is heightened by the addition of pepper, and of laser; in all cases, too, salt modifies its strength.

While speaking of vinegar, we must not omit to mention a very remarkable case in connexion with it: in the latter years of his life, M. Agrippa was dreadfully afflicted with gout, so much so, in fact, that he was quite unable to endure the torments to which he was subjected. Upon this, guided by the ominous advice of one of his medical attendants, though unknown to Augustus, at the moment of an extremely severe attack he plunged his legs into hot vinegar, content to purchase exemption from such cruel torments as he suffered, if even at the price of all use and sensation in those limbs, * * * *

*,

Detailed table of contents

CHAP. 28. (2.)

SQUILL VINEGAR: SEVENTEEN REMEDIES.

Squill vinegar is the more esteemed, the older it is. In addition to the properties which we have already mentioned, it is useful in cases where the food turns sour upon the stomach, a mere taste of it being sufficient to act as a corrective. It is good, too, when persons are seized with vomiting, while fasting, having the effect of indurating the passages of the throat and stomach. It is a corrective, also, of bad breath, strengthens the teeth and gums, and improves the complexion.

Used as a gargle, squill vinegar remedies hardness of hearing, and opens the passages of the ears, while at the same time it tends to improve the sight. It is very good, too, for epilepsy, melancholy, vertigo, hysterical suffocations, blows, falls with violence, and extravasations of blood in consequence, as also for debility of the sinews, and diseases of the kidneys. In cases of internal ulceration, however, the use of it must be avoided.

[Detailed table of contents](#)

CHAP. 29.

OXYMELI: SEVEN REMEDIES.

The following, as we learn from Dieuches, was the manner in which oxymeli was prepared by the ancients. In a cauldron they used to put ten minæ of honey, five heminæ of old vinegar, a pound and a quarter of sea-salt, and five sextarii of rain-water; the mixture was then boiled together till it had simmered some ten times, after which it was poured off, and put by for keeping. Asclepiades, however, condemned this preparation, and put an end to the use of it, though before his time it used to be given in fevers even. Still, however, it is generally admitted that it was useful for the cure of stings inflicted by the serpent known as the “seps,” and that it acted as an antidote to opium and mistletoe. It was usefully employed also, warm, as a gargle for quinsy and maladies of the ears, and for affections of the mouth and throat; for all these purposes, however, at the present day, oxalme is employed, the best kind of which is made with salt and fresh vinegar.

Detailed table of contents

CHAP. 30.

SAPA: SEVEN REMEDIES.

Sapa, has a close affinity with wine, being nothing else but must boiled down to one third: that which is prepared from white must is the best. It is used medicinally in cases of injuries inflicted by cantharides, the buprestis, the pinecaterpillars known as pityocampæ, salamanders, and all venomous bites and stings. Taken with onions it has the effect of bringing away the dead fœtus and the after-birth. According to Fabianus, it acts as a poison, if taken by a person fasting, immediately after the bath.

[Detailed table of contents](#)

CHAP. 31.

LEES OF WINE: TWELVE REMEDIES.

Next in the natural order come the lees of these several liquids. The lees of wine are so extremely powerful as to prove fatal to persons on descending into the vats. The proper precaution for preventing this, is to let down a light first, which so long as it refuses to burn, is significant of danger. Wine-lees, in an unrinsed state, form an ingredient in several medicinal preparations: with an equal proportion of iris, a liniment is prepared from them for purulent eruptions; and either moist or dried, they are used for stings inflicted by the phalangium, and for inflammations of the testes, marmillæ, or other parts of the body. A decoction of wine-lees is prepared, too, with barley-meal and powdered frankincense; after which it is first parched and then dried. The test of its being properly boiled, is its imparting, when cold, a burning sensation to the tongue. When left exposed to the air, wine-lees very rapidly lose their virtues; which, on the other hand, are greatly heightened by the action of fire.

Wine-lees are very useful, too, boiled with figs, for the cure of lichens and cutaneous eruptions; they are applied also in a similar manner to leprous sores and running ulcers. Taken in drink, they act as an antidote to the poison of fungi, and more particularly if they are undiluted; boiled and then rinsed, they are used in preparations for the eyes. They are employed also topically for diseases of the testes and generative organs, and are taken in wine for strangury. When wine-lees have lost their strength, they are still useful for cleansing the body and scouring clothes, in which case they act as a substitute for gum acacia.

Detailed table of contents

CHAP. 32.

LEES OF VINEGAR: SEVENTEEN REMEDIES.

The lees of vinegar, as a matter of course, considering the material from which they are derived, are much more acrid than these of wine, and more caustic in their effects. This substance prevents the increase of suppuration, and, employed topically, is good for the stomach, intestines, and regions of the abdomen. It has the property also of arresting fluxes of those parts, and the catamenia when in excess; it disperses inflamed tumours which have not come to a head, and is a cure for quinsy. Applied with wax, it is curative of erysipelas. It reduces swellings of the mamillæ when gorged with milk, and removes malformed nails. Employed with polenta, it is very efficacious for the cure of stings inflicted by the serpent called cerastes; and in combination with melanthium, it heals bites inflicted by crocodiles and dogs.

Vinegar lees, too, by being subjected to the action of fire, acquire additional strength. Mixed in this state with oil of mastich, and applied to the hair, they turn it red in a single night. Applied with water in linen, as a pessary, they act as a detergent upon the uterus.

[Detailed table of contents](#)

CHAP. 33.

LEES OF SAPA: FOUR REMEDIES.

The lees of sapa are used for the cure of burns, it being the best plan to employ with them the down that grows on the reed; a decoction too, of these lees, is good for the cure of an inveterate cough. They are boiled also in a saucepan with salt and grease as an ointment for tumours of the jaws and neck.

[Detailed table of contents](#)

CHAP. 34. (3.)

THE LEAVES OF THE OLIVE: TWENTY-THREE REMEDIES.

The next rank, after the vine, clearly belongs to the olive. The leaves of the olive-tree are astringent, detergent, and binding in the highest degree. Chewed and applied to sores, they are of a healing nature; and applied topically with oil, they are good for head-ache. A decoction of them with honey makes a good liniment for such parts of the body as have been subjected to cauterization, as also for inflammations of the gums, whitlows, and foul and putrid ulcers: combined with honey, they arrest discharges of blood from the nervous parts of the body. The juice of olive leaves is efficacious for carbuncular ulcers and pustules about the eyes, and for procidence of the pupil; hence it is much employed in the composition of eye-salves, having the additional property of healing inveterate runnings of the eyes, and ulcerations of the eyelids.

This juice is extracted by pouring wine and rain-water upon the leaves, and then pounding them; after which the pulp is dried and divided into lozenges. Used with wool, as a pessary, this preparation arrests menstruation when in excess, and is very useful for the treatment of purulent sores, condylomata, erysipelas, spreading ulcers, and epinyctis.

[Detailed table of contents](#)

CHAP. 35

THE BLOSSOM OF THE OLIVE: FOUR REMEDIES.

The blossom, of too, of the olive-tree possesses similar properties. The young branches are burnt when just beginning to blossom, and of the ashes a substitute for spodium is made, upon which wine is poured, and it is then burnt afresh. To suppurations and inflamed tumours these ashes are applied, or else the leaves, beaten up with honey; for the eyes, they are used with polenta. The juice which exudes from the wood, when burnt in a green state, heals lichens, scaly eruptions, and running ulcers.

As to the juice which exudes naturally from the olivetree, and more particularly that of Æthiopia, we cannot be sufficiently surprised that authors should have been found to recommend it as an application for tooth-ache, and to tell us at the same time that it is a poison, and even that we must have recourse to the wild olive for it. The bark of the roots of the olive, as young and tender a tree as possible being selected, scraped and taken every now and then in honey, is good for patients suffering from spitting of blood and purulent expectorations. The ashes of the tree itself, mixed with axle-grease, are useful for the cure of tumours, and heal fistulas by the extraction of the vicious humours which they contain.

Detailed table of contents

CHAP. 36.

WHITE OLIVES: FOUR REMEDIES. BLACK OLIVES: THREE REMEDIES.

White olives are wholesome for the upper regions of the stomach, but not so good for the bowels. Eaten by themselves, habitually as a diet, quite fresh and before they are preserved, they are remarkably serviceable, having the effect of curing gravel, and of strengthening the teeth when worn or loosened by the use of meat.

Black olives, on the other hand, are not so wholesome for the upper regions of the stomach, but are better for the bowels; they are not good, however, for the head or for the eyes. Both kinds, pounded and applied topically, are good for the cure of burns, but the black olive is sometimes chewed first, and instantly applied to the sore, for the purpose of preventing blisters from forming. Colymbades act as a detergent for foul ulcers, but they are bad for persons suffering from strangury.

[Detailed table of contents](#)

CHAP. 37.

AMURCA OF OLIVES: TWENTY-ONE REMEDIES.

As to the amurca of olives, we might appear to have said enough on the subject already, taking Cato as our guide; it remains, however, to speak of the medicinal uses of this substance. It is extremely serviceable as a strengthener of the gums, and for the cure of ulcers of the mouth; it has the effect, also, of strengthening loose teeth in the sockets, and an application of it is good for erysipelas and spreading ulcers. For chilblains, the amurca of the black olive is the best, as also as a fomentation for infants; that of the white olive is used, with wool, as a pessary for affections of the uterus. Of both kinds, however, the amurca is much more serviceable when boiled; this being done in a vessel of Cyprian copper, to the consistency of honey. Thus prepared, it is used, according to the necessities of the case, with either vinegar, old wine, or honied wine, for the treatment of maladies of the mouth, teeth, and ears, and for running ulcers, diseases of the generative organs, and chaps on various parts of the body. It is employed topically, for the cure of wounds, in a linen pledget, and for sprains, in wool: as a medicament, it is of great utility, more particularly when old, as in such case it effects the cure of fistula.

It is used as an injection for ulcerations of the fundament, the generative organs, and the uterus, and is employed topically for incipient gout and diseases of the joints. Boiled down again, with omphacium, to the consistency of honey, it extracts decayed teeth; and, in combination with a decoction of lupines and the plant chamæleon, it is a marvellous cure for itch in beasts of burden. Fomentations of amurca in a raw state are extremely good for gout.

Detailed table of contents

CHAP. 38. (4.)

THE LEAVES OF THE WILD OLIVE: SIXTEEN REMEDIES.

The leaves of the wild olive are possessed of similar properties. The spodium that is made by burning the young branches is of remarkable efficacy for arresting fluxes; it allays inflammations of the eyes also, acts as a detergent upon ulcerous sores, makes the flesh grow on wounds from which it has been removed, and acts gently as a caustic upon fleshy excrescences, drying them up and making them cicatrize. The rest of its properties are similar to those of the cultivated olive. There is, however, one peculiarity in it; the leaves, boiled with honey, are given in doses of a spoonful for spitting of blood. The oil, too, of the wild olive is more acrid, and possesses greater energy than that of the cultivated olive; hence it is that it is usual to rinse the mouth with it for the purpose of strengthening the teeth.

The leaves, too, are applied topically, with wine, to whitlows, carbuncles, and all kinds of gatherings; and, with honey, to sores which require a detergent. Both a decoction of the leaves and the natural juices of the wild olive form ingredients in medicaments for the eyes; and the latter are found useful as an injection for the ears, in the case of purulent discharges even. From the blossom of the wild olive a liniment is prepared for condylomata and epinyctis: it is applied also to the abdomen, with barley-meal, for fluxes, and to the head, with oil, for head-ache. In cases where the scalp becomes detached from the cranium, the young branches, boiled and applied with honey, have a healing effect. These branches, too, when arrived at maturity, taken with the food, arrest diarrhœa: parched and beaten up with honey, they act as a detergent upon corroding sores, and bring carbuncles to a head and dispers them.

[Detailed table of contents](#)

CHAP. 39.

OMPHACIUM: THREE REMEDIES.

As to olive oil, we have abundantly treated of its nature and elements already. It now remains to speak of the medicinal properties of the various kinds of oil. The most useful of all is omphacium, and next to that, green oil; in addition to which, we may remark that oil ought to be as fresh as possible, except in cases where old oil is absolutely required. For medicinal purposes, too, oil should be extremely fluid, have an agreeable smell, and be free from all taste, just the converse, in fact, of the property which we look for in food. Omphacium is good for the gums, and if kept from time to time in the mouth, there is nothing better as a preservative of the whiteness of the teeth. It checks profuse perspirations.

Detailed table of contents

CHAP. 40.

OIL OF CENANTHE: TWENTY-EIGHT REMEDIES.

Oil of œnanthe has just the same properties as oil of roses. Like oil in general, it makes the body supple, and imparts to it strength and vigour; it is injurious to the stomach, promotes the increase of ulcers, irritates the fauces, and deadens the effect of all poisons, white-lead and gypsum in particular, if taken in hydromel or a decoction of dried figs. Taken with water, it is good as an antidote to the effects of opium, and to injuries inflicted by cantharides, the buprestis, the salamandra, and the pine caterpillar. Taken pure as an emetic, it is highly esteemed as an antidote in all the before-mentioned cases. It is also a refreshing remedy for extreme lassitude, and for fits of shivering from cold. Taken warm, in doses of six cyathi, and more particularly when boiled with rue, it relieves gripings of the stomach and expels intestinal worms, Taken in doses of one hemina with wine and warm water, or else with barley water, it acts as a purgative upon the bowels. It is useful, also, in the composition of plasters for wounds, and it cleanses the complexion of the face. Injected into the nostrils of oxen, till it produces eructation, it cures attacks of flatulency.

When old it is of a more warming nature than when new, and acts more energetically as a sudorific, and as a resolvent for indurations. It is very efficacious in cases of lethargy, and more particularly in the decline of the disease. Mixed with an equal proportion of honey which has not been smoked, it contributes in some degree to the improvement of the sight. It is a remedy, also for head-ache; and, in combination with water, for the burning attacks in fevers. If old oil should happen not to be at hand, the new oil is boiled to act as a substitute for it.

Detailed table of contents

CHAP. 41.

CASTOR OIL: SIXTEEN REMEDIES.

Castor oil, taken with an equal quantity of warm water, acts as a purgative upon the bowels. It is said, too, that as a purgative this oil acts more particularly upon the regions of the diaphragm. It is very useful for diseases of the joints, all kinds of indurations, affections of the uterus and ears, and for burns: employed with the ashes of the murex, it heals itch-scabs and inflammations of the fundament. It improves the complexion also, and by its fertilizing tendencies promotes the growth of the hair. The cicus, or seed from which this oil is made, no animal will touch; and from these grape-like seeds wicks are made, which burn with a peculiar brilliancy; the light, however, that is produced by the oil is very dim, in consequence of its extreme thickness. The leaves are applied topically with vinegar for erysipelas, and fresh-gathered, they are used by themselves for diseases of the mamillæ and defluxions; a decoction of them in wine, with polenta and saffron, is good for inflammations of various kinds. Boiled by themselves, and applied to the face for three successive days, they improve the complexion.

[Detailed table of contents](#)

CHAP. 42.

OIL OF ALMONDS: SIXTEEN REMEDIES.

Oil of almonds is of a purgative and emollient nature; it effaces wrinkles on the skin, improves the complexion, and, in combination with honey, removes spots on the face. A decoction of it with oil of roses, honey, and pomegranate rind, is good for the ears, and exterminates the small worms that breed there; it has the effect also, of dispelling hardness of hearing, recurrent tinglings and singing in the ears, and is curative of head-ache and pains in the eyes. Used with wax, it cures boils, and scorches by exposure to the sun; in combination with wine it heals running ulcers and scaly eruptions, and with melilote, condylomatous swellings. Applied by itself to the head, it invites sleep.

Detailed table of contents

CHAP. 43.

OIL OF LAUREL: NINE REMEDIES.

As to oil of laurel, the fresher and greener it is, the more valuable are its properties. It is of a heating nature, and is consequently applied, warm, in a pomegranate rind, for paralysis, spasms, sciatica, bruises, head-ache, catarrhs of long standing, and diseases of the ears.

Detailed table of contents

CHAP. 44.

OIL OF MYRTLE: TWENTY REMEDIES.

Oil of myrtle has similar properties. It is of an astringent and indurative nature; mixed with the scoria of copper, and wax, it cures diseases of the gums, tooth-ache, dysentery, ulcerations of the uterus, affections of the bladder, inveterate or running ulcers, eruptions, and burns. It exercises a healing effect also, upon excoriations, scaly eruptions, chaps, condylomata, and sprains, and it neutralizes offensive odours of the body. This oil is an antidote to cantharides, the buprestis, and other dangerous poisons of a corrosive nature.

[Detailed table of contents](#)

CHAP. 45.

OIL OF CHAMÆMYRSINE OR OXYMYRSINE; OIL OF CYPRESS; OIL OF CITRUS;
OIL OF WALNUTS; OIL OF CNIDIUM: OIL OF MASTICH; OIL OF BALANUS;
VARIOUS REMEDIES.

Oil of chamæmyrsine, or oxymyrsine, possesses similar properties. Oil of cypress also, produces the same effects as oil of myrtle, and the same as to oil of citrus. Oil of walnuts, which we have previously mentioned as being called “caryinon,” is good for alopecia, and is injected into the ears for the cure of hardness of hearing. Used as a liniment, it relieves head-ache; but in other respects it is of an inert nature and disagreeable taste; indeed, if part only of one of the kernels should happen to be decayed, the whole making is spoilt. The oil extracted from the grain of Cnidos has similar properties to castor oil. Oil of mastich is very useful as an ingredient in the medicinal preparation known as “acopum;” indeed it would be fully as efficacious as oil of roses, were it not found to be somewhat too styptic in its effects. It is employed in cases of too profuse perspiration, and for the cure of pimples produced thereby. It is extremely efficacious also or itch in beasts of burden. Oil of balanus removes spots on the skin, boils, freckles, and maladies of the gums.

Detailed table of contents

CHAP. 46.

THE CYPRUS, AND THE OIL EXTRACTED FROM IT; SIXTEEN REMEDIES.
GLEUCINUM: ONE REMEDY.

We have already enlarged upon the nature of the cyprus, and the method of preparing oil of cyprus. This oil is naturally warming, and relaxes the sinews. The leaves of the tree are used as an application to the stomach, and the juice of them is applied in a pessary for irritations of the uterus. Fresh gathered and chewed, the leaves are applied to running ulcers of the head, ulcerations of the mouth, gatherings, and condylomatous sores. A decoction of the leaves is very useful also for burns and sprains. Beaten up and applied with the juice of the strutheum, they turn the hair red. The blossoms, applied to the head with vinegar, relieve head-ache, and the ashes of them, burnt in a pot of raw earth, are curative of corrosive sores and putrid ulcers, either employed by themselves, or in combination with honey. The odour exhaled by these blossoms induces sleep.

The oil called “gleucinum” has certain astringent and refreshing properties similar to those of oil of œnanthe.

Detailed table of contents

CHAP. 47.

OIL OF BALSAMUM: FIFTEEN REMEDIES.

The oil of balsamum is by far the most valuable of them all, as already stated by us, when treating of the unguents. It is extremely efficacious for the venom of all kinds of serpents, is very beneficial to the eyesight, disperses films upon the eyes, assuages hardness of breathing, and acts emolliently upon all kinds of gatherings and indurations. It has the effect, also, of preventing the blood from coagulating, acts as a detergent upon ulcers, and is remarkably beneficial for diseases of the ears, head-ache, trembling, spasms, and ruptures. Taken in milk, it is an antidote to the poison of aconite, and used as a liniment upon the access of the shivering fits in fevers, it modifies their violence. Still, however, it should be used but sparingly, as it is of a very caustic nature, and, if not employed in moderation, is apt to augment the malady.

Detailed table of contents

CHAP. 48.

MALOBATHRUM: FIVE REMEDIES.

We have already spoken, also, of the nature of malobathrum, and the various kinds of it. It acts as a diuretic, and, sprinkled in wine upon the eyes, it is used very advantageously for defluxions of those organs. It is applied also to the forehead, for the purpose of promoting sleep; but it acts with still greater efficacy, if the nostrils are rubbed with it, or if it is taken in water. The leaves, placed beneath the tongue, impart a sweetness to the mouth and breath, and put among clothes, they produce a similar effect.

[Detailed table of contents](#)

CHAP. 49.

OIL OF HENBANE: TWO REMEDIES. OIL OF LUPINES: ONE REMEDY. OIL OF NARCISSUS: ONE REMEDY. OIL OF RADISHES: FIVE REMEDIES. OIL OF SESAME: THREE REMEDIES. OIL OF LILIES: THREE REMEDIES. OIL OF SELGA: ONE REMEDY. OIL OF IGUVIUM: ONE REMEDY.

Oil of henbane is of an emollient nature, but it is bad for the nerves; taken in drink, it disturbs the brain. Thermal- num, or oil of lupines, is emollient, and very similar to oil of roses in its effects. As to oil of narcissus, we have already spoken of it when describing that flower. Oil of radishes cures phthiriasis contracted in a long illness, and removes roughness of the skin upon the face. Oil of sesame is curative of pains in the ears, spreading ulcers, and the cancer known as “cacoethes.” Oil of lilies, which we have previously mentioned as being called oil of Phaselis and oil of Syria, is extremely good for the kidneys and for promoting perspiration, as also as an emollient for the uterus, and as tending to bring internal tumours to a head. As to oil of Selga, we have already spoken of it as being strengthening to the tendons which is the case, also, with the herbaceous oil which the people of Iguvium sell, on the Flaminian Way.

Detailed table of contents

CHAP. 50.

ELÆOMELI: TWO REMEDIES. OIL OF PITCH: TWO REMEDIES.

Elæomeli, which, as we have already stated, exudes from the olive-trees of Syria, has a flavour like that of honey, but not without a certain nauseous taste. It relaxes the bowels, and carries off the bilious secretions more particularly, if taken in doses of two cyathi, in a semisextarius of water. After drinking it, the patient falls into a torpor, and requires to be aroused every now and then. Persons, when about to drink for a wager, are in the habit of taking a cyathus of it, by way of prelude. Oil of pitch is employed for the cure of cough, and of itch in cattle.

[Detailed table of contents](#)

CHAP. 51.

THE PALM: NINE REMEDIES.

Next in rank after the vine and the olive comes the palm. Dates fresh-gathered have an inebriating effect, and are productive of head-ache; when dried, they are not so injurious. It would appear, too, that they are not wholesome to the stomach; they have an irritating effect on coughs, but are very nourishing to the body. The ancients used to give a decoction of them to patients, as a substitute for hydromel, with the view of recruiting the strength and allaying thirst, the Thebaic date being held in preference for the purpose. Dates are very use- ful, too, for persons troubled with spitting of blood, when taken in the food more particularly. The dates called caryotæ, in combination with quinces, wax, and saffron, are applied topically for affections of the stomach, bladder, abdomen, and in- testines: they are good for bruises also. Date-stones, burnt in a new earthen vessel, produce an ash which, when rinsed, is employed as a substitute for spodium, and is used as an ingredient in eye-salves, and, with the addition of nard, in washes for the eye-brows.

Detailed table of contents

CHAP. 52. (5.)

THE PALM WHICH PRODUCES MYROBALANUM: THREE REMEDIES.

Of the palm which produces myrobalanum, the most esteemed kind is that grown in Egypt; the dates of which, unlike those of the other kinds, are without stones. Used with astringent wine, they arrest diarrhœa and the catamenia, and promote the cicatrization of wounds.

Detailed table of contents

CHAP. 53.

THE PALM CALLED ELATE: SIXTEEN REMEDIES.

The palm called “elate,” or “spathe,” furnishes its buds, leaves, and bark for medicinal purposes. The leaves are applied to the thoracic regions, stomach, and liver, and to spreading ulcers, but they are adverse to cicatrization. The bark of the tree, while tender, mixed with wax and resin, heals itch-scab in the course of twenty days: a decoction, also, is made of it for diseases of the testes. Used as a fumigation, it turns the hair black, and brings away the foetus. It is given in drink, also, for diseases of the kidneys, bladder, and thoracic organs; but it acts injuriously upon the head and nerves. The decoction of this bark has the effect, also, of arresting fluxes of the uterus and the bowels: the ashes of it are used with white wine for griping pains in the stomach, and form a very efficacious remedy for affections of the uterus.

Detailed table of contents

CHAP. 54. (6.)

REMEDIES DERIVED FROM THE BLOSSOMS, LEAVES, FRUIT, BRANCHES, BARK, JUICES, WOOD, ROOTS, AND ASHES OF VARIOUS KINDS OF TREES. SIX OBSERVATIONS UPON APPLES. TWENTY-TWO OBSERVATIONS UPON QUINCES. ONE OBSERVATION UPON STRUTHEA.

We next come to the medicinal properties of the various kinds of apples. The spring fruits of this nature are sour and unwholesome to the stomach, disturb the bowels, contract the bladder, and act injuriously upon the nerves; when cooked, however, they are of a more harmless nature. Quinces are more pleasant eating when cooked; still however, eaten raw, provided they are ripe, they are very useful for spitting of blood, dysentery, cholera, and *coeliac* affections; indeed, they are not of the same efficacy when cooked, as they then lose the astringent properties which belong to their juice. They are applied also to the breast in the burning attacks of fever, and, in spite of what has been stated above, they are occasionally boiled in rain-water for the various purposes before-mentioned. For pains in the stomach they are applied like a cerate, either raw or boiled. The down upon them heals carbuncles.

Boiled in wine, and applied with wax, they restore the hair, when it has been lost by alopecia. A conserve of raw quinces in honey relaxes the bowels; and they add very materially to the sweetness of the honey, and render it more wholesome to the stomach. Boiled quinces preserved in honey are beaten up with a decoction of rose-leaves, and are taken as food by some for the cure of affections of the stomach. The juice of raw quinces is very good, also, for the spleen, hardness of breathing, dropsy, affections of the *mamillæ*, *condylomata*, and varicose veins. The blossoms, either fresh or dried, are useful for inflammations of the eyes, spitting of blood, and irregularities of the catamenia. By beating them up with sweet wine, a soothing sirop is prepared, which, is very beneficial for *coeliac* affections and diseases of the liver: with a decoction of them a fomentation is made for procidence of the uterus and intestines.

From quinces an oil is also extracted, which we have spoken of under the name of “*melinum*:” in order to make it, the fruit must not have been grown in a damp soil; hence it is that the quinces which come from Sicily are so highly esteemed for the purpose; while, on the other hand, the *strutheum*, though of a kindred kind, is not so good.

A circle is traced round the root of this tree, and the root itself is then pulled up with the left hand, care being taken by the person who does so to state at the same moment the object for which it is so pulled up, and for whom. Worn as an amulet, this root is a cure for *scrofula*.

CHAP. 55.

THE SWEET APPLES CALLED MELIMELA: SIX OBSERVATIONS UPON THEM.
SOUR APPLES: FOUR OBSERVATIONS UPON THEM.

The apples known as “melimela,” and the other sweet apples, relax the stomach and bowels, but are productive of heat and thirst, though they do not act injuriously upon the nervous system. The orbiculata arrest diarrhœa and vomiting, and act as a diuretic. Wild apples resemble the sour apples of spring, and act astringently upon the bowels: indeed, for this purpose they should always be used before they are ripe.

Detailed table of contents

CHAP. 56.

CITRONS: FIVE OBSERVATIONS UPON THEM.

Citrons, either the pulp of them or the pips, are taken in wine as an antidote to poisons. A decoction of citrons, or the juice extracted from them, is used as a gargle to impart sweetness to the breath. The pips of this fruit are recommended for pregnant women to chew when affected with qualmsickness. Citrons are good, also, for a weak stomach, but it is not easy to eat them except with vinegar.

[Detailed table of contents](#)

CHAP. 57.

PUNIC APPLES OR POMEGRANATES: TWENTY-SIX REMEDIES.

It would be a mere loss of time to recapitulate the nine different varieties of the pomegranate. The sweet pomegranates, or, in other words, those known by the name of “apyrna,” are generally considered to be injurious to the stomach; they are productive, also, of flatulency, and are bad for the teeth and gums. The kind which closely resembles the last in flavour, and which we have spoken of as the “vinous” pomegranate, has very diminutive pips, and is thought to be somewhat more wholesome than the others. They have an astringent effect upon the stomach and bowels, provided they are taken in moderation, and not to satiety; but even these, or, indeed, any other kind, should never be given in fevers, as neither the substance nor the juice of the fruit acts otherwise than injuriously under those circumstances. They should, also, be equally abstained from in cases of vomiting and bilious evacuations.

In this fruit Nature has revealed to us a grape, and, so to say, not must, but a wine ready made, both grape and wine being enclosed in a tougher skin. The rind of the sour pomegranate is employed for many purposes. It is in very common use with curriers for tanning leather, from which circumstance it has received the name of “malicorium.” Medical men assure us that the rind is diuretic, and that, boiled with nut-galls in vinegar, it strengthens loose teeth in the sockets. It is prescribed also for pregnant women when suffering from qualmishness, the flavour of it quickening the foetus. A pomegranate is cut, and left to soak in rain-water for some three days; after which the infusion is given cold to persons suffering from cœliac affections and spitting of blood.

Detailed table of contents

CHAP. 58.

THE COMPOSITION CALLED STOMATICE: FOURTEEN REMEDIES.

With the sour pomegranate a medicament is made, which is known as “stomatice,” and is extremely good for affections of the mouth, nostrils, and ears, dimness of sight, films upon the eyes, diseases of the generative organs, corrosive sores called “nomæ,” and fleshy excrescences in ulcers; it is useful, also, as an antidote to the venom of the sea-hare. The following, is the method of making it: the rind is taken off the fruit, and the pips are pounded, after which the juice is boiled down to one-third, and then mixed with saffron, split alum, myrrh, and Attic honey, the proportions being half a pound of each.

Some persons have another way of making it: a number of sour pomegranates are pounded, after which the juice is boiled down in a new cauldron to the consistency of honey. This composition is used for various affections of the generative organs and fundament, and, indeed, all those diseases which are treated with lycium. It is employed, also, for the cure of purulent discharges from the ears, incipient defluxions of the eyes, and red spots upon the hands. Branches of the pomegranate have the effect of repelling the attacks of serpents. Pomegranate rind, boiled in wine and applied, is a cure for chilblains. A pomegranate, boiled down to onethird in three heminæ of wine, is a cure for griping pains in the bowels and for tape-worm. A pomegranate, put in anew earthen pot tightly covered and burnt in a furnace, and then pounded and taken in wine, arrests looseness of the bowels, and dispels griping pains in the stomach.

Detailed table of contents

CHAP. 59.

CYTINUS: EIGHT REMEDIES.

The Greeks have given the name of cytinus to the first germs of this tree when it is just beginning to blossom. These germs have a singular property, which has been re- marked by many. If a person, after taking off everything that is fastened upon the body, his girdle, for instance, shoes, and even his ring, plucks one of them with two fingers of the left hand, the thumb, namely, and the fourth finger, and, after rubbing it gently round his eyes, puts it into his mouth and swallows it without letting it touch his teeth, he will experience, it is said, no malady of the eyes throughout all the year. These germs, dried and pounded, check the growth of fleshy excrescences; they are good also for the gums and teeth; and if the teeth are loose a decoction of the germs will strengthen them.

The young pomegranates themselves are beaten up and applied as a liniment to spreading or putrid sores; they are used also for inflammations of the eyes and intestines, and nearly all the purposes for which pomegranate-rind is used. They are remedial also for the stings of scorpions.

[Detailed table of contents](#)

CHAP. 60.

BALAUSTIUM: TWELVE REMEDIES.

We cannot sufficiently admire the care and diligence displayed by the ancients, who, in their enquiries into every subject, have left nothing untried. Within the cytinus, before the pomegranate itself makes its appearance, there are dimi- nutive flowers, the name given to which, as already stated, is “balaustum.” These blossoms, even, have not escaped their enquiries; it having been ascertained by them that they are an excellent remedy for stings inflicted by the scorpion. Taken in drink, they arrest the catamenia, and are curative of ulcers of the mouth, tonsillary glands, and uvula, as also of spitting of blood, derangement of the stomach and bowels, diseases of the generative organs, and running sores in all parts of the body.

The ancients also dried these blossoms, to try their efficacy in that state, and made the discovery that, pulverized, they cure patients suffering from dysentery when at the very point of death even, and that they arrest looseness of the bowels. They have not disdained, too, to make trial of the pips of the pomegranate: parched and then pounded, these pips are good for the stomach, sprinkled in the food or drink. To arrest looseness of the bowels, they are taken in rain-water. A decoction of the juices of the root, in doses of one victoriatum, exterminates tape-worm; and the root itself, boiled down in water to a thick consistency, is employed for the same purposes as lycium.

Detailed table of contents

CHAP. 61.

THE WILD POMEGRANATE.

There is a tree, also, which is called the wild pomegranate, on account of its strong resemblance to the cultivated pomegranate. The roots of it have a red bark, which taken in wine in doses of one denarius, promotes sleep. The seed of it taken in drink is curative of dropsy. Gnats are kept at a distance by the smoke of burnt pomegranate rind.

Detailed table of contents

CHAP. 62. (7.)

PEARS: TWELVE OBSERVATIONS UPON THEM.

All kinds of pears, as an aliment, are indigestible, to persons in robust health, even; but to invalids they are forbidden as rigidly as wine. Boiled, however, they are re- markably agreeable and wholesome, those of Crustumium in particular. All kinds of pears, too, boiled with honey, are wholesome to the stomach. Cataplasms of a resolvent nature are made with pears, and a decoction of them is used to disperse indurations. They are efficacious, also, in cases of poisoning by mushrooms and fungi, as much by reason of their heaviness, as by the neutralizing effects of their juice.

The wild pear ripens but very slowly. Cut in slices and hung in the air to dry, it arrests looseness of the bowels, an effect which is equally produced by a decoction of it taken in drink; in which case the leaves also are boiled up together with the fruit. The ashes of pear-tree wood are even more efficacious as an antidote to the poison of fungi.

A load of apples or pears, however small, is singularly fatiguing to beasts of burden; the best plan to counteract this, they say, is to give the animals some to eat, or at least to shew them the fruit before starting.

Detailed table of contents

CHAP. 63.

FIGS: ONE HUNDRED AND ELEVEN OBSERVATIONS UPON THEM.

The milky juice of the fig-tree possesses kindred properties with vinegar; hence it is, that, like rennet, it curdles milk. This juice is collected before the fruit ripens, and dried in the shade; being used with yolk of egg as a liniment, or else in drink, with amylum, to bring ulcers to a head and break them, and for the purposes of an emmenagogue. With meal of fenugreek and vinegar, it is applied topically for gout; it acts also as a depilatory, heals eruptions of the eyelids, lichens and itch-scabs, and relaxes the bowels. The milk of the fig-tree is naturally curative of the stings of hornets, wasps, and similar insects, and is remarkably useful for wounds inflicted by scorpions. Mixed with axle-grease it removes warts. With the leaves and figs still green an application is made for scrofulous and other sores of a nature which requires emollients or resolvents. The leaves, too, used by themselves, are productive of a similar effect. In addition to this, they are employed for other purposes, as a friction for lichens, for example, for alopecia, and other diseases which require caustic applications. The young shoots of the branches are used as an application to the skin in cases of bites inflicted by dogs. With honey they are applied to the ulcers known as honeycomb ulcers; mixed with the leaves of wild poppies they extract splinters of bones; and the leaves beaten up in vinegar are a cure for bites inflicted by dogs. The young white shoots of the black fig are applied topically, with wax, to boils, and bites inflicted by the shrew-mouse: and the ashes of their leaves are used for the cure of gangrenes and the reduction of fleshy excrescences.

Ripe figs are diuretic and laxative; they promote the perspiration, and bring out pimples; hence it is that they are unwholesome in autumn, the perspirations which they excite being always attended with shivering. They are injurious also to the stomach, though for a short time only; and it is generally thought that they spoil the voice. The figs which are the last to ripen are more wholesome than the first, but those which are drugged for the purpose of ripening them are never wholesome. This fruit invigorates the young, and improves the health of the aged and retards the formation of wrinkles; it allays thirst, and is of a cooling nature, for which reason it should never be declined in those fevers of an astringent tendency which are known as "stegnæ."

Dried figs are injurious to the stomach, but are beneficial in a marvellous degree to the throat and fauces. They are of a warming nature, are productive of thirst, and relax the bowels, but are unwholesome in stomachic complaints and fluxes of the bowels. In all cases they are beneficial for the bladder, hardness of breathing, and asthma, as also for diseases of the liver, kidneys, and spleen. They are nourishing and invigorating, for which reason, the athletes in

former times used them as food: Pythagoras, the gymnast, being the first who introduced among them a flesh diet. Figs are extremely useful for patients recovering from a long illness, and for persons suffering from epilepsy or dropsy. They are applied topically also in all cases where sores require to be brought to a head, or dispersed; and they are still more efficacious when mixed with lime or nitre. Boiled with hyssop they act as a purgative on the pectoral organs, carry off the phlegm, and cure inveterate coughs: boiled with wine they heal maladies of the fundament, and tumours of the jaws. A decoction of them is applied also to boils, inflamed tumours, and imposthumes of the parotid glands. This decoction, too, is found very useful as a fomentation for disorders incident to females.

Boiled with fenugreek, figs are very useful in cases of pleurisy and peripneumony. A decoction of them with rue is good for griping pains in the bowels; in combination with verdigris, they are used for ulcers of the legs and imposthumes of the parotid glands; with pomegranates, for hang-nails; and with wax, for burns and chilblains. Boiled in wine, with wormwood and barley-meal, they are employed for dropsy. Eaten with nitre, they relax the bowels; and beaten up with salt they are applied to stings inflicted by scorpions. Boiled in wine, and applied topically, they bring carbuncles to a head. In cases of carcinoma, unattended with ulceration, it is a singularly good plan to apply to the part the pulpiest fig that can be procured; the same, too, with phagedænic sores.

As to the ashes of the fig, those of no tree known are of a more acrid character, being of a detergent and astringent nature, and tending to make new flesh and to promote the cicatrization of wounds. They are also taken in drink, for the purpose of dissolving coagulated blood, as also for bruises, falls with violence, ruptures, convulsions * * * * in one cyathus respectively of water and oil. They are administered also for tetanus and spasms, and are used either in a potion, or as an injection for cœliac affections and dysentery. Employed as a liniment with oil, they have a warming effect; and kneaded into a paste with wax and rose-oil, they heal burns, leaving the slightest scar only. Applied in oil, as a liniment, they are a cure for weakness of sight, and are used as a dentifrice in diseases of the teeth.

It is said, too, that if a patient draws downward a branch of a fig-tree, and turns up his head and bites off some knot or other of it, without being seen by any one, and then wears it in a leather bag suspended by a string from his neck, it is a certain cure for scrofulous sores and imposthumes of the parotid glands. The bark of this tree, beaten up with oil, cures ulcerations of the abdomen. Green figs, applied raw, with the addition of nitre and meal, remove warts and wens.

The ashes of the suckers which spring from the roots are used as a substitute for spodium. Burnt over a second time and incorporated with white lead, they are divided into cakes which are used for the cure of ulcerations of

the eyes and eruptions.

Detailed table of contents

CHAP. 64.

THE WILD FIG: FORTY-TWO OBSERVATIONS UPON IT.

The wild fig, again, is even more efficacious in its properties than the cultivated one. It has not so large a proportion of milky juice as the other: a slip of it put into milk has the effect of curdling it and turning it into cheese. This juice, collected and indurated by being subjected to pressure, imparts a fine flavour to meat, being steeped in vinegar for the purpose, and then rubbed upon it. It is used also as an ingredient in blisters, and taken internally it relaxes the bowels. Used with amyllum, it opens the passages of the uterus, and combined with the yolk of an egg it acts as an emmenagogue. Mixed with meal of fenugreek it is applied topically for gout, and is used for the dispersion of leprous sores, itch-scabs, lichens, and freckles: it is an antidote also to the stings of venomous animals, and to the bites of dogs. Applied to the teeth in wool, or introduced into the cavity of a carious tooth, this juice cures tooth-ache. The young shoots and the leaves, mixed with meal of fitches, act as an antidote to the poison of marine animals, wine being added to the preparation. In boiling beef a great saving of fire-wood may be effected, by putting some of these shoots in the pot.

The figs in a green state, applied topically, soften and disperse scrofulous sores and all kinds of gatherings, and the leaves, to a certain extent, have a similar effect. The softer leaves are applied with vinegar for the cure of running ulcers, epinyctis, and scaly eruptions. With the leaves, mixed with honey, honeycomb ulcers are treated, and wounds inflicted by dogs; the leaves are applied, too, fresh, with wine, to phagedænic sores. In combination with poppy-leaves, they extract splintered bones. Wild figs, in a green state, employed as a fumigation, dispel flatulency; and an infusion of them, used as a potion, combats the deleterious effects of bullocks' blood, white-lead, and coagulated milk, taken internally. Boiled in water, and employed as a cataplasm, they cure imposthumes of the parotid glands. The shoots, or the green figs, gathered as young as possible, are taken in wine for stings inflicted by scorpions. The milky juice is also poured into the wound, and the leaves are applied to it: the bite of the shrew-mouse is treated in a similar manner. The ashes of the young branches are curative of relaxations of the uvula; and the ashes of the tree itself, mixed with honey, have the effect of healing chaps. A decoction of the root, boiled in wine, is good for tooth-ache. The winter wild fig, boiled in vinegar and pounded, is a cure for impetigo: the branches are first barked for the purpose and then scraped; these scrapings, which are as fine as sawdust, being applied topically to the parts affected.

There is also one medicinal property of a marvellous nature attributed to the wild fig: if a youth who has not arrived at puberty breaks off a branch, and then with his teeth tears off the bark swelling with the sap, the pith of this

branch, we are assured, attached as an amulet to the person before sunrise, will prevent the formation of scrofulous sores. A branch of this tree, attached to the neck of a bull, however furious, exercises such a marvellous effect upon him as to restrain his ferocity, and render him quite immoveable.

Detailed table of contents

CHAP. 65.

THE HERB ERINEON: THREE REMEDIES.

It will be as well to speak here, in consequence of the similarity of name, of the herb which is known to the Greeks as the “erineon.” This plant is a palm in height, and has mostly five small stems: in appearance it resembles ocimum, and bears a white flower, with a small, black, seed. Beaten up with Attic honey, it is a cure for defluxions of the eyes. In whatever way it is gathered, it yields a considerable abundance of sweet, milky, juice. With the addition of a little nitre, this plant is extremely useful for pains in the ears. The leaves of it have the property of neutralizing poisons.

[Detailed table of contents](#)

CHAP. 66.

PLUMS: FOUR OBSERVATIONS UPON THEM.

The leaves of the plum, boiled in wine, are useful for the tonsillary glands, the gums, and the uvula, the mouth being rinsed with the decoction every now and then. As for the fruit itself, it is relaxing to the bowels; but it is not very wholesome to the stomach, though its bad effects are little more than momentary.

[Detailed table of contents](#)

CHAP. 67.

PEACHES: TWO REMEDIES.

Peaches, again, are more wholesome than plums; and the same is the case with the juice of the fruit, extracted, and taken in either wine or vinegar. Indeed, what known fruit is there that is more wholesome as an aliment than this? There is none, in fact, that has a less powerful smell, or a greater abundance of juice, though it has a tendency to create thirst. The leaves of it, beaten up and applied topically, arrest hæmorrhage: the kernels, mixed with oil and vinegar, are used as a liniment for head-ache.

[Detailed table of contents](#)

CHAP. 68.

WILD PLUMS: TWO REMEDIES.

The fruit of the wild plum, or the bark of the root, boiled down to one-third in one hemina of astringent wine, arrests looseness of the bowels and griping pains in the stomach: the proper dose of the decoction is one cyathus.

[Detailed table of contents](#)

CHAP. 69.

THE LICHEN ON PLUM-TREES: TWO REMEDIES.

Upon the bark of the wild and cultivated plums we find an excrescence growing, known to the Greeks by the name of “lichen:” it is remarkably good for chaps and condylomatous swellings.

Detailed table of contents

CHAP. 70.

MULBERRIES: THIRTY-NINE REMEDIES.

In Egypt and in the Isle of Cyprus there are, as already stated, mulberry-trees of a peculiar kind, being of a nature that is truly marvellous; for, if the outer bark is peeled off, they emit a great abundance of juice; but if a deeper incision is made, they are found to be quite dry. This juice is an antidote to the venom of serpents, is good for dysentery, disperses inflamed tumours and all kinds of gatherings, heals wounds, and allays both head-ache and ear-ache: it is taken in drink for affections of the spleen, and is used as a liniment for the same purpose, as also for fits of shivering. This juice, however, very soon breeds worms.

Among ourselves, too, the juice which exudes from the mulberry-tree is employed for an equal number of purposes: taken in wine, it neutralizes the noxious effects of aconite and the venom of spiders, relaxes the bowels, and expels tapeworm and other animals which breed in the intestines; the bark of the tree, pounded, has also a similar effect. The leaves, boiled in rain-water with the bark of the black fig and the vine, are used for dyeing the hair.

The juice of the fruit has a laxative effect immediately upon the bowels, though the fruit itself, for the moment, acts beneficially upon the stomach, being of a refreshing nature, but productive of thirst. If no other food is taken upon them, mulberries are of a swelling tendency. The juice of unripe mulberries acts astringently upon the bowels. The marvels which are presented by this tree, and of which we have made some mention when describing it, would almost appear to belong to a creature gifted with animation.

Detailed table of contents

CHAP. 71.

THE MEDICAMENT CALLED STOMATICE, ARTERIACE, OR PANCHRESTOS. FOUR REMEDIES.

From the fruit of the mulberry a medicament is prepared, called “panchrestos,” “stomatrice,” or “arteriace:” the following is the method employed. Three sextarii of the juice are reduced, at a slow heat, to the consistency of honey; two denarii of dried omphacium or one of myrrh, with one denarius of saffron, are then added, the whole being beaten up together and mixed with the decoction. There is no medicament known that is more soothing than this, for affections of the mouth, the trachea, the uvula, and the stomach. There is also another mode of preparing it: two sextarii of mulberry juice and one of Attic honey are boiled down in the manner above stated.

There are some other marvellous properties, also, which are mentioned in reference to this tree. When the tree is in bud, and before the appearance of the leaves, the germs of the fruit must be gathered with the left hand — the Greeks give them the name of “ricini.” These germs, worn as an amulet before they have touched the ground, have the effect of arresting hæmorrhage, whether proceeding from a wound, from the mouth, from the nostrils, or from piles; for which purposes they are, accordingly, put away and kept. Similar virtues are attributed to a branch just beginning to bear, broken off at full moon, provided also it has not touched the ground: this branch, it is said, attached to the arm, is peculiarly efficacious for the suppression of the catamenia when in excess. The same effect is produced, it is said, when the woman herself pulls it off, whatever time it may happen to be, care being taken not to let it touch the ground, and to wear it attached to the body. The leaves of the mulberry-tree beaten up fresh, or a decoction of them dried, are applied topically for stings inflicted by serpents: an infusion of them, taken in drink, is equally efficacious for that purpose. The juice extracted from the bark of the root, taken in wine or oxycrate, counteracts the venom of the scorpion.

We must also give some account of the method of preparing this medicament employed by the ancients: extracting the juice from the fruit, both ripe and unripe, they mixed it together, and then boiled it down in a copper vessel to the consistency of honey. Some persons were in the habit of adding myrrh and cypress, and then left it to harden in the sun, mixing it with a spatula three times a-day. Such was their receipt for the stomatrice, which was also employed by them to promote the cicatrization of wounds. There was another method, also, of dealing with the juice of this fruit: extracting the juice, they used the dried fruit with various articles of food, as tending to heighten the flavour; and they were in the habit of employing it medicinally for corroding ulcers, pituitous expectorations, and all cases in which astringents were required for the viscera. They used it also for the purpose of cleaning the teeth. A third mode of employing the juices of this tree is to boil

down the leaves and root, the decoction being used, with oil, as a liniment for the cure of burns. The leaves are also applied by themselves for the same purpose.

An incision made in the root at harvest-time, supplies a juice that is extremely useful for tooth-ache, gatherings, and suppurations; it acts, also, as a purgative upon the bowels. Mulberry-leaves, macerated in urine, remove the hair from hides.

Detailed table of contents

CHAP. 72.

CHERRIES: FIVE OBSERVATIONS UPON THEM.

Cherries are relaxing to the bowels and unwholesome to the stomach; in a dried state, however, they are astringent and diuretic. I find it stated by some authors, that if cherries are taken early in the morning covered with dew, the kernels being eaten with them, the bowels will be so strongly acted upon as to effect a cure for gout in the feet.

Detailed table of contents

CHAP. 73.

MEDLARS: TWO REMEDIES. SORBS: TWO REMEDIES.

Medlars, the setania excepted, which has pretty nearly the same properties as the apple, act astringently upon the stomach and arrest looseness of the bowels. The same is the case, too, with dried sorbs; but when eaten fresh, they are beneficial to the stomach, and are good for fluxes of the bowels.

[Detailed table of contents](#)

CHAP. 74. (8.)

PINE-NUTS: THIRTEEN REMEDIES.

Pine-nuts, with the resin in them, are slightly bruised, and then boiled down in water to one-half; the proportion of water being one sextarius to each nut. This decoction, taken in doses of two cyathi, is used for the cure of spitting of blood. The bark of the tree, boiled in wine, is given for griping pains in the bowels. The kernels of the pine-nut allay thirst, and assuage acridities and gnawing pains in the stomach; they tend also to neutralize vicious humours in that region, recruit the strength, and are salutary to the kidneys and the bladder. They would seem, however, to exercise an irritating effect upon the fauces, and to increase cough. Taken in water, wine, raisin wine, or a decoction of dates, they carry off bile. For gnawing pains in the stomach of extreme violence, they are mixed with cucumber-seed and juice of purslain; they are employed, too, in a similar manner for ulcerations of the bladder and kidneys, having a diuretic effect.

[Detailed table of contents](#)

CHAP. 75.

ALMONDS: TWENTY-NINE REMEDIES.

A decoction of the root of the bitter almond clears the complexion, and gives the face a brighter colour. Bitter almonds are provocative of sleep, and sharpen the appetite; they act, also, as a diuretic and as an emmenagogue. They are used topically for head-ache, when there is fever more particularly. Should the head-ache proceed from inebriation, they are applied with vinegar, rose-oil, and one sextarius of water. Used in combination with amyllum and mint, they arrest hæmorrhage. They are useful, also, for lethargy and epilepsy, and the head is anointed with them for the cure of epinyctis. In combination with wine, they heal putrid ulcers of an inveterate nature, and, with honey, bites inflicted by dogs. They are employed, also, for the cure of scaly eruptions of the face, the parts affected being fomented first.

Taken in water, or, as is often done, in an electuary, with resin of terebinth, they remove pains in the liver and kidneys; used with raisin wine, they are good for calculus and strangury. Bruised in hydromel, they are useful for cleansing the skin; and taken in an electuary with the addition of a small proportion of elelisphacus, they are good for diseases of the liver, cough, and colic, a piece about the size of a hazel-nut being taken in honey. It is said that if five bitter almonds are taken by a person before sitting down to drink, he will be proof against inebriation; and that foxes, if they eat bitter almonds, will be sure to die immediately, if they cannot find water to lap.

As to sweet almonds, their remedial properties are not so extensive; still, however, they are of a purgative nature, and are diuretic. Eaten fresh, they are difficult of digestion.

Detailed table of contents

CHAP. 76.

GREEK NUTS: ONE REMEDY.

Greek nuts, taken in vinegar with wormwood seed, are said to be a cure for jaundice. Used alone, they are employed topically for the treatment of diseases of the fundament, and condylomata in particular, as also cough and spitting of blood.

[Detailed table of contents](#)

CHAP. 77.

WALNUTS: TWENTY-FOUR REMEDIES. THE MITHRIDATIC ANTIDOTE.

Walnuts have received their name in Greek from being oppressive to the head; for, in fact, the emanations from the tree itself and the leaves penetrate to the brain. The kernels, also, have a similar effect when eaten, though not in so marked a degree. When fresh gathered, they are most agreeable eating; for when dry, they are more oleaginous, unwholesome to the stomach, difficult of digestion, productive of head-ache, and bad for cough, or for a person when about to take an emetic fasting: they are good in cases of tenesmus only, as they carry off the pituitous humours of the body. Eaten beforehand, they deaden the effects of poison, and, employed with rue and oil, they are a cure for quinsy. They act as a corrective, also, to onions, and modify their flavour. They are applied to inflammations of the ears, with a little honey, and with rue they are used for affections of the mamille, and for sprains. With onions, salt, and honey, they are applied to bites inflicted by dogs or human beings. Walnut-shells are used for cauterizing carious teeth; and with these shells, burnt and then beaten up in oil or wine, the heads of infants are anointed, they having a tendency to make the hair grow; hence they are used in a similar manner for alopecia also. These nuts, eaten in considerable numbers, act as an expellent upon tapeworm. Walnuts, when very old, are curative of gangrenous sores and carbuncles, of bruises also. Green walnut-shells are employed for the cure of lichens and dysentery, and the leaves are beaten up with vinegar as an application for earache.

After the defeat of that mighty monarch, Mithridates, Cneius Pompeius found in his private cabinet a recipe for an antidote in his own hand-writing; it was to the following effect: — Take two dried walnuts, two figs, and twenty leaves of rue; pound them all together, with the addition of a grain of salt; if a person takes this mixture fasting, he will be proof against all poisons for that day. Walnut kernels, chewed by a man fasting, and applied to the wound, effect an instantaneous cure, it is said, of bites inflicted by a mad dog.

[Detailed table of contents](#)

CHAP. 78.

HAZEL-NUTS: THREE OBSERVATIONS UPON THEM. PISTACHIO-NUTS: EIGHT OBSERVATIONS UPON THEM. CHESNUTS: FIVE OBSERVATIONS UPON THEM.

Hazel-nuts are productive of head-ache, and flatulency of the stomach; they contribute, however, to the increase of flesh more than would be imagined. Parched, they are remedial for catarrhs, and beaten up and taken with hydromel, they are good for an inveterate cough. Some persons add grains of pepper, and others take them in raisin wine.

Pistachio-nuts have the same properties, and are productive of the same effects, as pine-nuts; in addition to which, they are used as an antidote to the venom of serpents, eaten or taken in drink.

Chesnuts have a powerful effect in arresting fluxes of the stomach and intestines, are relaxing to the bowels, are beneficial in cases of spitting of blood, and have a tendency to make flesh.

Detailed table of contents

CHAP. 79.

CAROBS: FIVE OBSERVATIONS UPON THEM. THE CORNEL; ONE REMEDY. THE FRUIT OF THE ARBUTUS.

Fresh carobs are unwholesome to the stomach, and relaxing to the bowels; in a dried state, however, they are astringent, and are much more beneficial to the stomach; they are diuretic also. For pains in the stomach, persons boil three Syrian carobs with one sextarius of water, down to one-half, and drink the decoction.

The juices which exude from the branches of the cornel are received on a plate of red-hot iron without it touching the wood; the rust of which is applied for the cure of incipient lichens. The arbutus or unedo bears a fruit that is difficult of digestion, and injurious to the stomach.

[Detailed table of contents](#)

CHAP. 80.

THE LAUREL; SIXTY-NINE OBSERVATIONS UPON IT.

All parts of the laurel, both the leaves, bark, and berries, are of a warming nature; and a decoction of them, the leaves in particular, is very useful for affections of the bladder and uterus. The leaves, applied topically, neutralize the poison of wasps, bees, and hornets, as also that of serpents, the seps, dipsas, and viper, in particular. Boiled in oil, they promote the catamenia; and the more tender of the leaves beaten up with polenta, are used for inflammations of the eyes. with rue for inflammations of the testes, and with rose-oil, or oil of iris, for head-ache. Three leaves, chewed and swallowed for three days in succession, are a cure for cough, and beaten up with honey, for asthma. The bark of the root is dangerous to pregnant women; the root itself disperses calculi, and taken in doses of three oboli in aromatic wine, it acts beneficially on the liver. The leaves, taken in drink, act as an emetic; and the berries, pounded and applied as a pessary, or else taken in drink, promote menstruation. Two of the berries with the skin removed, taken in wine, are a cure for inveterate cough and hardness of breathing; if, however, this is accompanied with fever, they are given in water, or else in an electuary with raisin wine, or boiled in hydromel. Employed in a similar manner, they are good for phthisis, and for all defluxions of the chest, as they have the effect of detaching the phlegm and bringing it off.

For stings inflicted by scorpions, four laurel-berries are taken in wine. Applied with oil, they are a cure for epinictis, freckles, running sores, ulcers of the mouth, and scaly eruptions. The juice of the berries is curative of porrigo and phthiriasis; and for pains in the ears, or hardness of hearing, it is injected into those organs with old wine and oil of roses. All venomous creatures fly at the approach of persons who have been anointed with this juice: taken in drink, the juice of the small-leaved laurel in particular, it is good for stings inflicted by them. The berries, used with wine, neutralize the venom of serpents, scorpions, and spiders; they are applied also, topically, with oil and vinegar, in diseases of the spleen and liver, and with honey to gangrenous sores. In cases of lassitude and shivering fits, it is a very good plan to rub the body with juice of laurel-berries mixed with nitre. Some persons are of opinion that delivery is accelerated by taking laurel-root to the amount of one acetabulum, in water, and that, used fresh, it is better than dried. It is recommended by some authorities, to take ten of the berries in drink, for the sting of the scorpion; and in cases of relaxation of the uvula, to boil a quarter of a pound of the berries, or leaves, in three sextarii of water, down to one third, the decoction being used warm, as a gargle. For head-ache, also, it is recommended to bruise an uneven number of the berries in oil, the mixture being warmed for use.

The leaves of the Delphic laurel bruised and applied to the nostrils from time to time, are a preservative against contagion in pestilence, and more particularly if they are burnt. The oil of the Delphic laurel is employed in the preparation of cerates and the medicinal composition known as “acopum,” and is used for fits of shivering occasioned by cold, for the relaxation of the sinews, and for the cure of pains in the side and the cold attacks in fevers. Warmed in the rind of a pomegranate, it is applied topically for the cure of ear-ache. A decoction of the leaves boiled down in water to one third, used as a gargle, braces the uvula, and taken in drink allays pains in the bowels and intestines. The more tender leaves, bruised in wine and applied at night, are a cure for pimples and prurigo.

The other varieties of the laurel possess properties which are nearly analogous. The root of the laurel of Alexandria, or of Mount Ida, accelerates delivery, being administered in doses of three denarii to three cyathi of sweet wine; it acts also as an emmenagogue, and brings away the after-birth. Taken in drink in a similar manner, the wild laurel, known as “daphnoides” and by the other names which we have mentioned, is productive of beneficial effects. The leaves of it, either fresh or dried, taken in doses of three drachmæ, in hydromel with salt, act as a purgative upon the bowels. The wood, chewed, brings off phlegm, and the leaves act as an “emetic;” they are unwholesome, however, to the stomach. The berries, too, are sometimes taken, fifteen in number, as a purgative.

Detailed table of contents

CHAP. 81.

MYRTLE; SIXTY OBSERVATIONS UPON IT.

The white cultivated myrtle is employed for fewer medicinal purposes than the black one. The berries of it are good for spitting of blood, and taken in wine, they neutralize the poison of fungi. They impart an agreeable smell to the breath, even when eaten the day before; thus, for instance, in Menander we find the Synaristosæ eating them. They are taken also for dysentery, in doses of one denarius, in wine: and they are employed lukewarm, in wine, for the cure of obstinate ulcers on the extremities. Mixed with polenta, they are employed topically in ophthalmia, and for the cardiac disease they are applied to the left breast. For stings inflicted by scorpions, diseases of the bladder, head-ache, and fistulas of the eye before suppuration, they are similarly employed; and for tumours and pituitous eruptions, the kernels are first removed and the berries are then pounded in old wine. The juice of the berries acts astringently upon the bowels, and is diuretic: mixed with cerate it is applied topically to blisters, pituitous eruptions, and wounds inflicted by the phalangium; it imparts a black tint, also, to the hair.

The oil of this myrtle is of a more soothing nature than the juice, and the wine which is extracted from it, and which possesses the property of never inebriating, is even more so. This wine, used when old, acts astringently upon the stomach and bowels, cures griping pains in those regions, and dispels nausea.

The dried leaves, powdered and sprinkled upon the body, check profuse perspirations, in fever even; they are good, too, used as a fomentation, for cœliac affections, procidence of the uterus, diseases of the fundament, running ulcers, erysipelas, loss of the hair, scaly and other eruptions, and burns. This powder is used as an ingredient, also, in the plasters known as “liparæ;” and for the same reason the oil of the leaves is used for a similar purpose, being extremely efficacious as an application to the humid parts of the body, the mouth and the uterus, for example.

The leaves themselves, beaten up with wine, neutralize the bad effects of fungi; and they are employed, in combination with wax, for diseases of the joints, and gatherings. A decoction of them, in wine, is taken for dysentery and dropsy. Dried and reduced to powder, they are sprinkled upon ulcers and hæmorrhages. They are useful, also, for the removal of freckles, and for the cure of hang-nails, whitlows, condylo- mata, affections of the testes, and sordid ulcers. In combination with cerate, they are used for burns.

For purulent discharges from the ears, the ashes of the leaves are employed, as well as the juice and the decoction: the ashes are also used in the composition of antidotes. For a similar purpose the blossoms are stripped from off the young branches, which are burnt in a furnace, and then pounded

in wine. The ashes of the leaves, too, are used for the cure of burns. To prevent ulcerations from causing swellings in the inguinal glands, it will suffice for the patient to carry a sprig of myrtle about him which has never touched the ground or any implement of iron.

Detailed table of contents

CHAP. 82.

MYRTIDANUM: THIRTEEN REMEDIES.

We have already described the manner in which myrtidanum is made. Applied in a pessary, or as a fomentation or liniment, it is good for affections of the uterus, being much more efficacious than the bark of the tree, or the leaves and seed. There is a juice also extracted from the more tender leaves, which are pounded in a mortar for the purpose, astringent wine, or, according to one method, rain-water, being poured upon them a little at a time. This extract is used for the cure of ulcers of the mouth, the fundament, the uterus, and the abdomen. It is employed, also, for dyeing the hair black, the suppression of exudations at the arm-pits, the removal of freckles, and other purposes in which astringents are required.

Detailed table of contents

CHAP. 83.

THE WILD MYRTLE, OTHERWISE CALLED OXYMYRSINE, OR CHAMÆMYRSINE,
AND THE RUSCUS: SIX REMEDIES.

The wild myrtle, oxymyrsine, or chamæmyrsine, differs from the cultivated myrtle in the redness of its berries and its diminutive height. The root of it is held in high esteem; a decoction of it, in wine, is taken for pains in the kidneys and strangury, more particularly when the urine is thick and fetid. Pounded in wine, it is employed for the cure of jaundice, and as a purgative for the uterus. The same method is adopted, also, with the young shoots, which are sometimes roasted in hot ashes and eaten as a substitute for asparagus.

The berries, taken with wine, or oil and vinegar, break calculi of the bladder: beaten up with rose-oil and vinegar, they allay head-ache. Taken in drink, they are curative of jaundice. Castor calls the wild myrtle with prickly leaves, or oxymyrsine, from which brooms are made, by the name of “ruscus” — the medicinal properties of it are just the same.

Thus much, then, with reference to the medicinal properties of the cultivated trees; let us now pass on to the wild ones.

Summary. — Remedies, narratives, and observations, nine hundred and eighteen.

Roman Authors Quoted. — C. Valgius, Pompeius Linnæus, Sextius Niger who wrote in Greek, Julius Bassus who wrote in Greek, Antonius Castor, M. Varro, Cornelius Celsus, Fabianus.

Foreign Authors Quoted. — Theophrastus, Democritus, Orpheus, Pythagoras, Mago, Menander who wrote the “Biochresta,” Nicander, Homer, Hesiod, Musæus, Sophocles, Anaxilaüs.

Medical Authors Quoted. — Mnesitheus, Callimachus, Phantias the physician, Timaristus, Simus, Hippocrates, Chrysippus, Diocles, Ophelion, Heraclides Hicesius, Dionysius, Apollodorus of Citium, Apollodorus of Tarentum, Plistonicus, Medius, Dieuches, Cleophantus, Philistion, Asclepiades, Crateuas, Petronius Diodotus, Iollas, Erasistratus, Diagoras, Andreas, Mnesides, Epicharmus, Damion, Dalion, Sosimenes, Tlepolemus, Metrodorus, Solo, Lycus, Olympias of Thebes, Philinus, Petrichus, Micton, Glaucias, Xenocrates.

Detailed table of contents

BOOK XXIV. THE REMEDIES DERIVED FROM THE FOREST TREES.

Detailed table of contents

CHAP. 1. (1.)

THE ANTIPATHIES AND SYMPATHIES WHICH EXIST AMONG TREES AND PLANTS.

NOT even are the forests and the spots in which the aspect of Nature is most rugged, destitute of their peculiar remedies; for so universally has that divine parent of all things distributed her succours for the benefit of man, as to implant for hint medicinal virtues in the trees of the desert even, while at every step she presents us with most wonderful illustrations of those antipathies and sympathies which exist in the vegetable world.

Between the quercus and the olive there exists a hatred so inveterate, that transplanted, either of them, to a site previously occupied by the other, they will die. The quercus too, if planted near the walnut, will perish. There is a mortal feud existing also between the cabbage and the vine; and the cabbage itself, so shunned as it is by the vine, will wither immediately if planted in the vicinity of cyclamen or of origanum. We find it asserted even, that aged trees fit to be felled, are cut with all the greater difficulty, and dry all the more rapidly, if touched by the hand of man before the axe is applied: it is a common belief, too, that when their load consists of fruit, beasts of burden are immediately sensible of it, and will instantly begin to sweat, however trifling it may be, unless the fruit is duly shown to them before starting. Fennel-giant, as a fodder, is extremely grateful to the ass, and yet to other beasts of burden it is a deadly poison: hence it is that the ass is consecrated to Father Liber, to which deity the fennel is also sacred.

Inanimate objects again, even of the most insignificant character, have their own peculiar antipathies. Cooks disengage meat of the brine, when it has been too highly salted, by the agency of fine meal and the inner bark of the lindentree. Salt again, tends to neutralize the sickly flavour of food when over-sweet. The taste of water, when nitrous or bitter, is modified by the addition of polenta, so much so indeed, as to be rendered potable in a couple of hours: it is for a similar reason, too, that a layer of polenta is put in our linen winestrainers. A similar property is possessed also by the chalk of Rhodes, and the argilla of our own country.

Equal affinities exist as well; pitch, for instance, is extracted by the agency of oil, both of them being of an unctuous nature oil again, will incorporate only with lime, both of them having a natural antipathy to water. Gum is most easily removed with vinegar, and ink with water; in addition to which, there are numberless other instances of sympathy and antipathy which we shall be careful to mention in their appropriate places.

It is in tendencies of this description that the medical art first took its rise; though it was originally intended, no doubt, by Nature, that our only medicaments should be those which universally exist, are everywhere to be found, and are to be procured at no great outlay, the various substances, in

fact, from which we derive our sustenance. But at a later period the fraudulent disposition of mankind, combined with an ingenuity prompted by lucre, invented those various laboratories, in which each one of us is promised an extension of his life — that is, if he will pay for it. Compositions and mixtures of an inexplicable nature forthwith have their praises sung, and the productions of Arabia and India are held in unbounded admiration in the very midst of us. For some trifling sore or other, a medicament is prescribed from the shores of the Red Sea; while not a day passes but what the real remedies are to be found upon the tables of the very poorest man among us. But if the remedies for diseases were derived from our own gardens, if the plants or shrubs were employed which grow there, there would be no art, forsooth, that would rank lower than that of medicine.

Yes, avow it we must—the Roman people, in extending its empire, has lost sight of its ancient manners, and in that we have conquered we are the conquered: for now we obey the natives of foreign lands, who by the agency of a single art have even out-generalled our generals. More, however, on this topic hereafter.

Detailed table of contents

CHAP. 2. (2.)

THE LOTUS OF ITALY: SIX REMEDIES.

We have already spoken in their appropriate places of the herb called lotus, and of the plant of Egypt known by the same name and as the “tree of the Syrtes.” The berries of the lotus, which is known among us as the “Grecian bean,” act astringently upon the bowels; and the shavings of the wood, boiled in wine, are useful in cases of dysentery, excessive menstruation, vertigo, and epilepsy: they also prevent the hair from falling off. It is a marvellous thing — but there is no substance known that is more bitter than the shavings of this wood, or sweeter than the fruit. The sawdust also of the wood is boiled in myrtle-water, and then kneaded and divided into lozenges, which form a medicament for dysentery of remarkable utility, being taken in doses of one victoriatum, in three cyathi of water.

Detailed table of contents

CHAP. 3. (3.)

ACORNS: THIRTEEN REMEDTES.

Acorns, pounded with salted axle-grease, are curative of those indurations known as “cacoethe.” The acorn of the holm-oak, however, is the most powerful in its effects; ad(in all these trees the bark is still more efficacious, as well as the inner membrane which lies beneath it. A decoction of this last is good for cœliac affections; and it is applied topically in cases of dysentery, as well as the acorns, which are employed also for the treatment of stings inflicted by serpents, fluxes, and suppurations. The leaves, acorns, and bark, as well as a decoction prepared from them, are good as counter- poisons. A decoction of the bark, boiled in cows’ milk, is used topically for stings inflicted by serpents, and is administered in wine for dysentery. The holm-oak is possessed of similar properties.

Detailed table of contents

CHAP. 4. (4.)

TIE KERMES-BERRY OF THE HOLM-OAK: THREE: REMEDIES.

The scarlet berry of the holm-oak is applied to fresh wounds with vinegar; and in combination with water it is dropt into the eyes in cases of defluxion of those organs or of ecchymosis. There grows also in most parts of Attica, and in Asia, a berry of this description, which becomes transformed with great rapidity into a diminutive worm, owing to which circumstance the Greeks have given it the name of “scolecion:” it is held, however, in disesteem. The principal varieties of this berry have been previously described.

Detailed table of contents

CHAP. 5.

GALL-NUTS: TWENTY-THREE REMEDIES.

And no fewer are the varieties of the gall-nut which we have described: we have, for instance, the full-bodied gallnut, the perforated one, the white, the black, the large, the small, all of them possessed of similar properties; that, however, of Commagene is generally preferred. These substances remove fleshy excrescences on the body, and are serviceable for affections of the gums and uvula, and for ulcerations of the mouth. Burnt, and then quenched in wine, they are applied topically in cases of cœliac affections and dysentery, and with honey, to whitlows, hang-nails, malformed nails, running ulcers, condylomatous swellings, and ulcerations of the nature known as phagedænic. Adecoction of them in wine is used as an injection for the ears, and as a liniment for the eyes, and in combination with vinegar they are employed for eruptions and tumours.

The inner part of the gall, chewed, allays tooth-ache, and is good for excoriations between the thighs, and for burns. Taken unripe in vinegar, they reduce the volume of the spleen; and, burnt and then quenched in salt and vinegar, they are used as a fomentation for excessive menstruation and procidence of the uterus. All varieties of the gall-nut stain the hair black.

[Detailed table of contents](#)

CHAP. 6.

MISTLETOE: ELEVEN REMEDIES.

We have already stated that the best mistletoe is that which grows on the robur, and have described the manner in which it is prepared. Some persons, after bruising the berries, boil them in water, till nothing appears on the surface, while others, again, bite the berries with the teeth, and reject the skins. The best kind of viscus is that which has none of the outer skin in it, is extremely light, yellow without, and of a leek-green colour within. There is no substance more glutinous than this: it is of an emollient nature, disperses tumours, and acts as a desiccative upon scrofulous sores; combined with resin and wax, it heals inflamed swellings of every description. Some persons add galbanum as well, using equal proportions of each ingredient, and this preparation they employ also for the treatment of wounds.

The viscus of the mistletoe has the additional property also of rectifying malformed nails; but to effect this it must be taken off at the end of seven days, and the nails must be washed with a solution of nitre. Some persons have a sort of superstitious notion that the viscus will be all the more efficacious if the berries are gathered from the robur at new moon, and without the aid of iron. They have an impression too, that if it has not touched the ground, it will cure epilepsy, that it will promote conception in females if they make a practice of carrying it about them: the berries, chewed and applied to ulcers, are remarkably efficacious for their cure, it is said.

Detailed table of contents

CHAP. 7.

THE EXCRESCENCES WHICH GROW ON THE ROBUR: ONE REMEDY. THE
CHRRUS: EIGHT REMEDIES.

The round excrescences which grow on the robur * * * and mixed with bear's grease, are remedial in cases of loss of the hair by alopecia.

The leaves, bark, and acorns of the cerrus act as a desiccative upon gatherings and suppurations, and arrest fluxes. A decoction of them, used as a fomentation, strengthens such parts of the body as are paralyzed; and it is a very good plan to employ it as a sitting-bath, for its desiccative or astringent effects upon the lower extremities. The root of this tree neutralizes the venom of the scorpion.

Detailed table of contents

CHAP. 8.

THE-CORK TREE: TWO REMEDIES.

The bark of the cork-tree, pulverized and taken in warm water, arrests hæmorrhage at the mouth and nostrils; and the ashes of it, taken in warm wine, are highly extolled as a cure for spitting of blood.

Detailed table of contents

CHAP. 9. (5.)

THE BEECUH: FOUR REMEDIES.

The leaves of the beech are chewed for affections of the lips and gums. A liniment is made of the ashes of beech- mast for urinary calculus, and, in combination with honey, for alopecia.

[Detailed table of contents](#)

CHAP. 10.

THE CYPRESS: TWENTY-THREE REMEDIES.

The leaves of the cypress are pounded and applied to wounds inflicted by serpents, and with polenta, to the head, in cases of sunstroke. They are used also for hernia, and an infusion of them is taken in drink. They are applied with wax to swellings of the testes, and mixed with vinegar they stain the hair black. Beaten up with twice the quantity of light bread, and then kneaded with Aminean wine, they are found very soothing for pains in the Feet and sinews.

The excrescences of this tree are taken in drink for the stings of serpents and for discharges of blood from the mouth they are used also as a topical application for gatherings. Fresh-gathered and beaten up with axle-grease and bean-meal, they are good for hernia; and an infusion of them is taken in drink for the same complaint. In combination with meal, they are applied topically to imposthumes of the parotid glands, and to scrofulous sores. From these excrescences, pounded along with the seed, a juice is extracted, which, mixed with oil, disperses films of the eyes. Taken in doses of one victoriatum, in wine, and applied at the same time in a pulpy, dried fig, the seeds of which have been removed, this juice cures maladies of the testes and disperses tumours: mixed with leaven, it heals scrofulous sores.

The root of the cypress, bruised with the leaves and taken in drink, is curative of diseases of the bladder, strangury, and the sting of the phalangium. The shavings of the wood, taken in drink, act as an emmenagogue, and neutralize the venom of the scorpion.

[Detailed table of contents](#)

CHAP. 11.

THE CEDAR: THIRTEEN REMEDIES.

The larger cedar, known as the “cedrelates,” produces a pitch called “cedria,” which is very useful for tooth-ache, it having the effect of breaking the teeth and extracting them, and so allaying the pain. We have already stated how the juices of cedar are extracted, so remarkably useful for seasoning books, were it not for the head-ache they produce. This extract from the cedar preserves the bodies of the dead uncorrupted for ages, but exercises a noxious effect upon the bodies of the living-singular that there should be such a diversity in its properties, taking away life from animated beings, and imparting a sort of life, as it were, to the dead! It injures clothing also and destroys animal life. It is for this reason that I cannot recommend it to be taken internally for the cure of quinzy and indigestion, though there are some who advise it: I should be greatly in dread too, to rinse the teeth with it, in combination with vinegar, for tooth-ache, or to use it as an injection for the ears in cases of hardness of hearing, or for worms in those organs. There is one very marvellous story told about it — if the male organs, they say, are rubbed with it just before the sexual congress, it will effectually prevent impregnation.

Still, however, I should not hesitate to employ it as a friction for phthiriasis or porrigo. It is strongly recommended also, in raisin wine, as an antidote to the poison of the sea- share, but I should be more ready to use it as a liniment for elephantiasis. Some authors have prescribed it as an ointment for foul ulcers and the fleshy excrescences which grow in them, as also for spots and films on the eyes; and have recommended it to be taken, in doses of one cyathus, for ulcerations of the lungs, and for tapeworm.

There is an oil extracted from this pitch, known as “pisselæpon,” the properties of which are of increased activity for all the purposes before-mentioned. It is a well-known fact that the saw-dust of cedar will put serpents to flight, and that a similar effect is produced by anointing the body with the berries bruised in oil.

[Detailed table of contents](#)

CHAP. 12.

CEDRIDES: TEN REMEDIES.

Cedrides, or in other words, the fruit of the cedar, is curative of coughs, acts as a diuretic, and arrests looseness of the bowels. It is good also for ruptures, convulsions, spasms, and strangury, and is employed, as a pessary, for affections of the uterus. It is used also to neutralize the venom of the sea-hare, and for the cure of the various affections above-mentioned, as also of gatherings and inflammations.

[Detailed table of contents](#)

CHAP. 13.

GALBANUM: TWENTY-THREE REMEDIES.

We have already given some description of galbanum: to be good, it should be neither too moist nor too dry, but just in the state which we have mentioned. It is taken by itself for inveterate coughs, asthma, ruptures, and convulsions; and it is employed externally for sciatica, pains in the sides, inflamed tumours, boils, denudations of the bones, scrofulous sores, nodes upon the joints, and tooth-ache. It is applied with honey also, to ulcerations of the head. In combination with oil of roses or with nard, it is used as an injection for suppurations of the ears; and the odour of it is useful for epilepsy, hysterical suffocations, and faintness at the stomach. Employed as a pessary or as a fumigation, it brings away the fœtus in cases of miscarriage; branches too of hellebore covered with it and laid beneath the patient, have a similar effect.

We have already stated that serpents are driven away by the fumes of burnt galbanum, and they will equally avoid persons whose body has been rubbed with it. It is curative also of the sting of the scorpion. In protracted deliveries, a piece of galbanum the size of a bean is given in one cyathus of wine: it has the effect also of reducing the uterus when displaced, and, taken with myrrh and wine, it brings away the dead fœtus. In combination with myrrh and wine too, it neutralizes poisons — those which come under the denomination of “toxica” in particular. The very touch of it, mixed with oil and spondylium, is sufficient to kill a serpent. It is generally thought to be productive of strangury.

[Detailed table of contents](#)

CHAP. 14. (6.)

HAMMONIACUM: TWENTY-FOUR REMEDIES.

Of a similar nature to galbanum is hammoniacum, a tear-like gum, the qualities of which are tested in manner already stated. It is of an emollient, warming, resolvent, and dispellent nature. Employed as an ingredient in eye-salves, it improves the sight. It disperses prurigo, effaces the marks of sores, removes spots in the eyes, and allays tooth-ache, more particularly when burnt. It is very useful too, taken in drink, for hardness of breathing, pleurisy, affections of the lungs, diseases of the bladder, bloody urine, maladies of the spleen, and sciatica: employed in a similar manner, it acts as a purgative upon the bowels. Boiled with an equal proportion of pitch or wax, and with oil of roses, it is good for diseases of the joints, and for gout. Employed with honey it ripens hard tumours, extracts corns, and has an emollient effect upon indurations. In combination with vinegar and Cyprian wax, or oil of roses, it is extremely efficacious as a liniment for affections of the spleen. In cases of extreme lassitude, it is an excellent plan to use it as a friction, with vinegar and oil, and a little nitre.

[Detailed table of contents](#)

CHAP. 15.

STORAX: TEN REMEDIES.

In speaking too of the exotic trees, we have made mention of the properties of storax. In addition to those which we have already mentioned, it ought to be very unctuous, without alloy, and to break to pieces in whitish fragments. This substance is curative of cough, affections of the fauces, diseases of the chest, and obstructions or indurations of the uterus. Taken in drink, or employed as a pessary, it acts as an emmenagogue; it has a laxative effect also upon the bowels. I find it stated that, taken in moderate doses, storax dispels melancholy; but that when employed in large quantities, it promotes it. Used as an injection it is good for singings in the ears, and employed as a friction, for scrofulous swellings and nodes of the sinews. It neutralizes poisons of a cold nature, and consequently, hemlock.

Detailed table of contents

CHAP. 16.

SPONDYLIUM: SEVENTEEN REMEDIES.

At the same time we have also spoken of spondylium; an infusion of which is poured upon the head in cases of phrenitis and lethargy, and of head-ache of long standing. Combined with old oil, it is taken in drink for affections of the liver, jaundice, epilepsy, hardness of breathing, and hysterical suffocations, maladies for which it is equally serviceable in the shape of a fumigation. It relaxes the bowels, and with rue it is applied to ulcers of a serpiginous nature. The juice which is extracted from the blossom is a most useful injection for suppurations of the ears; but the moment it is extracted it should be covered up, as flies and other insects of a similar nature are remarkably fond of it. Scrapings of the root, introduced into the interior of fistulas, have a caustic effect upon their callosities; and they are sometimes used, in combination with the juice, as an injection for the ears. The root itself also is prescribed for jaundice, and for diseases of the liver and uterus. If the head is rubbed with the juice, it will make the hair curl.

[Detailed table of contents](#)

CHAP. 17.

SPHAGNOS, SPHACOS, OR BRYON: FIVE REMEDIES.

Sphagnos, sphacos, or bryon, grows, as we have already stated, in Gaul. A decoction of it, employed as a sitting-bath, is useful for affections of the uterus: mixed with nasturtium, and beaten up in salt water, it is good for the knees and for swellings in the thighs. Taken in drink with wine and dried resin, it acts very powerfully as a diuretic. Pounded in wine with juniper berries, and taken in drink, it draws off the water in dropsy.

[Detailed table of contents](#)

CHAP. 18.

THE TEREBINTH: SIX REMEDIES.

The leaves and root of the terebinth are used as applications for gatherings; and a decoction of them is strengthening to the stomach. The seed of it is taken in wine for head-ache and strangury: it is slightly laxative to the bowels, and acts as an aphrodisiac.

Detailed table of contents

CHAP. 19.

THE PITCH-TREE AND THE LARCH: EIGHT REMEDIES.

The leaves of the pitch-tree and the larch, beaten up and boiled in vinegar, are good for tooth-ache. The ashes of the bark are used for excoriations and burns. Taken in drink this substance arrests diarrhœa, and acts as a diuretic; and used as a fumigation, it reduces the uterus when displaced. The leaves of the pitch-tree are particularly good for the liver, taken in doses of one drachma in hydromel.

It is a well-known fact that forests planted solely with trees from which pitch and resin are extracted, are remarkably beneficial for patients suffering from phthisis, or who are unable to recover their strength after a long illness: indeed it is said, that in such cases to breathe the air of localities thus planted, is more beneficial even than to take a voyage to Egypt. or to go on a summer's journey to the mountains to drink the milk there, impregnated with the perfumes of plants.

Detailed table of contents

CHAP. 20.

THE CHAMÆPITYS: TEN REMEDIES.

The chamæpitys, called in Latin “abiga,” because it promotes abortion, and known to some as “incense of the earth,” has branches a cubit in length, and the odour and blossoms of the pine. Another variety of it, which is somewhat shorter, has all the appearance of being bent down-wards; and there is a third, which, though it has a similar smell, and consequently the same name, is altogether smaller, with a stem the thickness of one’s finger, and a diminutive, rough, pale leaf: it is found growing in rocky localities. All these varieties are in reality herbaceous productions; but in consequence of the resemblance of the name, I have thought it as well not to defer the consideration of them.

These plants are good for stings inflicted by scorpions, and are useful as an application, mixed with dates or quinces, for maladies of the liver: a decoction of them with barley-meal is used for the kidneys and the bladder. A decoction of them in water is used also for jaundice and for strangury. The kind last mentioned, in combination with honey, is good for wounds inflicted by serpents, and a pessary is made of it, with honey, as a detergent for the uterus. Taken in drink it brings away coagulated blood, and rubbed upon the body it acts as a sudorific: it is particularly useful also for the kidneys. Pills of a purgative nature are made of it for dropsy, with figs. Taken in wine, in doses of one victoriatum, it dispels lumbago, and cures coughs that are not of an inveterate description. A decoction of it in vinegar, taken in drink, will instantaneously bring away the dead fœtus, it is said.

[Detailed table of contents](#)

CHAP. 21.

THE PITYUSA: SIX REMEDIES.

For a similar reason, too, we shall accord the same distinction to the pityusa, a plant which some persons reckon among the varieties of the tithymalus. It is a shrub, re-sembling the pitch-tree in appearance, and with a diminutive purple blossom. A decoction of the root, taken in doses of one hemina, carries off the bilious and pituitous secretions by stool, and a spoonful of the seed, used as a suppository, has a similar effect. A decoction of the leaves in vinegar removes scaly eruptions of the skin; and in combination with boiled rue, it effects the cure of diseases of the mamillæ, gripings in the bowels, wounds inflicted by serpents, and incipient gatherings of most kinds.

Detailed table of contents

CHAP. 22.

RESINS: TWENTY-TWO REMEDIES.

In treating, first of wines, and then of trees, we have stated that resin is the produce of the trees above-mentioned, and have described the several varieties of it, and the countries in which they are respectively produced. There are two principal kinds of resin, the dry and the liquid. The dry resins are extracted from the pine and the pitch-tree, the liquid from the terebinth, the larch, the lentisk, and the cypress; these last producing it in the province of Asia and in Syria. It is an error to suppose that the resin of the pitch-tree is the same as that of the larch; for the pitch-tree yields an unctuous resin, and of the same consistency as frankincense, while that of the larch is thin, like honey in colour, and of a powerful odour. It is but very rarely that medical men make use of liquid resin, and when they do, it is mostly that produced by the larch, which is administered in an egg for cough and ulcerations of the viscera. The resin of the pine, too, is far from extensively used, and that of the other kinds is always boiled before use: on the various methods of boiling it, we have enlarged at sufficient length already.

As to the produce of the various trees, the resin of the terebinth is held in high esteem, as being the most odoriferous and the lightest, the kinds which come from Cyprus and Syria being looked upon as the best. Both these kinds are the colour of Attic honey; but that of Cyprus has more body, and dries with greater rapidity. In the dry resins the qualities requisite are whiteness, purity, and transparency: but whatever the kind, the produce of mountainous districts is always preferred to that of champaign countries, and that of a north-eastern aspect to that of any other quarter. Resins are dissolved in oil as a liniment and emollient cataplasm for wounds; but when they are used as a potion, bitter almonds are also employed. The curative properties of resins consist in their tendency to close wounds, to act as a detergent upon gatherings and so disperse them, and to cure affections of the chest.

The resin of the terebinth * * * it is used too, warmed, as a liniment for pains in the limbs, the application being removed after the patient has taken a walk in the sun. Among slave-dealers too, there is a practice of rubbing the bodies of the slaves with it, which is done with the greatest care, as a corrective for an emaciated appearance; the resin having the property of relaxing the skin upon all parts of the body, and rendering it more capable of being plumped out by food.

Next after the resin of the terebinth comes that of the lentisk; it possesses astringent properties, and is the most powerful diuretic of them all. The other resins are laxative to the bowels, promote the digestion of crudities, allay the violence of inveterate coughs, and, employed as a fumigation, disengage the

uterus of foreign bodies with which it is surcharged: they are particularly useful too as neutralizing the effects of mistletoe; and, mixed with bull suet and honey, they are curative of inflamed tumours and affections of a similar nature. The resin of the lentisk is very convenient as a bandoline for keeping stubborn eyelashes in their place: it is useful also in cases of fractures, suppurations of the ears, and prurigo of the generative organs. The resin of the pine is the best of them all for the cure of wounds in the head.

Detailed table of contents

CHAP. 23. (7.)

PITCH: TWENTY-THREE REMEDIES.

We have also stated on a previous occasion from what tree pitch is extracted, and the methods employed for that purpose. Of this also there are two kinds; thick pitch and liquid pitch. Of the several varieties of thick pitch the most useful for medicinal purposes is that of Bruttium; for being both extremely unctuous and very resinous, it reunites the properties both of resin and of pitch, that of a yellow reddish colour being the most highly esteemed. As to the statement made in addition to this, that the produce of the male tree is the best, I do not believe that any such distinction is at all possible.

Pitch is of a warming, cicatrizing tendency: mixed with polenta it is particularly useful as a neutralizer of the venom of the cerastes, and in combination with honey it is used for quinzy, catarrhs, and fits of sneezing caused by phlegm. With oil of roses it is used as an injection for the ears, and employed as a liniment with wax it heals lichens. It relaxes the bowels, also, and used as an electuary, or applied with honey to the tonsillary glands, it facilitates expectoration. Applied topically, it acts as a detergent upon ulcers, and makes new flesh. Mixed with raisins and axle-grease, it forms a detergent plaster for carbuncles and putrid ulcers, and, with pine-bark or sulphur, for serpiginous sores. Pitch has been administered too by some, in doses of one cyathus, for phthisis and inveterate coughs. It heals chaps of the Feet and rectum, inflamed tumours, and malformed nails; and used as a fumigation, it is curative of indurations and derangements of the uterus, and of lethargy. Boiled with barley-meal and the urine of a youth who has not arrived at puberty, it causes scrofulous sores to suppurate. Dry pitch is used also for the cure of alopecia. For affections of the mamillæ, Bruttian pitch is warmed in wine with fine spelt meal, and applied as hot as can be borne.

[Detailed table of contents](#)

CHAP. 24.

PISSELÆON AND PALIMPISSA: SIXTEEN REMEDIES.

We have already described the way in which liquid pitch and the oil known as pisselæon are made. Some persons boil the pitch over again, and give it the name of “palimpissa.” For quinzy and affections of the uvula, liquid pitch is employed internally. It is used also for the cure of ear-ache, for the improvement of the sight, and as a salve for the lips; and is employed for hysterical suffocations, inveterate coughs, profuse expectorations, spasms, nervousness, opisthotony, paralysis, and pains in the sinews. It is a very excellent remedy too for itch in dogs and beasts of burden.

[Detailed table of contents](#)

CHAP. 25.

PISSASPHALTOS: TWO REMEDIES.

There is pissasphaltos too, a natural production of the territory of the Apolloniates, and consisting of pitch mixed with bitumen. Some persons, however, make this mixture artificially, and employ it for the cure of itch in cattle, and of injuries done by the young sucklings to the mamillæ. The most esteemed portion of it is that which floats on the surface when boiled.

[Detailed table of contents](#)

CHAP. 26.

ZOPISSA: ONE REMEDY.

We have already stated that zopissa is the pitch, macerated with salt-water and wax, that has been scraped from off the bottoms of ships. The best kind is that taken from ships which have been to sea for the first time. It is used as an ingredient in plasters of an emollient nature, employed to disperse gatherings.

Detailed table of contents

CHAP. 27.

THE TORCH-TREE: ONE BEMEDY.

A decoction in vinegar of the wood of the torch-tree makes a most efficacious gargle for tooth-ache.

[Detailed table of contents](#)

CHAP. 28.

THE LENTISK: TWENTY-TWO REMEDIES.

The seed, bark, and tear-like juices of the lentisk are diuretics, and act astringently upon the bowels: a decoction of them, used as a fomentation, is curative of serpiginous sores, and is applied topically for humid ulcerations and erysipelas; it is employed also as a collutory for the gums. The teeth are rubbed with the leaves in cases of tooth-ache, and they are rinsed with a decoction of the leaves when loose: this decoction has the effect also of staining the hair. The gum of this tree is useful for diseases of the rectum, and all cases in which desiccatives and calorifics are needed; a decoction too of the gum is good for the stomach, acting as a carminative and diuretic; it is applied also to the head, in cases of headache, with polenta. The more tender of the leaves are used as an application for inflammations of the eyes.

The mastich produced by the lentisk is used as a bandoline for the hairs of the eye-lids, in compositions for giving a plumpness to the face, and in cosmetics for smoothing the skin. It is employed for spitting of blood and for inveterate coughs, as well as all those purposes for which gum acacia is in request. It is used also for the cure of excoriations; which are fomented either with the oil extracted from the seed, mixed with wax, or else with a decoction of the leaves in oil. Fomentations too are made of a decoction of it in water for diseases of the male organs. I know for a fact, that in the illness of Considia, the daughter of M. Servilius, a personage of consular rank, her malady, which had long resisted all the more severe methods of treatment, was at last successfully treated with the milk of goats that had been fed upon the leaves of the lentisk.

Detailed table of contents

CHAP. 29. (8.)

THE PLANE-TREE: TWENTY-FIVE REMEDIES.

The plane-tree neutralizes the bad effects of bites inflicted by the bat. The excrescences of this tree, taken in doses of four denarii, in wine, act as an antidote to the venom of serpents of all kinds and of scorpions, and are curative of burns. Pounded with strong vinegar, squill vinegar in particular, they arrest hæmorrhage of every kind; and with the addition of honey, they remove freckles, carcinomatous sores, and black spots of long standing on the skin.

The leaves again, and the bark of this tree, are used in the form of liniments for gatherings and suppurations, and a decoction of them is employed for a similar purpose. A decoction of the bark in vinegar is remedial for affections of the teeth, and the more tender of the leaves boiled in white wine are good for the eyes. The down which grows upon the leaves is injurious to both the ears and eyes. The ashes of the excrescences of this tree heal such parts of the body as have been burnt or frost-bitten. The bark, taken in wine, reduces the inflammation caused by the stings of scorpions.

[Detailed table of contents](#)

CHAP. 30.

THE ASH: FIVE REMEDIES.

We have already made some mention of the virtues possessed by the ash as an antidote to the venom of serpents. The seed of it is enclosed in follicules, which are good for diseases of the liver, and, in combination with wine, for pains in the sides: they are employed also for drawing off the water in dropsy. They have the property, too, of diminishing obesity, and of gradually reducing the body to a state of comparative emaciation, the follicules being pounded in wine and administered in proportion to the bodily strength; thus, for instance, to a child, five of them are given in three cyathi of wine, but for persons in more robust health, seven are prescribed, in five cyathi of wine.

We must not omit to state that the shavings and saw-dust of this wood are of a highly dangerous nature, according to some.

Detailed table of contents

CHAP. 31.

THE MAPLE: ONE REMEDY.

The root of the maple, beaten up in wine, is extremely efficacious as a topical application for pains in the liver.

[Detailed table of contents](#)

CHAP. 32.

THE POPLAR: EIGHT REMEDIES.

We have already mentioned, when speaking of the unguents, the use that is made of the berries of the white poplar. A potion prepared from the bark is good for sciatica and strangury, and the juice of the leaves is taken warm for ear-ache. So long as a person holds a sprig of poplar in his hand, there is no fear of chafing between the thighs.

The black poplar which grows in Crete is looked upon as the most efficacious of them all. The seed of it, taken in vinegar, is good for epilepsy. This tree produces a resin also to a small extent, which is made use of for emollient plasters. The leaves, boiled in vinegar, are applied topically for gout. A moisture that exudes from the clefts of the black poplar removes warts, and pimples caused by friction. Poplars produce also on the leaves a kind of sticky juice, from which bees prepare their propolis: indeed this juice, mixed with water, has the same virtues as propolis.

[Detailed table of contents](#)

CHAP. 33.

THE ELM: SIXTEEN REMEDIES.

The leaves, bark, and branches of the elm have the property of filling up wounds and knitting the flesh together: the inner membrane too, of the bark, and the leaves, steeped in vinegar, are applied topically for leprosy. The bark, in doses of one denarius, taken in one hemina of cold water, acts as a purgative upon the bowels, and is particularly useful for carrying off pituitous and aqueous humours. The gum also which this tree produces is applied topically to gatherings, wounds, and burns, which it would be as well to foment with the decoction also. The moisture which is secreted on the follicles of the tree gives a finer colour to the skin, and improves the looks. The foot-stalks of the leaves that first appear, boiled in wine, are curative of tumours, and bring them to a head: the same, too, is the effect produced by the inner bark.

Many persons are of opinion that the bark of this tree, chewed, is a very useful application for wounds, and that the leaves, bruised and moistened with water, are good for gout. The moisture too that exudes from the pith of the tree, as already stated, on an incision being made, applied to the head, causes the hair to grow and prevents it from falling off.

[Detailed table of contents](#)

CHAP. 34.

THE LINDEN-TREE: FIVE REMEDIES.

The linden-tree is useful, though in a less marked degree, for nearly all the same purposes as the wild olive. The leaves, however, are the only part that is made use of for ulcers upon infants; chewed, too, or employed in the form of a decoction, they are diuretic. Used as a liniment they arrest menstruation when in excess, and an infusion of them, taken in drink, carries off superfluous blood.

Detailed table of contents

CHAP. 35.

THE ELDER: FIFTEEN REMEDIES.

There are two kinds of elder, one of which grows wild and is much smaller than the other; by the Greeks it is known as the “chamæacte,” or “helion.” A decoction of the leaves, seed, or root of either kind, taken in doses of two cyathi, in old wine, though bad for the upper regions of the stomach, carries off all aqueous humours by stool. This decoction is very cooling too for inflammations, those attendant upon recent burns in particular. A poultice is made also of the more tender leaves, mixed with polenta, for bites inflicted by dogs. The juice of the elder, used as a fomentation, reduces abscesses of the brain, and more particularly of the membrane which envelopes that organ. The berries, which have not so powerful an action as the other parts of the tree, stain the hair. Taken in doses of one acetabulum, in drink, they are diuretic. The softer leaves are eaten with oil and salt, to carry off pituitous and bilious secretions.

The smaller kind is for all these purposes the more efficacious of the two. A decoction of the root in wine, taken in doses of two cyathi, brings away the water in dropsy, and acts emolliently upon the uterus: the same effects are produced also by a sitting-bath made of a decoction of the leaves. The tender shoots of the cultivated kind, boiled in a saucepan and eaten as food, have a purgative effect: the leaves taken in wine, neutralize the venom of serpents. An application of the young shoots, mixed with he-goat suet, is remarkably good for gout; and if they are macerated in water, the infusion will destroy fleas. If a decoction of the leaves is sprinkled about a place, it will exterminate flies. “Boa” is the name given to a malady which appears in the form of red pimples upon the body; for its cure the patient is scourged with a branch of elder. The inner bark, pounded and taken with white wine, relaxes the bowels.

Detailed table of contents

CHAP. 36.

THE JUNIPER: TWENTY-OXE REMEDIES.

The juniper is of a warming and resolvent nature beyond all other plants: in other respects, it resembles the cedar. There are two species of this tree, also, one of which is larger than the other: the odour of either, burnt, repels the approach of serpents. The seed is good for pains in the stomach, chest, and sides; it dispels flatulency and sudden chills, soothes cough, and brings indurations to a head. Applied topically, it checks the growth of tumours; and the berries, taken in red wine, act astringently upon the bowels: they are applied also to tumours of the abdomen. The seed is used as an ingredient in antidotes of an aperient nature, and is diuretic in its effects. It is used as a liniment for defluxions of the eyes, and is prescribed for convulsions, ruptures, griping pains in the bowels, affections of the uterus, and sciatica, either in a dose of four berries in white wine, or in the form of a decoction of twenty berries in wine.

There are persons who rub the body with juniper berries as a preventive of the attacks of serpents.

Detailed table of contents

CHAP. 37. (9.)

THE WILLOW: FOURTEEN REMEDIES. THE WILLOW OF AMLERIA: ONE REMEDY.

The fruit of the willow, before it arrives at maturity, is covered with a down like a spider's web: gathered before it is ripe, it arrests discharges of blood from the mouth. The bark of the upper branches, reduced to ashes and mixed with water, is curative of corns and callosities: it removes spots also upon the face, being still more efficacious for that purpose if mixed with the juices of the tree.

The juices produced by the willow form three different varieties; one of which exudes in the shape of a gum from the tree itself, and another distils from an incision some three fingers in width, made in the bark while the tree is in blossom. This last is very useful for dispersing humours which impede the sight, acting also as an inspissative when needed, promoting the discharge of the urine, and bringing abscesses of all kinds to a head. The third kind of juice exudes from the wounds, when the branches are lopt off with the bill. Either of these juices, warmed in a pomegranate rind, is used as an injection for diseases of the ears. The leaves, too, boiled and beaten up with wax, are employed as a liniment for similar purposes, and for gout. The bark and leaves, boiled in wine, form a decoction that is remarkably useful as a fomentation for affections of the sinews. The blossoms, bruised with the leaves, remove scaly eruptions of the face; and the leaves, bruised and taken in drink, check libidinous tendencies, and effectually put an end to them, if habitually employed.

The seed of the black willow of Ameria, mixed with litharge in equal proportions, and applied to the body just after the bath, acts as a depilatory.

[Detailed table of contents](#)

CHAP. 38.

THE VITEX: THIRTY-THREE REMEDIES.

Not much unlike the willow, for the use that is made of it in wicker-work, is the vitex, which also resembles it in the leaves and general appearance, though the smell of it is more agreeable. The Greeks call it “lygos,” or “agnos,” from the fact that the matrons of Athens, during the Thesmophoria, a period when the strictest chastity is observed, are in the habit of strewing their beds with the leaves of this tree.

There are two species of vitex: the larger one, like the willow, attains the full proportions of a tree; while the other, which is smaller, is branchy, with a paler, downy leaf. The first kind, generally known as the “white” vitex, bears a white blossom mixed with purple, whereas the black one has a flower that is entirely purple. Both of these trees grow on level spots of a marshy nature.

The seed of these trees, taken in drink, has a sort of vinous flavour, and has the reputation of being a febrifuge. It is said also to act as a sudorific, if the body is rubbed with it mixed with oil, and to have the effect of dispelling extreme lassitude: it acts too as a diuretic and emmenagogue. The produce of both trees is trying to the head, like wine, and indeed the odour of them is very similar. They have the effect also of removing flatulence in the lower regions of the body, act astringently upon the bowels, and are remarkably useful for dropsy and affections of the spleen. They promote the secretion of the milk, and neutralize the venom of serpents, when of a cold nature more particularly. The smaller kind, however, is the more efficacious of the two for injuries inflicted by serpents, the seed being taken in doses of one drachma, in wine or oxycrate, or else the more tender leaves in doses of two drachmæ.

From both trees also a liniment is prepared for the bites of spiders, but it is quite sufficient to rub the wounds with the leaves; and if a fumigation is made from them, or if they are spread beneath the bed, they will repel the attacks of all venomous creatures. They act also as an antaphrodisiac, and it is by this tendency in particular that they neutralize the venom of the phalangium, the bite of which has an exciting effect upon the generative organs. The blossoms and young shoots, mixed with oil of roses, allay head-aches arising from inebriation. A decoction of the seed used as a fomentation cures head-ache, however intense it may be; and employed as a fumigation or as a pessary, the seeds acts as a detergent upon the uterus. Taken in drink with honey and penny-royal, it has a laxative effect; pounded and used with barley-meal, it quickly brings abscesses and hard tumours to a head, and has an emollient effect.

The seed, in combination with saltpetre and vinegar, removes lichens and freckles; mixed with honey, it heals ulcers and eruptions of the mouth; applied with butter and vine-leaves, it reduces swellings of the testes; used with water,

as a lini- ment, it cures chaps of the rectum; and employed with salt, nitre, and wax, it is good for sprains. The seed and leaves are used as ingredients also in emollient plasters for diseases of the sinews, and for gout; and a decoction of the seed in oil is employed as a fomentation for the head in cases of phrenitis and lethargy. Persons who carry a sprig of this plant in the hand, or stuck in the girdle, will be proof, it is said, against chafing between the thighs.

Detailed table of contents

CHAP. 39.

THE ERICA; ONE REMEDY.

The Greeks give the name of “erice,” to a shrub that is but little different from the myrice. It has the colour, and very nearly the leaf, of rosemary. It neutralizes the venom of serpents, it is said.

Detailed table of contents

CHAP. 40.

THE BROOM; FIVE REMEDIES.

The broom is used for making withes; the flowers of it are greatly sought by bees. I have my doubts whether this is not the same plant that the Greek writers have called “sparton,” and of which, in those parts of the world, as I have already stated, they are in the habit of making fishing-nets. I doubt also whether Homer has alluded to this plant, when he speaks of the seams of the ships,— “the sparta” coming asunder; for it is certain that in those times the spartum of Spain or Africa was not as yet in use, and that vessels made of materials sown together, were united by the agency, not of spartum, but of flax.

The seed of the plant to which the Greeks now give the name of “sparton,” grows in pods like those of the kidneybean. It is as strongly drastic as hellebore, and is usually taken fasting, in doses of one drachma and a half, in four cyathi of hydromel. The branches also, with the foliage, are macerated for several days in vinegar, and are then beaten up, the infusion being recommended for sciatica, in doses of one cyathus. Some persons think it a better plan, however, to make an infusion of them in sea-water, and to inject it as a clyster. The juice of them is used also as a friction for sciatica, with the addition of oil. Some medical men, too, make use of the seed for strangury. Broom, bruised with axle-grease, is a cure for diseases of the knees.

Detailed table of contents

CHAP. 41.

THE MYRICA, OTHERWISE CALLED TAMARICA, OR TAMARIX: THREE REMEDIES.

Lenæus says, that the myrice, otherwise known as the “crica,” is a similar plant to that of which brooms are made at Aneria. He states also that, boiled in wine and then beaten up and applied with honey, it heals carcinomatous sores. I would here remark, parenthetically, that some persons identify it with the tamarice. Be this as it may, it is particularly useful for affections of the spleen, the juice of it being extracted for the purpose, and taken in wine; indeed so marvellous, they say, is its antipathy to this part of the viscera, and this only, that if swine drink from troughs made of this wood, they will be found to lose the spleen. Hence it is that in maladies of the spleen victuals and drink are given to the patient in vessels made of this wood.

A medical author too, of high reputation, has asserted that a sprig broken from off this tree, without being allowed to touch the earth or iron, will allay pains in the bowels, if applied to the body, and kept close to it by the clothes and girdle. The common people, as already stated, look upon this tree as illomened, because it bears no fruit, and is never propagated from seed.

Detailed table of contents

CHAP. 42.

THE BBYA: TWENTY-NINE REMEDIES.

At Corinth, and in the vicinity of that city, the Greeks give the name of “brya” to a plant of which there are two varieties; the wild brya, which is altogether barren, and the cultivated one. This last, when found in Syria and Egypt, produces a ligneous fruit, somewhat larger than a gall-nut, in great abundance, and of an acrid flavour; medical men employ it as a substitute for galls in the compositions known as “antheræ.” The wood also, with the blossoms, leaves, and bark of the tree, is used for similar purposes, but their properties are not so strongly developed. The bark is pounded also, and given for discharges of blood from the mouth, irregularities of the catamenia, and cœliac affections: beaten up and applied to the part affected, it checks the increase of all kinds of abscesses.

The juice too is extracted from the leaves for similar purposes, and a decoction is made of them in wine; they are applied also to gangrenes, in combination with honey. A decoction of them taken in wine, or the leaves themselves applied with oil of roses and wax, has a sedative effect: it is in this form that they are used for the cure of epinyctis. This decoction is useful also for tooth-ache or ear-ache, and the root is employed for similar purposes. The leaves too have this additional use — they are applied with polenta to serpiginous sores. The seed, in doses of one drachma, is administered in drink for injuries inflicted by spiders or the phalangium; and mixed with the grease of poultry, it is applied to boils. It is very efficacious also for stings inflicted by all kinds of serpents, the asp excepted. The decoction, used as a fomentation, is curative of jaundice, phthiriasis, and lice; it also arrests the catamenia when in excess. The ashes of the tree are employed for all these purposes; there is a story told, too, that, mixed with the urine of an ox, and taken in the food or drink, they will act most effectually as an antaphrodisiac. The charcoal too of this wood is quenched in urine of a similar nature, and kept in a shady spot. When it is the intention of the party to rekindle the flames of desire, it is set on fire again. The magicians say, that the urine of an eunuch will have a similar effect.

Detailed table of contents

CHAP. 43.

THE BLOOD-RED SHRUB: ONE REMEDY.

Nor is the blood-red shrub looked upon as a less ill-omened plant than the last. The inner bark of it is used to re-open ulcers which have healed too rapidly.

[Detailed table of contents](#)

CHAP. 44.

THE SILER: THREE REMEDIES.

The leaves of the siler, applied to the forehead, allay head-ache; and the seed of it, beaten up with oil, is curative of phthiriasis. Serpents also are greatly in dread of this tree, and it is for this reason that the country-people are in the habit of carrying a walking-stick made of it.

Detailed table of contents

CHAP. 45.

THE PRIVATE: EIGHT REMEDIES.

The ligustrum, or privet, if it is the same tree as the cyprus of the East, has also its own medicinal uses in Europe. The juice of it is used for affections of the sinews and joints, and for sudden chills; and the leaves are universally employed, with a sprinkling of salt, for the cure of inveterate sores and of ulcerations of the mouth. The berries are curative of phthiriasis and chatings between the thighs, for which last purpose the leaves also are employed. The berries are made use of for the cure of pip in poultry.

[Detailed table of contents](#)

CHAP. 46.

THE ALDER: ONE KEMEDY.

The leaves of the alder, steeped in boiling water, are an undoubted remedy for tumours.

Detailed table of contents

CHAP. 47.

THE SEVERAL VARIETIES OF THE IVY: THIRTY-NINE REMEDIES

We have already enumerated some twenty varieties of the ivy. The medicinal properties of them all are of a doubtful nature; taken in considerable quantities they disturb the mental faculties and purge the brain. Taken internally they are injurious to the sinews, but applied topically they are beneficial to those parts of the body. Ivy possesses properties similar to those of vinegar. All the varieties of the ivy are of a refrigerative nature, and taken in drink they are diuretic. The softer leaves, applied to the head, allay head-ache, acting more particularly upon the brain and the membrane which envelopes that organ. For this purpose the leaves are bruised with vinegar and oil of roses and then boiled, after which some more rose-oil is added. The leaves too are applied to the fore-head, and the mouth is fomented with a decoction of them, with which the head is rubbed as well. They are useful also for the spleen, the leaves being applied topically, or an infusion of them taken in drink. A decoction of them is used for cold shiverings in fevers, and for pituitous eruptions; or else they are beaten up in wine for the purpose. The umbels too, taken in drink or applied externally, are good for affections of the spleen, and an application of them is useful for the liver; employed as a pessary, they act as an emmenagogue. The juice of the ivy, the white cultivated kind more particularly, cures diseases of the nostrils and removes habitually offensive smells. Injected into the nostrils it purges the head, and with the addition of nitre it is still more efficacious for that purpose. In combination with oil, the juice is injected for suppurations or pains in the ears. It is a corrective also of the deformities of scars. The juice of white ivy, heated with the aid of iron, is still more efficacious for affections of the spleen; it will be found sufficient, however, to take six of the berries in two cyathi of wine. Three berries of the white ivy, taken in oxymel, expel tape-worm, and in the treatment of such cases it is a good plan to apply them to the abdomen as well. Erasistratus prescribes twenty of the golden-coloured berries of the ivy which we have-mentioned as the "chrysocarpos," to be beaten up in one sextarius of wine, and he says that if three cyathi of this preparation are taken for dropsy, it will carry off by urine the water that has been secreted beneath the skin. For cases of tooth-ache he recommends five berries of the chrysocarpos to be beaten up in oil of roses, and warmed in a pomegranate-rind, and then injected into the ear opposite the side affected. The berries which yield a juice of a saffron colour, taken beforehand in drink, are a preservative against crapulence; they are curative also of spitting of blood and of griping pains in the bowels. The whiter umbels of the black ivy, taken in drink, are productive of sterility, in males even. A decoction in wine of any kind of ivy is useful as a liniment for all sorts of ulcers, those even of the malignant kind known as "cacoethes."

The tears which distil from the ivy are used as a depilatory, and for the cure of phthiriasis. The blossoms too, of all the varieties, taken twice a day in astringent wine, a pinch in three fingers at a time, are curative of dysentery and looseness of the bowels: they are very useful also, applied to burns with wax. The umbels stain the hair black. The juice extracted from the root is taken in vinegar for the cure of wounds inflicted by the phalangium. I find it stated too, that patients suffering from affections of the spleen are cured by drinking from vessels made of the wood of the ivy. The berries are bruised also, and then burnt, and a liniment is prepared from them for burns, the parts being fomented with warm water first.

Incisions are sometimes made in the ivy to obtain the juice, which is used for carious teeth, it having the effect of breaking them, it is said; the adjoining teeth being fortified with wax against the powerful action of the juice. A kind of gum even is said to be found in the ivy, which, it is asserted, is extremely useful, mixed with vinegar, for the teeth.

[Detailed table of contents](#)

CHAP. 48.

THE CISTHOS: FIVE REMEDIES.

The Greeks give the name of “cisthos” — a word very similar to “cissos,” the Greek name of the ivy — to a plant which is somewhat larger than thyme, and has a leaf like that of ocimum. There are two varieties of this plant; the male, which has a rose-coloured blossom, and the female, with a white one. The blossom of either kind, taken in astringent wine, a pinch in three fingers at a time, is good for dysentery and looseness of the bowels. Taken in a similar manner twice a day, it is curative of inveterate ulcers: used with wax, it heals burns, and employed by itself it cures ulcerations of the mouth. It is beneath these plants more particularly that the hypocisthis grows, of which we shall have occasion to speak when treating of the herbs.

Detailed table of contents

CHAP. 49.

THE CISSOS ERYTIRANOS: TWO REMEDIES. THE CHAMÆCISSOS: TWO REMEDIES. THE SMILAX: THREE REMEDIES. THE CLEMATIS: EIGHTEEN REMEDIES.

The plant called “cissos erythranos” by the Greeks, is similar to the ivy: taken in wine, it is good for sciatica and lumbago. The berries, it is said, are of so powerful a nature as to produce bloody urine. “Chamæcissos” also is a name given by them to a creeping ivy which never rises from the surface of the ground: bruised in wine, in doses of one acetabulum, it is curative of affections of the spleen, the leaves of it being applied topically with axle-grease to burns.

The smilax also, otherwise known as the “anthophoros,” has a strong resemblance to ivy, but the leaves of it are smaller. A chaplet, they say, made of an uneven number of the leaves, is an effectual cure for head-ache. Some writers mention two kinds of smilax, one of which is all but perennial, and is found climbing the trees in umbrageous valleys, the berries hanging in clusters. These berries, they say, are remarkably efficacious for all kinds of poisons; so much so indeed, that infants to whom the juice of them has been habitually administered, are rendered proof against all poisons for the rest of their life. The other kind, it is said, manifests a predilection for cultivated localities, and is often found growing there; but as for medicinal properties, it has none. The former kind, they say, is the smilax, the wood of which we have mentioned as emitting a sound, if held close to the ear.

Another plant, similar to this, they call by the name of “clematis:” it is found adhering to trees, and has a jointed stem. The leaves of it cleanse leprous sores, and the seed acts as an aperient, taken in doses of one acetabulum, in one hemina of water, or in hydromel. A decoction of it is prescribed also for a similar purpose.

Detailed table of contents

CHAP. 50. (11.)

THE REED: NINETEEN REMEDIES.

We have already treated of twenty-nine varieties of the reed, and there is none of her productions in which that mighty power of Nature, which in our successive Books we have described, is more fully displayed than in this. The root of the reed, pounded and applied to the part affected, extracts the prickles of fern from the body, the root of the fern having a similar effect upon splinters of the reed. Among the numerous varieties which we have described, the scented reed which is grown in Judæa and Syria as an ingredient in our unguents, boiled with hay-grass or parsley-seed, has a diuretic effect: employed as a pessary, it acts as an emmenagogue. Taken in drink, in doses of two oboli, it is curative of convulsions, diseases of the liver and kidneys, and dropsy. Used as a fumigation, and with resin more particularly, it is good for coughs, and a decoction of it with myrrh is useful for scaly eruptions and running ulcers. A juice, too, is collected from it which has similar properties to those of elaterium.

In every kind of reed the part that is the most efficacious is that which lies nearest the root; the joints also are efficacious in a high degree. The ashes of the Cyprian reed known as the “donax,” are curative of alopecia and putrid ulcers. The leaves of it are also used for the extraction of pointed bodies from the flesh, and for erysipelas and all kinds of gatherings. The common reed, beaten up quite fresh, has also considerable extractive powers, and not in the root only, for the stem, it is said, has a similar property. The root is used also in vinegar as a topical application for sprains and for pains in the spine; and beaten up fresh and taken in wine it acts as an aphrodisiac. The down that grows on reeds, put into the ears, deadens the hearing.

[Detailed table of contents](#)

CHAP. 51.

THE PAPYRUS AND THE PAPER MADE FROM IT: THREE REMEDIES.

Of a kindred nature with the reed is the papyrus of Egypt; a plant that is remarkably useful, in a dried state, for dilating and drying up fistulas, and, by its expansive powers, opening an entrance for the necessary medicaments. The ashes of paper prepared from the papyrus are reckoned among the caustics: those of the plant, taken in wine, have a narcotic effect. The plant, applied topically in water, removes callosities of the skin.

Detailed table of contents

CHAP. 52.

THE EBONY: FIVE REMEDIES.

The ebony-tree does not grow in Egypt even, as we have already stated, and it is not our intention to speak here of the medicinal properties of the vegetable productions of foreign climates. Still, however, the ebony must not be omitted, on account of the marvels related of it. The saw-dust of this wood, it is said, is a sovereign remedy for diseases of the eyes, and the pulp of the wood, rubbed upon a whetstone moistened with raisin wine, dispels all films which impede the sight. The root too, they say, applied with water, is curative of white specks in the eyes, and, with the addition of root of dracunculus, in equal proportions, and of honey, of cough. Medical men reckon ebony also in the number of the caustics.

Detailed table of contents

CHAP. 53

THE RHODODENDRON: ONE REMEDY.

The rhododendron has not so much as found a Latin name among us, its other names being “rhododaphne” and “nerium.” It is a marvellous fact, but the leaves of this plant are poisonous to quadrupeds; while for man, if taken in wine with rue, they are an effectual preservative against the venom of serpents. Sheep too, and goats, it is said, if they drink water in which the leaves have been steeped, will die immediately.

[Detailed table of contents](#)

CHAP. 54.

THE RHUS OR SUMACH-TREE; TWO VARIETIES OF IT: EIGHT REMEDIES.
STOMATICE.

Nor vet has the tree called “rhus” any Latin name, although it is employed in numerous ways. Under this name are comprehended a wild plant, with leaves like those of myrtle, and a short stem, which is good as an expellent of tapeworm; and the shrub which is known as the “currier’s plant,” of a reddish colour, a cubit in height, and about the thickness of one’s finger, the leaves of which are dried and used, like pomegranate rind, for curing leather.

Medical men also employ the leaves of these plants for the treatment of contusions, and for the cure of cœliac affections, and of ulcers of the rectum and phagedænic sores; for all which purposes they are pounded with honey and applied with vinegar. A decoction of them is injected for suppurations of the ears. With the branches, boiled, a stomatice is also made, which is used for the same purposes as that prepared from mulberries; it is more efficacious, however, mixed with alum. This preparation is applied also to reduce the swelling in dropsy.

Detailed table of contents

CHAP. 55.

RHUS ERYTHROS: NINE REMEDIES.

Rhus erythros is the name given to the seed of this shrub. It possesses properties of an astringent and cooling nature, and is used as a seasoning for provisions, in place of salt. It has a laxative effect, and, used in conjunction with silphium, it gives a finer flavour to meat of all kinds. Mixed with honey, it is curative of running ulcers, pimples on the tongue, contusions, bruises, and excoriations. It causes ulcers of the head to cicatrize with the greatest rapidity; and taken with the food, it arrests excessive menstruation.

[Detailed table of contents](#)

CHAP. 56.

THE ERYTHIRODANXU: ELEVEN REMEDIES.

The erythrodanus, by some called “ereuthodanus,” and in Latin, “rubia,” is quite a different plant. It is used for dyeing wool, and skins for leather are prepared with it. Used medicinally, it is a diuretic, and, employed with hydronel, it is turative of jaundice. Employed topically with vinegar, it leals lichens; and a potion is prepared from it for sciatica and paralysis, the patient while using it taking a bath daily. The root of it and the seed are effectual as an emmenagogue the act astringently upon the bowels, and disperse gatherings. The branches, together with the leaves, are applied to wounds inflicted by serpents; the leaves too have the property of staining the hair. I find it stated by some writers that this shrub is curative of jaundice, even if worn as an amulet only, and looked at every now and then.

Detailed table of contents

CHAP. 57.

THE ALYSSON: TWO REMEDIES.

The plant known as the “Alyson” differs only from the preceding one in the leaves and branches, which are more diminutive. It receives its name from the fact, that, taken in vinetar and worn as an amulet, it prevents persons bitten by dogs from becoming rabid. It is a marvellous fact too, that is added to the effect that the person bitten has only to look at thi shrub, and the flow of corrupt matter from the wound will b staunchd immediately.

Detailed table of contents

CHAP. 58.

THE RADICULT OR STRUTHION; THIRTEEN REMEDIES. THE APOCYNUMI: TWO OBSERVATIONS UPON IT.

The adicula, which we have already mentioned as being called “struthion” by the Greeks, is used by dyers for preparing Wool. A decoction of it, taken internally, is curative of jaunoe and diseases of the chest. It is diuretic also, and laxative and acts as a detergent upon the uterus, for which reasons medical men have given it the name of the “golden beverage.” Taken with honey, it is a sovereign remedy for cough; and it is used for hardness of breathing, in doses of a spoonful. Applied with polenta and vinegar to the pats affected, it removes leprous sores. Used with panax and not of the caper-plant, it breaks and expels calculi, and a decoction of it in wine with barley-meal disperses inflamed tumours. It is used as an ingredient in emollient plasters and eye-sakes for the sight, and is found to be one of the most useful stenutories known; it is good too for the liver and the spleen. Taken in hydromel, in doses of one denarius, it effects the cure of asthma, as also of pleurisy and all pains in the sides.

The apocynum is a shrub with leaves like those of ivy, hit softer, and not so long in the stalk, and the seed of it is pointed and downy, with a division running down it, and a very powerful smell. Given in their food with water, the eed is poisonous to dogs and all other quadrupeds.

Detailed table of contents

CHAP. 59.

ROSEMARY: EIGHTEEN REMEDIES.

There are two kinds of rosemary; one of which is baren, and the other has a stem with a resinous seed, known as “cachrys.” The leaves have the odour of frankincense. The root, applied fresh, effects the cure of wounds, proapsus of the rectum, condylomata, and piles. The juice of the plant, as well as of the root, is curative of jaundice, and such diseases as require detergents; it is useful also for the sight. The seed is given in drink for inveterate diseases of the chest, and, with wine and pepper, for affections of the uterus; it acts also as an emmenagogue, and is used with meal of dandelion as a liniment for gout. It acts also as a detergent upon freckles, and is used as an application in diseases which require calorifics or sudorifics, and for convulsions. The plant itself, or else the root, taken in wine, increases the milk, and the leaves and stem of the plant are applied with vinegar to scrofulous sores; used with honey, they are very useful for cough.

[Detailed table of contents](#)

CHAP. 60.

THE SEED CALLED CACHRYS.

As already stated, there are several kinds of cachrys; but that which is produced by rosemary above-mentioned, when rubbed, is found to be of a resinous nature. It neutralizes poisons and the venom of animals, that of serpents excepted. It acts also as a sudorific, dispels griping pains in the bowels, and increases the milk in nursing women.

[Detailed table of contents](#)

CHAP. 61.

THE HERB SAVIN: SEVEN REMEDIES.

Of the herb savin, known as “brathy” by the Greeks, there are two varieties, one of them with a leaf like that of the tamarix, the other with that of the cypress; for which reason some persons have called this last the Cretan cypress. It is used by many for fumigations, as a substitute for frankincense; employed in medicine, it is said to have the same effect as cinnamon, if taken in doses twice as large. It reduces gatherings, disperses corrosive sores, acts as a detergent upon ulcers, and, used as a pessary and as a fumigation, brings away the dead fœtus. It is employed as a topical application for erysipelas and carbuncles, and, taken with honey in wine, is curative of jaundice.

The smoke of this plant, they say, cures the pip in all kinds of poultry.

Detailed table of contents

CHAP. 62.

SELAGO: TWO REMEDIES.

Similar to savin is the herb known as “selago.” Care is taken to gather it without the use of iron, the right hand being passed for the purpose through the left sleeve of the tunic, as though the gatherer were in the act of committing a theft. The clothing too must be white, the Feet bare and washed clean, and a sacrifice of bread and wine must be made before gathering it: it is carried also in a new napkin. The Druids of Gaul have pretended that this plant should be carried about the person as a preservative against accidents of all kinds, and that the smoke of it is extremely good for all maladies of the eyes.

Detailed table of contents

CHAP. 63.

SAMOLUS: TWO REMEDIES.

The Druids, also, have given the name of “samolus” to a certain plant which grows in humid localities. This too, they say, must be gathered fasting with the left hand, as a preservative against the maladies to which swine and cattle are subject. The person, too, who gathers it must be careful not to look behind him, nor must it be laid anywhere but in the troughs from which the cattle drink.

[Detailed table of contents](#)

CHAP. 64.

GUM: ELEVEN REMEDIES.

We have already spoken of the different kinds of gum; the better sort of each kind will be found the most effective. Gum is bad for the teeth; it tends to make the blood coagulate, and is consequently good for discharges of blood from the mouth. It is useful for burns, but is bad for diseases of the trachea. It exercises a diuretic effect, and tends to neutralize all acridities, being astringent in other respects. The gum of the bitter-almond tree, which has the most astringent properties of them all, is calorific also in its effects. Still, however, the gum of the plum, cherry, and vine is greatly preferred: all which kinds, applied topically, are productive of astringent and desiccative effects, and, used with vinegar, heal lichens upon infants. Taken in must, in doses of four oboli, they are good for inveterate coughs.

It is generally thought that gum, taken in raisin wine, improves the complexion, sharpens the appetite, and is good for calculi in the bladder. It is particularly useful too for wounds and affections of the eyes.

Detailed table of contents

CHAP. 65. (12.)

THE EGYPTIAN OR ARABIAN THORN: FOUR REMEDIES.

When speaking of the perfumes, we have descanted upon the merits of the Egyptian or Arabian thorn. This, too, is of an astringent nature, and acts as a desiccative upon fluxes of all kinds, discharges of blood from the mouth, and excessive menstruation; for all which purposes the root is still more efficacious.

Detailed table of contents

CHAP. 66.

THE WHITE THORN: TWO REMEDIES. THE ACANTHION; ONE REMEDY.

The seed of the white thorn is useful as a remedy for the stings of scorpions, and a chaplet made of it, is good for headache. Similar to this plant is that known to the Greeks as the “acanthion;” though it is much smaller in the leaf, which is pointed at the extremity, and covered with a down like a cobweb in appearance. This downy substance is gathered in the East, and certain textures are made of it similar to those of silk. An infusion of the leaves or root of this plant is taken for the cure of opisthotony.

[Detailed table of contents](#)

CHAP. 67.

GUM ACACIA: EIGHTEEN REMEDIES.

Gum acacia is produced also from the white and black thorns of Egypt, and from a green thorn as well; the produce, however, of the former trees is by far the best. There is also a similar gum found in Galatia, but of very inferior quality, the produce of a more thorny tree than those last mentioned. The seed of all these trees resembles the lentil in appearance, only that it is smaller, as well as the pod which contains it: it is gathered in autumn, before which period it would be too powerful in its effects. The juice is left to thicken in the pods, which are steeped in rain-water for the purpose, and then pounded in a mortar; after which, the juice is extracted by means of presses. It is then dried in the mortars in the sun, and when dry is divided into tablets. A similar juice is extracted from the leaves, but it is by no means so useful as the other. The seed is used also, as a substitute for nut-galls in curing leather.

The juice extracted from the leaves, as also the extremely black juice of the Galatian acacia, is held in no esteem. The same too with that of a deep red colour. The gum which is of a purple, or of an ashy, grey colour, and which dissolves with the greatest rapidity, possesses the most astringent and cooling qualities of them all, and is more particularly useful as an ingredient in compositions for the eyes. When required for these purposes, the tablets are steeped in water by some, while some again scorch them, and others reduce them to ashes. They are useful for dyeing the hair, and for the cure of erysipelas, serpiginous sores, ulcerations of the humid parts of the body, gatherings, contusions of the joints, chilblains, and hangnails. They are good also for cases of excessive menstruation, procidence of the uterus and rectum, affections of the eyes, and ulcerations of the generative organs and mouth.

[Detailed table of contents](#)

CHAP. 68. (13.)

ASPALATHOS: ONE REMEDY.

The common thorn too, with which the fulling coppers are filled, is employed for the same purposes as the radícula. In the provinces of Spain it is commonly employed as an ingredient in perfumes and unguents, under the name of “aspalathos.” There is no doubt, however, that there is also a wild thorn of the same name in the East, as already mentioned, of a white colour, and the size of an ordinary tree.

Detailed table of contents

CHAP. 69.

THE ERYSISCEPTRUM, ADIPSATHEON, OR DIAXYLON: EIGHT REMEDIES.

There is also found in the islands of Nisyros and of Rhodes, a shrub of smaller size, but full as thorny, known by some as the erysisceptrum, by others as the adipsatheon, and by the Syrians as the diaxylon. The best kind is that which is the least ferulaceous in the stem, and which is of a red colour, or inclining to purple, when the bark is removed. It is found growing in many places, but is not everywhere odoriferous. We have already stated how remarkably sweet the odour of it is, when the rainbow has been extended over it.

This plant cures fetid ulcers of the mouth, polypus of the nose, ulcerations or carbuncles of the generative organs, and chaps; taken in drink it acts as a carminative, and is curative of strangury. The bark is good for patients troubled with discharges of blood, and a decoction of it acts astringently on the bowels. It is generally thought that the wild plant is productive of the same effects.

Detailed table of contents

CHAP. 70.

THE THORN CALLED APPENDIX: TWO REMEDIES. THE PYRACANTHA: ONE
REMEDY.

There is a thorn also known as the appendix; that name being given to the red berries which hang from its branches. These berries eaten by themselves, raw, or else dried and boiled in wine, arrest looseness of the bowels and dispel griping pains in the stomach. The berries of the pyracantha are taken in drink for wounds inflicted by serpents.

Detailed table of contents

CHAP. 71.

THE PALIURUS: TEN REMEDIES.

The paliurus, too, is a kind of thorn. The seed of it, known by the people of Africa as “zura,” is extremely efficacious for the sting of the scorpion, as also for urinary calculi and cough. The leaves are of an astringent nature, and the root disperses inflamed tumours, gatherings, and abscesses; taken in drink it is diuretic in its effects. A decoction of it in wine arrests diarrhea, and neutralizes the venom of serpents: the root more particularly is administered in wine.

Detailed table of contents

CHAP. 72.

THE AGRIFOLIA. THE AQUIFOLIA: ONE REMEDY. THE YEW: ONE PROPERTY
BELONGING TO IT.

The agrifolia, pounded, with the addition of salt, is good for diseases of the joints, and the berries are used in cases of excessive menstruation, cœliac affections, dysentery, and cholera; taken in wine, they act astringently upon the bowels. A decoction of the root, applied externally, extracts foreign bodies from the flesh, and is remarkably useful for sprains and tumours.

The tree called “aquifolia,” planted in a town or country- house, is a preservative against sorceries and spells. The blossom of it, according to Pythagoras, congeals water, and a staff made of the wood, if, when thrown at any animal, from want of strength in the party throwing it, it falls short of the mark, will roll back again towards the thrower, of its own accord — so remarkable are the properties of this tree. The smoke of the yew kills rats and mice.

Detailed table of contents

CHAP. 73.

THE BRAMBLE: FIFTY-ONE REMEDIES.

Nor yet has Nature destined the bramble to be only an annoyance to mankind, for she has bestowed upon it mulberries of its own, or, in other words, a nutritive aliment even for mankind. These berries are of a desiccative, astringent, nature, and are extremely useful for maladies of the gums, tonsillary glands, and generative organs. They neutralize also the venom of those most deadly of serpents, the hæmorrhoids and the prester; and the flowers or fruit will heal wounds inflicted by scorpions, without any danger of abscesses forming. The shoots of the bramble have a diuretic effect: and the more tender ones are pounded, and the juice extracted and then dried in the sun till it has attained the consistency of honey, being considered a most excellent remedy, taken in drink or applied externally, for maladies of the mouth and eyes, discharges of blood from the mouth, quinzy, affections of the uterus, diseases of the rectum, and celiac affections. The leaves, chewed, are good for diseases of the mouth, and a topical application is made of them for running ulcers and other maladies of the head. In the cardiac disease they are similarly applied to the left breast by themselves. They are applied topically also for pains in the stomach and for procidence of the eyes. The juice of them is used as an injection for the ears, and, in combination with cerate of roses, it heals condylomata.

A decoction of the young shoots in wine is an instantaneous remedy for diseases of the uvula; and eaten by themselves like cymæ, or boiled in astringent wine, they strengthen loose teeth. They arrest fluxes of the bowels also, and discharges of blood, and are very useful for dysentery. Dried in the shade and then burnt, the ashes of them are curative of procidence of the uvula. The leaves too, dried and pounded, are very useful, it is said, for ulcers upon beasts of burden. The berries produced by this plant would seem to furnish a stomatice superior even to that prepared from the cultivated mulberry. Under this form, or else only with hypocisthis and honey, the berries are administered for cholera, the cardiac disease, and wounds inflicted by spiders.

Among the medicaments known as “styptics,” there is none that is more efficacious than a decoction of the root of the bramble in wine, boiled down to one third. Ulcerations of the mouth and rectum are bathed with it, and fomentations of it are used for a similar purpose; indeed, it is so remarkably powerful in its effects, that the very sponges which are used become as hard as a stone.

CHAP. 74.

HE CYNOSBATOS: THREE REMEDIES.

There is another kind of bramble also, which bears a rose. It produces a round excrescence, similar to a chesnut in appearance, which is remarkably valuable as a remedy for calculus. This is quite a different production from the “cynorrhoda,” which we shall have occasion to speak of in the succeeding Book.

(14.) The cynosbatos is by some called “cynapanxis,” and by others “neurospastos;” the leaf resembles the human footstep in shape. It bears also a black grape, in the berries of which there is a nerve, to which it is indebted for its name of “neurospastos.” It is quite a different plant from the capparis or caper, to which medical men have also given the name of “cynosbatos.” The clusters of it, pickled in vinegar, are eaten as a remedy for diseases of the spleen, and flatulency: and the string found in the berries, chewed with Chian mastich, cleanses the mouth.

The rose of the bramble, mixed with axle-grease, is curative of alopecia: and the bramble-berries themselves, combined with oil of omphacium, stain the hair. The blossom of the bramble is gathered at harvest, and the white blossom, taken in wine, is an excellent remedy for pleurisy and cœliac affections. The root, boiled down to one third, arrests looseness of the bowels and hemorrhage, and a decoction of it, used as a gargle, is good for the teeth: the juice too is employed as a fomentation for ulcers of the rectum and generative organs. The ashes of the root are curative of relaxations of the uvula.

Detailed table of contents

CHAP. 75.

THE IDÆAN BRAMBLE.

The Idæan bramble is so called from the fact that it is the only plant of the kind found growing upon Mount Ida. It is of a more delicate nature than the others, and smaller; the canes too are thinner, and not so prickly: it mostly grows beneath the shade of trees. The blossom of it, mixed with honey, is applied topically for defluxions of the eyes, and is administered in water for erysipelas and affections of the stomach. In other respects, it has properties similar to those of the plants already mentioned.

[Detailed table of contents](#)

CHAP. 76.

THE RHAMNOS; TWO VARIETIES OF IT: FIVE REMEDIES.

Among the several kinds of bramble is reckoned the plant called “rhamnos” by the Greeks. One variety of it is whiter than the other, and has a more shrublike appearance, throwing out branches armed with straight thorns, and not hooked, like those of the other kinds; the leaves too are larger. The other kind, which is found growing wild, is of a more swarthy hue, in some measure inclining to red; it bears too a sort of pod. With the root of it boiled in water a medicament is made, known as “lycium:” the seed of it is useful for bringing away the after-birth. The white kind, however, is of a more astringent and cooling nature, and better adapted for the treatment of gatherings and wounds. The leaves of both kinds, either raw or boiled, are employed topically with oil.

Detailed table of contents

CHAP. 77.

LYCIUM: EIGHTEEN REMEDIES.

The best lycium, they say, is that prepared from the thorn of that name, known also as the “Chironian pyxacanthus,” and mentioned by us when speaking of the trees of India, the lycium of those regions being generally looked upon as by far the best. The branches and roots, which are intensely bitter, are first pounded and then boiled for three days in a copper vessel, after which the woody parts are removed, and the decoction is boiled again, till it has attained the consistency of honey. It is adulterated with various bitter extracts, as also with amurca of olive oil and ox-gall. The froth or flower of this decoction is used as an ingredient in compositions for the eyes: and the other part of it is employed as a cosmetic for the face, and for the cure of itch-scabs, corroding sores in the corners of the eyes, inveterate fluxes, and suppurations of the ears. It is useful too for diseases of the tonsillary glands and gums, for coughs, and for discharges of blood from the mouth, being generally taken in pieces the size of a bean. For the cure of discharges from wounds, it is applied to the part affected; and it is similarly used for chaps, ulcerations of the genitals, excoriations, ulcers, whether putrid, serpiginous, or of recent date, hard excrescences of the nostrils, and suppurations. It is taken also by females, in milk, for the purpose of arresting the catamenia when in excess.

The Indian lycium is distinguished from the other kinds by its colour, the lumps being black outside, and, when broken, red within, though they turn black very quickly. It is bitter and remarkably astringent, and is employed for all the purposes above mentioned, diseases of the generative organs in particular.

Detailed table of contents

CHAP. 78.

SARCOCOLLA: TWO REMEDIES.

Some authors are of opinion that sarcocolla is a tearlike gum which exudes from a kind of thorn; it is similar to powdered incense in appearance, has a sweet flavour with a slight degree of bitter, and is of the consistency of gum. Pounded in wine, it arrests defluxions, and is used as a topical application for infants more particularly. This substance too becomes black when old; the whiter it is, the more highly it is esteemed.

[Detailed table of contents](#)

CHAP. 79.

OPORICE: TWO REMEDIES.

We are indebted too to the medicinal properties of trees for one very celebrated medicament, known as “oporice.” This preparation is used for dysentery and various affections of the stomach; the following being the method of preparing it. Five quinces, seeds and all, with the same number of pomegranates, one sextarius of sorbs, a similar quantity of Syrian rhus, and half an ounce of saffron, are boiled in one congius of white grape-juice at a slow heat, till the whole mixture is reduced to the consistency of honey.

[Detailed table of contents](#)

CHAP. 80.

THE TRIXAGO, CHAMÆDRYS, CHAMÆDROPS, OR TECRIA: SIXTEEN REMEDIES,

We shall now add to these plants, certain vegetable productions to which the Greeks have given names belonging to trees, so that it would be doubtful whether they themselves are not trees as well.

(15.) The chamædrys is the same plant that in Latin is called “trixago;” some persons, however, call it “chamæ- drops,” and others “teucria.” The leaves of it are the size of those of mint, but in their colour and indentations they resemble those of the oak. According to some, the leaves are serrated, and it was these, they say, that first suggested the idea of the saw: the flower of it borders closely upon purple. This plant is gathered in rough craggy localities, when it is replete with juice; and, whether taken internally or applied topically, it is extremely efficacious for the stings of venomous serpents, diseases of the stomach, inveterate coughs, collections of phlegm in the throat, ruptures, convulsions, and pains in the sides. It diminishes the volume of the spleen, and acts as a diuretic and emmenagogue; for which reasons it is very useful in incipient dropsy, the usual dose being a handful of the sprigs boiled down to one third in three heminæ of water. Lozenges too are made of it for the above-named purposes, by bruising it in water. In combination with honey, it heals abscesses and inveterate or sordid ulcers: a wine too is prepared from it for diseases of the chest. The juice of the leaves, mixed with oil, disperses films on the eyes; it is taken also, in vinegar, for diseases of the spleen; employed as a friction, it is of a warming nature.

Detailed table of contents

CHAP. 81.

THE CHAMÆDAPHNE: FIVE REMEDIES.

The chamædaphne consists of a single diminutive stem, about a cubit in height, the limbs of it being smaller than those of the laurel. These leaves * *

* The seed, which is of a red colour, and attached to the leaves, is applied fresh for head-ache, is of a cooling nature for burning heats, and is taken for griping pains in the bowels, with wine. The juice of this plant, taken in wine, acts as an emmenagogue and diuretic; and applied as a pessary in wool, it facilitates laborious deliveries.

Detailed table of contents

CHAP. 82.

THE CHAMELÆA: SIX REMEDIES.

The leaves of the chamelæa resemble those of the olive: they are bitter, however, and odoriferous. This plant is found growing in craggy localities, and never exceeds a palm in height. It is of a purgative nature, and carries off phlegm and bile; for which purposes, the leaves are boiled with twice the quantity of wormwood, and the decoction taken with honey. The leaves, applied to ulcers, have a detergent effect. It is said, that if a person gathers it before sunrise, taking care to mention that he is gathering it for the cure of white specks in the eyes, and then wears it as an amulet, it will effect a cure: as also that, gathered in any way, it is beneficial for the eyes of beasts of burden and cattle.

Detailed table of contents

CHAP. 83.

THE CHAMÆSYCE: EIGHT REMEDIES.

The chamæsyce has leaves similar to those of the lentil, and lying close to the ground; it is found growing in dry, rocky, localities. A decoction of it in wine is remarkably useful as a liniment for improving the sight, and for dispersing cataract, cicatrizations, films, and cloudiness of the eyes. Applied in a pledget of linen, as a pessary, it allays pains in the uterus; and used topically it removes warts and excrescences of all kinds. It is very useful also for hardness of breathing.

[Detailed table of contents](#)

CHAP. 84.

THE CHAMÆCISOS: ONE REMEDY.

The chamæcissos has ears like those of wheat, with numerous leaves, and small branches, about five in number. When in blossom it might almost be taken for the white violet: the root of it is diminutive. For sciatica, the leaves of it are taken, seven days consecutively, in doses of three oboli, in two cyathi of wine: this is a very bitter potion, however.

[Detailed table of contents](#)

CHAP. 85.

THE CHAMÆLEUCE, FARFARUM, OR FARFUGIUM: ONE REMEDY.

The chamæleuce is known among us as the “farfarum” or “farfugium:” it grows on the banks of rivers, and has a leaf like that of the poplar, only larger. The root of it is burnt upon cypress charcoal, and, by the aid of a funnel, the smoke inhaled, in cases of inveterate cough.

Detailed table of contents

CHAP. 86.

THE CHAMÆPEUCE: FIVE REMEDIES. THE CHAM- CYPARISSOS: TWO
REMEDIES. THE AMPELOPRASON; SIX RE- MEDIES. THE STACHYS: ONE
REMEDY.

The chamæpeuce has a leaf which resembles that of the larch, and is useful more particularly for lumbago and pains in the back. The chamæcyparissos is a herb which, taken in wine, counteracts the venom of serpents of all kinds, and of scorpions.

The ampeloprason is found growing in vineyards; it has leaves like those of the leek, and produces offensive eructations. It is highly efficacious for the stings of serpents, and acts as an emmenagogue and diuretic. Taken in drink or applied externally, it arrests discharges of blood from the generative organs. It is prescribed also for females after delivery, and is used for bites inflicted by dogs.

The plant known as “stachys” bears a strong resemblance also to a leek, but the leaves of it are longer and more numerous. It has an agreeable smell, and in colour inclines to yellow. It promotes menstruation.

Detailed table of contents

CHAP. 87.

THE CLINOPODION, CLEONICION, ZOPYRON, OR OCIMOÏDES: THREE REMEDIES.

The clinopodion, cleonicion, zopyron, or ocimoïdes, resembles wild thyme in appearance. The stem of it is tough and ligneous, and it is a palm in height. It grows in stony soils, and the leaves are trained regularly around the stem, which resembles a bed-post in appearance. This plant is taken in drink, for convulsions, ruptures, strangury, and wounds inflicted by serpents: a decoction is also made of it, and the juice is similarly employed.

Detailed table of contents

CHAP. 88.

THE CLEMATIS CENTUNCULUS; THREE REMEDIES.

We shall now have to annex some plants, of a marvellous nature no doubt, but not so well known, reserving those of a higher reputation for the succeeding Books.

Our people give the name of “centunculus,” to a creeping plant that grows in the fields, the leaves of which bear a strong resemblance to the hoods attached to our cloaks. By the Greeks it is known as the “clematis,” Taken in astringent wine it is wonderfully effectual for arresting diarrhœa: beaten up, in doses of one denarius, in five cyathi of oxymel or of warm water, it arrests hæmorrhage, and facilitates the after-birth.

Detailed table of contents

CHAP. 89.

THE CLEMATIS ECHITES, OR LAIINE.

The Greeks have other varieties also of the clematis, one of which is known as “echites” or “lagine,” and by some as the “little scammony.” Its stems are about two Feet in height, and covered with leaves: in general appearance it is not unlike scammony, were it not that the leaves are darker and more diminutive; it is found growing invineyards and cultivated soils. It is eaten as a vegetable, with oil and salt, and acts as a laxative upon the bowels. It is taken also for dysentery, with linseed, in astringent wine. The leaves of this plant are applied with polenta for defluxions of the eyes, the part affected being first covered with a pledget of wet linen. Applied to scrofulous sores, they cause them to suppurate, and if some axle-grease is then applied, a perfect cure will be effected. They are applied also to piles, with green oil, and are good for phthisis, in combination with honey. Taken with the food, they increase the milk in nursing women, and, rubbed upon the heads of infants, they promote the rapid growth of the hair. Eaten with vinegar, they act as an aphrodisiac.

[Detailed table of contents](#)

CHAP. 90.

THE EGYPTIAN CLEMATIS, DAPHNODES, OR POLY- GONOÏDES: TWO REMEDIES.

There is another kind also, known as the “Egyptian” clematis, otherwise as “daphnoïdes” or “polygonïdes:” it has a leaf like that of the laurel, and is long and slender. Taken in vinegar, it is very useful for the stings of serpents, that of the asp in particular.

Detailed table of contents

CHAP. 91. (16.)

DIFFERENT OPINIONS ON THE DRACONTIUM.

It is Egypt more particularly that produces the clematis known as the “aron,” of which we have already made some mention when speaking of the bulbs. Respecting this plant and the dracontium, there have been considerable differences of opinion. Some writers, indeed, have maintained that they are identical, and Glaucias has made the only distinction between them in reference to the place of their growth, assuming that the dracontium is nothing else than the aron in a wild state. Some persons, again, have called the root “aron,” and the stem of the plant “dracontium:” but if the dracontium is the same as the one known to us as the “dracunculus,” it is a different plant altogether; for while the aron has a broad, black, rounded root, and considerably larger, — large enough, indeed, to fill the hand, — the dracunculus has a reddish root of a serpentine form, to which, in fact, it owes its name.

Detailed table of contents

CHAP. 92.

THE AON: THIRTEEN REMEDIES.

The Greeks themselves, in fact, have established an immense difference between these two plants, in attributing to the seed of the dracunculus certain hot, pungent properties, and a fetid odour so remarkably powerful as to be productive of abortion, while upon the aron, on the other hand, they have bestowed marvellous encomiums. As an article of food, however, they give the preference to the female plant, the male plant being of a harder nature, and more difficult to cook. It carries off, they say, all vicious humours from the chest, and powdered and taken in the form either of a potion or of an electuary, it acts as a diuretic and emmenagogue. Powdered and taken in oxymel, it is good for the stomach; and we find it stated that it is administered in ewe's milk for ulcerations of the intestines, and is sometimes cooked on hot ashes and given in oil for a cough. Some persons, again, are in the habit of boiling it in milk and administering the decoction; and it has been used also in a boiled state as a topical application for defluxions of the eyes, contusions, and affections of the tonsillary glands. * * * prescribes it with oil, as an injection for piles, and recommends it as a liniment, with honey, for freckles.

Cleophrantus has greatly extolled this plant as an antidote for poisons, and for the treatment of pleurisy and peripneumony, prepared the same way as for coughs. The seed too, pounded with olive oil or oil of roses, is used as an injection for pains in the ears. Dieuches prescribes it, mixed in bread with meal, for the cure of coughs, asthma, hardness of breathing, and purulent expectorations. Diodotus recommends it, in combination with honey, as an electuary for phthisis and diseases of the lungs, and as a topical application even for fractured bones. Applied to the sexual parts, it facilitates delivery in all kinds of animals; and the juice extracted from the root, in combination with Attic honey, disperses films upon the eyes, and diseases of the stomach. A decoction of it with honey is curative of cough; and the juice is a marvellous remedy for ulcers of every description, whether phagedænic, carcinomatous, or serpiginous, and for polypus of the nostrils. The leaves, boiled in wine and oil, are good for burns, and, taken with salt and vinegar, are strongly purgative; boiled with honey, they are useful also for sprains, and used either fresh or dried, with salt, for gout in the joints.

Hippocrates has prescribed the leaves, either fresh or dried, with honey, as a topical application for abscesses. Two drachmæ of the seed or root, in two cyathi of wine, are a sufficient dose to act as an emmenagogue, and a similar quantity will have the effect of bringing away the after-birth, in cases where it is retarded. Hippocrates used to apply the root also, for the purpose. . They say too, that in times of pestilence the employment of aron as an article of food is very beneficial. It dispels the fumes of wine; and the smoke of it burnt

drives away serpents, the asp in particular, or else stupefies them to such a degree as to reduce them to a state of torpor. These reptiles also will fly at the approach of persons whose bodies have been rubbed with a preparation of aron with oil of laurel: hence it is generally thought a good plan to administer it in red wine to persons who have been stung by serpents. Cheese, it is said, keeps remarkably well, wrapped in leaves of this plant.

Detailed table of contents

CHAP. 93.

THE DRACUNCLUS; TWO REMEDIES.

The plant which I have spoken of as the dracunculus, is taken out of the ground just when the barley is ripening, and at the moon's increase. It is quite sufficient to have this plant about one, to be safe from all serpents; and it is said, that an infusion of the larger kind taken in drink, is very useful for persons who have been stung by those reptiles: it is stated also that it arrests the catamenia when in excess, due care being taken not to let iron touch it. The juice of it too is very useful for pains in the ears.

As to the plant known to the Greeks by the name of "dracontion," I have had it pointed out to me under three different forms; the first having the leaves of the beet, with a certain proportion of stem, and a purple flower, and bearing a strong resemblance to the aron. Other persons, again, have described it as a plant with a long root, embossed to all appearance and full of knots, and consisting of three stems in all; the same parties have recommended a decoction of the leaves in vinegar, as curative of stings inflicted by serpents. The third plant that has been pointed out to me has a leaf larger than that of the cornel, and a root resembling that of the reed. This root, I have been assured, has as many knots on it as the plant is years old, the leaves, too, being as many in number. The plant is recommended also for the stings of serpents, administered either in wine or in water.

Detailed table of contents

CHAP. 94.

THE ARISAXOS: THREE REMEDIES.

There is a plant also called the “arisaros,” which grows in Egypt, and is similar to the aron in appearance, only that it is more diminutive, and has smaller leaves; the root too is smaller, though fully as large as a good-sized olive. The white arisaros throws out two stems, the other kind only one. They are curative, both of them, of running ulcers and burns, and are used as an injection for fistulas. The leaves, boiled in water, and then beaten up with the addition of oil of roses, arrest the growth of corrosive ulcers. But there is one very marvellous fact connected with this plant — it is quite sufficient to touch the sexual parts of any female animal with it to cause its instantaneous death.

Detailed table of contents

CHAP. 95.

THE MILLEFOIJUM OR MYRIOPHYLLON; SEVEN REMEDIES.

The myriophyllon, by our people known as the “mille- folium” has a tender stem, somewhat similar to fennel-giant ill appearance, with vast numbers of leaves, to which circumstance it is indebted for its name. It grows in marshy localities, and is remarkably useful for the treatment of wounds. It is taken in vinegar for strangury, affections of the bladder, asthma, and falls with violence; it is extremely efficacious also for tooth-ache.

In Etruria, the same name is given to a small meadow- plant, provided with leaves at the sides, like hairs, and particularly useful for wounds. The people of that country say that, applied with axle-grease, it will knit together and unite the tendons of oxen, when they have been accidentally severed by the plough-share.

Detailed table of contents

CHAP. 96.

THE PSEUDOBUNION: FOUR REMEDIES

The pseudobunion has the leaves of the turnip, and grows in a shrub-like form, about a palm in height; the most esteemed being that of Crete. For gripings of the bowels, strangury, and pains of the thoracic organs, some five or six sprigs of it are administered in drink.

[Detailed table of contents](#)

CHAP. 97.

THE MYRRHIS, MYRZA, OR MYRIRHA: SEVEN REMEDIES.

The myrrhis, otherwise known as the myriza or myrrha, bears a strong resemblance to hemlock in the stem, leaves, and blossom, only that it is smaller and more slender: it is by no means unpleasant to the palate. Taken with wine, it acts as an emmenagogue, and facilitates parturition: they say too that in times of pestilence it is very wholesome, taken in drink. It is very useful also for phthisis, administered in broth. It sharpens the appetite, and neutralizes the venom of the phalangium. The juice of this plant, after it has been macerated some three days in water, is curative of ulcers of the face and head.

Detailed table of contents

CHAP. 98.

THE ONOBRYCHIS: THREE REMEDIES.

The onobrychis has leaves like those of the lentil, only somewhat longer; the blossom is red, and the root small and slender. It is found growing in the vicinity of springs. Dried and reduced to powder, and sprinkled in white wine, it is curative of strangury, and arrests looseness of the bowels. The juice of it, used as a friction with oil, acts as a sudorific.

CHAP. 99. (17.)

CORACESTA AND CALLICIA.

While I am treating of plants of a marvellous nature, I am induced to make some mention of certain magical plants — for what, in fact, can there be more marvellous than they? The first who descanted upon this subject in our part of the world were Pythagoras and Democritus, who have adopted the accounts given by the Magi. Coracesta and callicia, according to Pythagoras, are plants which congeals water. I find no mention made of them, however, by any other author, and he himself gives no further particulars relative to them.

Detailed table of contents

CHAP. 100.

THE MINSAS OR CORINTHIA: ONE REMEDY.

Pythagoras gives the name of minsas too, or corinthia, to another plant; a decoction of which, used as a fomentation, will effect an instantaneous cure of stings inflicted by serpents, according to him. He adds too, that if this decoction is poured upon the grass, and a person happens to tread upon it, or if the body should chance to be sprinkled with it, the result is fatal beyond all remedy; so monstrously malignant are the venomous properties of this plant, except as neutralizing other kinds of poison.

[Detailed table of contents](#)

CHAP. 101.

THE APROXIS: SIX REMEDIES.

Pythagoras makes mention, too, of a plant called aproxis, the root of which takes fire at a distance, like naphtha, of which we have made some mention, when speaking of the marvellous productions of the earth. He says too, that if the human body happens to be attacked by any disease while the cabbage is in blossom, the person, although he may have been perfectly cured, will be sensible of a recurrence of the symptoms, every time that plant comes into blossom; a peculiarity which he attributes to it in common with wheat, hemlock, and the violet.

I am not ignorant, however, that the work of his from which I have just quoted is ascribed to the physician Cleemporus by some, though antiquity and the unbroken current of tradition concur in claiming it for Pythagoras. It is quite enough, however, to say in favour of a book, that the author has deemed the results of his labours worthy to be published under the name of so great a man. And yet who can believe that Cleemporus would do this, seeing that he has not hesitated to publish other works under his own name?

Detailed table of contents

CHAP. 102.

THE AGLAOPHOTIS OR MARMARITIS. THE ACHLE- MENIS OR HIPPOPHOBAS.

THE THEOBROTION OR SEMNION. THE ADAMANTIS. THE ARIANIS. THE
THERIONARCA. THE, ÆTHIOPIS OR MEROIS. THE OPHIUSA. THE THALASSEGLE
OR POTAM- AUGIS. THE THEANGELIS. THE GELOTOPHYLLIS. THE HESTI-
ATORIS OR PROTOMEDIA. THE CASIGNETES OR DIONYSOYNYPHAS. THE
HELIANTHES OR HELIOCALLIS. HERMESIAS. THE ÆSCHY- NOMENE. THE
CROCIS. THE GENOTHERIS. THE ANACAMPIS- EROS.

As to Democritus, there can be no doubt that the work called “Chirocmeta” belongs to him. How very much more marvellous too are the accounts given in this book by the philosopher who, next to Pythagoras, has acquired the most intimate knowledge of the learning of the Magi! According to him, the plant aglaophotis, which owes its name to the admiration in which its beauteous tints are held by man, is found growing among the marble quarries of Arabia, on the side of Persia, a circumstance which has given it the additional name of “marmaritis.” By means of this plant, he says, the Magi can summon the deities into their presence when they please.

The achæmenis, he says, a plant the colour of amber, and destitute of leaves, grows in the country of the Tradastili, an Indian race. The root of it, divided into lozenges and taken in wine in the day time, torments the guilty to such a degree during the night by the various forms of avenging deities presented to the imagination, as to extort from them a confession of their crimes. He gives it the name also of “hippophobas,” it being an especial object of terror to mares.

The theobrotion is a plant found at a distance of thirty schœnis from the river Choaspes; it represents the varied tints of the peacock, and the odour of it is remarkably fine. The kings of Persia, he says, are in the habit of taking it in their food or drink, for all maladies of the body, and derangements of the mind. It has the additional name of semnion, from the use thus made of it by majesty.

He next tells us of the adamantis, a plant grown in Armenia and Cappadocia: presented to a lion, he says, the beast will fall upon its back, and drop its jaws. Its name originates in the fact that it is impossible to bruise it. The arianis, he says, is found in the country of the Ariani; it is of a fiery colour, and is gathered when the sun is in Leo. Wood rubbed with oil will take fire on coming in contact with this plant. The therionarca, he tells us, grows in Cappadocia and Mysia; it has the effect of striking wild beasts of all kinds with a torpor which can only be dispelled by sprinkling them with the urine of the hyæna. He speaks too of the æthiopis, a plant which grows in Meroë; for which reason it is also known as the “meroïs.” In leaf it resembles the lettuce, and, taken with honied wine, it is very good for dropsy. The ophiusa, which is found in Elephantine, an island also of Æthiopia, is a plant of a livid colour,

and hideous to the sight. Taken by a person in drink, he says, it inspires such a horror of serpents, which his imagination continually represents as menacing him, that he commits suicide at last; hence it is that persons guilty of sacrilege are compelled to drink an infusion of it. Palm wine, he tells us, is the only thing that neutralizes its effects.

The thalassægle he speaks of as being found on the banks of the river Indus, from which circumstance it is also known as the potamaugis. Taken in drink it produces a delirium, which presents to the fancy visions of a most extraordinary nature. The theangelis, he says, grows upon Mount Libanus in Syria, upon the chain of mountains called Dicte in Crete, and at Babylon and Susa in Persis. An infusion of it in drink, imparts powers of divination to the Magi. The gelotophyllis too, is a plant found in Bactriana, and on the banks of the Borysthenes. Taken internally with myrrh and wine, all sorts of visionary forms present themselves, and excite the most immoderate laughter, which can only be put an end to by taking kernels of the pine-nut, with pepper and honey, in palm wine.

The hestiatoris, he tells us, is a Persian plant, so called from its promotion of gaiety and good fellowship at carousals. Another name for it is protomedia, because those who eat of it will gain the highest place in the royal favour. The casignetes too, we learn, is so called, because it grows only among plants of its own kind, and is never found in company with any other; another name given to it is "dionysonymphas," from the circumstance of its being remarkably well adapted to the nature of wine. Helianthes is the name he gives to a plant found in the regions of Themiscyra and the mountainous parts of maritime Cilicia, with leaves like those of myrtle. This plant is boiled up with lion's fat, saffron and palm wine being added; the Magi, he tells us, and Persian monarchs are in the habit of anointing the body with the preparation, to add to its graceful appearance: he states also, that for this reason it has the additional name of "heliocallis." What the same author calls "hermesias," has the singular virtue of ensuring the procreation of issue, both beautiful as well as good. It is not a plant, however, but a composition made of kernels of pine nuts, pounded with honey, myrrh, saffron, and palm wine, to which theobrotium and milk are then added. He also recommends those who wish to become parents to drink this mixture, and says, that females should take it immediately after conception, and during pregnancy. If this is done, he says, the infant will be sure to be endowed with the highest qualities, both in mind and body. In addition to what has here been stated, Democritus gives the various names by which all these plants are known to the Magi.

Apollodorus, one of the followers of Democritus, has added to this list the herb æschynomene, so called from the shrinking of its leaves at the approach of the hand; and another called "crocis," the touch of which is fatal to the phalangium. Crateuas, also, speaks of the œnotheris, an infusion of which in wine, sprinkled upon them, has the effect of taming all kind of animals, however wild. A celebrated grammarian, who lived but very recently, has

described the anacampseros, the very touch of which recalls former love, even though hatred should have succeeded in its place. It will be quite sufficient for the present to have said thus much in reference to the remarkable virtues attributed to certain plants by the Magi; as we shall have occasion to revert to this subject in a more appropriate place.

Detailed table of contents

CHAP. 103. (18.)

THE ERIPIHA.

Many authors have made mention of the eriphia, a plant which contains a kind of beetle in its hollow stem. This beetle is continually ascending the interior of the stalk, and as often descending, while it emits a sound like the cry of a kid; a circumstance to which the plant is indebted for its name. There is nothing in existence, they say, more beneficial to the voice.

Detailed table of contents

CHAP. 104.

THE WOOL PLANT: ONE REMEDY. THE, LACTORIS: ONE REMEDY. THE
MILITARIS: ONE REMEDY.

The wool plant, given to sheep fasting, greatly increases the milk. The plant commonly called lactoris, is equally well known: it is full of a milky juice, the taste of which produces vomiting. Some persons say that this is identical with, while others say that it only resembles, the plant known as “mili- tris.” from the fact that, applied with oil, it will effect the cure. within five days, of any wound that has been inflicted with iron.

Detailed table of contents

CHAP. 105.

THE STRATIOTES: FIVE- REMEDIES.

The Greeks speak in high terms also of the stratiotes, though that is a plant which grows in Egypt only, and during the inundations of the river Nilus. It is similar in appearance to the aïon, except that the leaves are larger. It is of a remarkably cooling nature, and, applied with vinegar, it heals wounds, as well as erysipelas and suppurations. Taken in drink with male fankincense, it is marvellously useful for discharges of blood from the kidneys.

Detailed table of contents

CHAP. 106. (19.)

A PLANT GROWING ON THE HEAD OF A STATUE: ONE REMEDY.

It is asserted also, that a plant growing on the head of a statue, gathered in the lappet of any one of the garments, and then attached with a red string to the neck, is an instantaneous cure for head-ache.

Detailed table of contents

CHAP. 107.

A PLANT GROWING ON THE BANKS OF A RIVER: ONE REMEDY.

Any plant that is gathered before sunrise on the banks of a stream or river, due care being taken that no one sees it gathered, attached to the left arm without the patient knowing what it is, will cure a tertian fever, they say.

Detailed table of contents

CHAP. 108.

THE HERB CALLED LINGUA: ONE REMEDY.

There is a herb called “lingua,” which grows in the vicinity of fountains. The root of it, reduced to ashes and beaten up with hog’s lard — the hog, they say, must have been black and barren — will cure alopecia, the head being rubbed with it in the sun.

Detailed table of contents

CHAP. 109.

PLANTS THAT TAKE ROOT IN A SIEVE: ONE REMEDY.

Plants that take root in a sieve that has been thrown in a hedge-row, if gathered and worn upon the person by a pregnant woman, will facilitate delivery.

Detailed table of contents

CHAP. 110.

PLANTS GROWING UPON DUNG HILLS: ONE REMEDY.

A plant that has been grown upon a dungheap in a field, is a very efficacious remedy, taken in water, for quinzy.

Detailed table of contents

CHAP. 111.

PLANTS THAT HAVE BEEN MOISTENED WITH THE URINE OF A DOG: ONE
REMEDY.

A plant upon which a dog has watered, torn up by the roots, and not touched with iron, is a very speedy cure for sprains.

Detailed table of contents

CHAP. 112.

THE RODARUM: THREE REMEDIES.

We have already made mention of the rumpotinus, when speaking of the vine-growing trees. Near the tree, when not accompanied by the vine, there grows a plant, known to the Gauls as the “rodarum.” It has a knotted stem like the branch of a fig-tree, and the leaves, which are very similar to those of the nettle, are white in the middle, though in process of time they become red all over. The blossom of it is of a silvery hue. Beaten up with stale axle-grease, due care being taken not to touch it with iron, this plant is extremely useful for tumours, inflammations, and gatherings; the patient, however, on being anointed with it must spit three times on the right side. They say too, that as a remedy it is still more efficacious, if three persons of three different nations rub the right side of the body with it.

Detailed table of contents

CHAP. 113.

THE PLANT CALLED IMPIA: TWO REMEDIES.

The plant called “impia” is white, resembling rosemary in appearance. It is clothed with leaves like a thyrsus, and is terminated by a head, from which a number of small branches protrude, terminated, all of them, in a similar manner. It is this peculiar conformation that has procured for it the name of “impia,” from the progeny thus surmounting the parent. Some persons, however, are of opinion that it is so called because no animal will touch it. Bruised between two stones it yields an effervescent juice, which, in combination with wine and milk, is remarkably efficacious for quinzey.

There is a marvellous property attributed to this plant, to the effect that persons who have once tasted it will never be attacked by quinzey; for which reason it is given to swine: those among them, however, which refuse to take it will be sure to die of that disease. Some persons too are of opinion that if slips of it are put into a bird’s nest, they will effectually prevent the young birds from choking themselves by eating too voraciously.

Detailed table of contents

CHAP. 114.

THE PLANT CALLED VENUS' COMB: ONE REMEDY.

From its resemblance to a comb, they give the name of “Venus’ comb” to a certain plant, the root of which, bruised with mallows, extracts all foreign substances from the human body.

[Detailed table of contents](#)

CHAP. 115.

THE EXEDUNM. THE PLANT CALLED NOTIA: TWO REMEDIES.

The plant called “exedum” is curative of lethargy. The herbaceous plant called “notia,” which is used by curriers for dyeing leather a bright, cheerful colour, and known by them under various names — is curative of cancerous ulcers; I find it also stated that, taken in wine or in oxycrate, it is extremely efficacious for stings inflicted by scorpions.

Detailed table of contents

CHAP. 116.

THE PHILANTHROPOS: ONE REMEDY. THE LAPP CANARIA: TWO REMEDIES.

The Greeks wittily give the name of “philanthropos” to a certain plant, because it attaches itself to articles of dress. A chaplet made of this plant has the effect of relieving headache.

As to the plant known as the “lappa canaria,” beaten up in wine with plantago and millefolium, it effects the cure of carcinomatous sores, the application being removed at the end of three days. Taken out of the ground without the aid of iron, and thrown into their wash, or given to them wine and milk, it cures diseases in swine. Some persons add, however, that the person, as he takes it up, must say— “This is the plant argemon, a remedy discovered by Minerva for such swine as shall taste thereof.”

Detailed table of contents

CHAP. 117.

TORDYLON OR SYREON: THREE REMEDIES.

Tordylon is, according to some authorities, the seed of sili, while according to others it is a distinct plant, as known also as “syreon.” I find no particulars relative to it, except that it grows upon mountains, and that the ashes of it, taken in drink, act as an emmenagogue and facilitate expectoration. It is stated also, that for this last purpose the root is even more efficacious than the stem; that the juice of it, taken in doses of three oboli, cures diseases of the kidneys; and that the root is used as an ingredient for emollient plasters.

[Detailed table of contents](#)

CHAP. 118.

GRAMEN: SEVENTEEN REMEDIES.

Gramen is of all herbaceous productions the most common. As it creeps along the ground it throws out jointed stems, from the joints of which, as well as from the extremity of the stem, fresh roots are put forth every here and there. In all other parts of the world the leaves of it are tapering, and come to a point; but upon Mount Parnassus they resemble the leaves of the ivy, the plant throwing out a greater number of stems than elsewhere, and bearing a blossom that is white and odoriferous. There is no vegetable production that is more grateful to beasts of burden than this, whether in a green state or whether dried and made into hay, in which last case it is sprinkled with water when given to them. It is said that on Mount Parnassus a juice is extracted from it, which is very abundant and of a sweet flavour.

In other parts of the world, instead of this juice a decoction of it is employed for closing wounds; an effect equally produced by the plant itself, which is beaten up for the purpose and attached to the part affected, thereby preventing inflammation. To the decoction wine and honey are added, and in some cases, frankincense, pepper, and myrrh, in the proportion of one third of each ingredient; after which it is boiled again in a copper vessel, when required for tooth-ache or diffluxions of the eyes. A decoction of the roots, in wine, is curative of griping pains in the bowels, strangury, and ulcerations of the bladder, and it disperses calculi. The seed is still more powerful as a diuretic, arrests looseness and vomiting, and is particularly useful for wounds inflicted by dragons. There are some authorities which give the following prescription for the cure of scrofulous sores and inflamed tumours: — From one, two, or three stems, as many as nine joints must be removed, which must then be wrapped in black wool with the grease in it. The party who gathers them must do so fasting, and must then go, in the same state, to the patient's house while he is from home. When the patient comes in, the other must say to him three times, "I come fasting to bring a remedy to a fasting man;" and must then attach the amulet to his person, repeating the same ceremony three consecutive days. The variety of this plant which has seven joints is considered a most excellent amulet for the cure of head-ache. For excruciating pains in the bladder, some recommend a decoction of gramen, boiled down in wine to one half, to be taken immediately after the bath.

CHAP. 119.

DACTYLOS; FIVE REMEDIES.

There are some authorities who mention three varieties of the pointed gramen. That which has at the extremity five points at the utmost, is called “dactylos.” Twisting these points together, persons introduce them into the nostrils and then withdraw them, with the view of preventing hæmorrhage. The second kind, which resembles aizoön, is employed with axle-grease for whitlows and hangnails, and for fleshy excrescences upon the nails: this also is called “dactylos,” because it is so useful as a remedy for diseases of the fingers.

The third kind, which is also known as “dactylos,” is more diminutive, and is found growing upon walls or tiles. It has certain caustic properties, and arrests the progress of serpiginous ulcers. By placing a wreath of gramen round the head, bleeding at the nose is stopped. In Babylonia, it is said, the gramen which grows by the wayside is fatal to camels.

[Detailed table of contents](#)

CHAP. 120.

FENUGREEK OR SILICIA: THIRTY-ONE REMEDIES.

Nor is fenugreek held in less esteem. By some it is known as “telis,” by others as “carphos,” and by others again as “buceras,” or “ægoceras,” the produce of it bearing some resemblance to horns. Among us it is known as “silicia.” The mode of sowing it we have already described on the appropriate occasion. Its properties are desiccative, emollient, and resolvent. A decoction of it is useful for many female maladies, indurations for instance, tumours, and contractions of the uterus; in all which cases it is employed as a fomentation or used for a sitting-bath: it is serviceable also as an injection. It removes cutaneous eruptions on the face; and a decoction of it, applied topically with nitre or vinegar, cures diseases of the spleen or liver. In cases of difficult labour, Diocles recommends the seed pounded, in doses of one acetabulum, mixed with boiled must. After taking one third of the mixture, the patient must use a warm bath, and then, while in a perspiration, she must take another third, and, immediately after leaving the bath, the remainder — this, he says, will prove a most effectual means of obtaining relief.

The same authority recommends fenugreek boiled, with barley or linseed, in hydromel, as a pessary for violent pains in the uterus: he prescribes it also as an external application for the lower regions of the abdomen. He speaks also of treating leprous sores and freckles with a mixture composed of equal proportions of sulphur and meal of fenugreek, recommending it to be applied repeatedly in the course of the day, due care being taken not to rub the part affected.

For the cure of leprosy, Theodorus prescribes a mixture of fenugreek, and one fourth part of cleaned nasturtium, the whole to be steeped in the strongest vinegar. Damion used to give a potion by way of emmenagogue, consisting of half an acetabulum of fenugreek seed in nine cyathi of boiled must and water. There is no doubt too, that a decoction of it is remarkably useful for diseases of the uterus and for ulcerations of the intestines, and that the seed is beneficial for affections of the joints and chest. Boiled with mallows and then taken in honied wine, fenugreek is extolled in the highest terms, as serviceable for affections of the uterus and intestines. Indeed, the very steam that arises from the decoction may be productive of considerable benefit. A decoction too of fenugreek seed is a corrective of the rank odours of the armpits. Meal of fenugreek, with wine and nitre, speedily removes ring-worm and dandriff of the head; and a decoction of it in hydromel, with the addition of axle-grease, is used for the cure of diseases of the generative organs, inflamed tumours, imposthumes of the parotid glands, gout in the Feet and hands, maladies of the joints, and denudations of the bones. Kneaded with vinegar, it effects the cure of sprains, and, boiled in oxymel only, it is used as a liniment

for affections of the spleen. Kneaded with wine, it acts as a detergent upon carcinomatous sores; after which, applied with honey, it effects a perfect cure. A pottage too is made of this meal, which is taken for ulcerations of the chest and chronic coughs; it is kept boiling a considerable time, in order to remove the bitterness, after which honey is added.

We shall now proceed to speak of the plants which have gained a higher degree of reputation.

SUMMARY. — Remedies, narratives, and observations, eleven hundred and seventy-six.

ROMAN ATUTHORS QUOTED. — C. Valgius, Pompeius Lenæus, Sextius Niger who wrote in Greek, Julius Bassus who wrote in Greek, Antonius Castor, Cornelius Celsus.

FOREIGN AUTHORS QUOTED. — Theophrastus, Apollodorus, Democritus, Orpheus, Pythagoras, Mago, Menander who wrote the “Biochresta,” Nicander, Homer, Hesiod, Musæus, Sophocles, Anaxilaüs.

MEDICAL AUTHORS QUOTED. — Mnesitheus, Callimachus, Phantias the physician, Timaristus, Simus, Hippocrates, Chrysippus, Diocles, Ophelion, Heraclides, Hicesius, Dionysius, Apollodorus of Citium, Apollodorus of Tarentum, Praxagoras, Plistonius, Medius, Dieuches, Cleophrantus, Philistion, Asclepiades, Crateuas, Petronius Diodotus, Iollas, Erasistratus, Diagoras, Andreas, Mnesides, Epicharmus, Damion, Sosimenes, Tlepolemus, Metrodorus, Solon, Lycus, Olympias of Thebes, Philinus, Petrichus, Micton, Glaucias, Xenocrates.

BOOK XXV. THE NATURAL HISTORY OF WILD PLANT

Detailed table of contents

CHAP. 1. (1.)

WHEN THE WILD PLANTS WERE FIRST BROUGHT INTO USE.

THE more highly esteemed plants of which I am now about to speak, and which are produced by the earth for medicinal purposes solely, inspire me with admiration of the industry and laborious research displayed by the ancients. Indeed there is nothing that they have not tested by experiment or left untried; no discovery of theirs which they have not disclosed, or which they have not been desirous to leave for the benefit of posterity. We, on the contrary, at the present day, make it our object to conceal and suppress the results of our labours, and to defraud our fellow-men of blessings even which have been purchased by others. For true it is, beyond all doubt, that those who have gained any trifling accession of knowledge, keep it to themselves, and envy the enjoyment of it by others; to leave mankind uninstructed being looked upon as the high prerogative of learning. So far is it from being the habit with them to enter upon new fields of discovery, with the view of benefitting mankind at large, that for this long time past it has been the greatest effort of the ingenuity of each, to keep to himself the successful results of the experience of former ages, and so bury them for ever!

And, yet, by Hercules! a single invention before now has elevated men to the rank of gods; and how many an individual has had his name immortalized in being bestowed upon some plant which he was the first to discover, thanks to the gratitude which prompted a succeeding age to make some adequate return! If it had been expended solely upon the plants which are grown to please the eye, or which invite us by their nutrimental properties, this laborious research on the part of the ancients would not have been so surprising; but in addition to this, we find them climbing by devious tracts to the very summit of mountains, penetrating to the very heart of wilds and deserts, and searching into every vein and fibre of the earth-and all this, to discover the hidden virtues of every root, the properties of the leaf of every plant, and the various purposes to which they might be applied; converting thereby those vegetable productions, which the very beasts of the field refuse to touch, into so many instruments for our welfare.

Detailed table of contents

CHAP. 2. (2.)

THE LATIN AUTHORS WHO HAVE WRITTEN UPON THESE PLANTS.

This subject has not been treated of by the writers in our own language so extensively as it deserves, eager as they have proved themselves to make enquiry into everything that is either meritorious or profitable. M. Cato, that great master in all useful knowledge, was the first, and, for a long time, the only author who treated of this branch of learning; and briefly as he has touched upon it, he has not omitted to make some mention of the remedial treatment of cattle. After him, another illustrious personage, C. Valgius, a man distinguished for his erudition, commenced a treatise upon the same subject, which he dedicated to the late Emperor Augustus, but left unfinished. At the beginning of his preface, replete as it is with a spirit of piety, he expresses a hope that the majestic sway of that prince may ever prove a most efficient remedy for all the evils to which mankind are exposed.

Detailed table of contents

CHAP. 3.

AT WHAT PERIOD THE ROMANS ACQUIRED SOME KNOW-LEDGE OF THIS SUBJECT.

The only person among us, at least so far as I have been able to ascertain, who had treated of this subject before the time of Valgius, was Pompeius Lenæus, the freedman of Pompeius Magnus; and it was in his day, I find, that this branch of knowledge first began to be cultivated among us. Mithridates, the most powerful monarch of that period, and who was finally conquered by Pompeius, is generally thought to have been a more zealous promoter of discoveries for the benefit of mankind, than any of his predecessors — a fact evinced not only by many positive proofs, but by universal report as well. It was he who first thought, the proper precautions being duly taken, of drinking poison every day; it being his object, by becoming habituated to it, to neutralize its dangerous effects. This prince was the first discoverer too of the various kinds of antidotes, one of which, indeed, still retains his name; and it is generally supposed that he was the first to employ the blood of the ducks of Pontus as an ingredient in antidotes, from the circumstance that they derive their nutriment from poisons.

It was to Mithridates that Asclepiades, that celebrated physician, dedicated his works, still extant, and sent them, as a substitute for his own personal attendance, when requested by that monarch to leave Rome and reside at his court. It is a well-known fact, that this prince was the only person that was ever able to converse in so many as two-and-twenty languages, and that, during the whole fifty-six years of his reign, he never required the services of an interpreter when conversing with any individuals of the numerous nations that were subject to his sway.

Among the other gifts of extraordinary genius with which he was endowed, Mithridates displayed a peculiar fondness for enquiries into the medical arts; and gathering items of information from all his subjects, extended, as they were, over a large proportion of the world, it was his habit to make copies of their communications, and to take notes of the results which upon experiment had been produced. These memoranda, which he kept in his private cabinet, fell into the hands of Pompeius, when he took possession of the royal treasures; who at once commissioned his freedman, Lenæus the grammarian, to translate them into the Latin language: the result of which was, that his victory was equally conducive to the benefit of the republic and of mankind at large.

CHAP. 4.

GREEK AUTHORS WHO HAVE DELINEATED THE PLANTS IN COLOURS.

In addition to these, there are some Greek writers who have treated of this subject, and who have been already mentioned on the appropriate occasions. Among them, Crateuas, Dionysius, and Metrodorus, adopted a very attractive method of description, though one which has done little more than prove the remarkable difficulties which attended it. It was their plan to delineate the various plants in colours, and then to add in writing a description of the properties which they possessed. Pictures, however, are very apt to mislead, and more particularly where such a number of tints is required, for the imitation of nature with any success; in addition to which, the diversity of copyists from the original paintings, and their comparative degrees of skill, add very considerably to the chances of losing the necessary degree of resemblance to the originals. And then, besides, it is not sufficient to delineate a plant as it appears at one period only, as it presents a different appearance at each of the four seasons of the year.

Detailed table of contents

CHAP. 5.

THE FIRST GREEK AUTHORS WHO WROTE UPON PLANTS.

Hence it is that other writers have confined themselves to a verbal description of the plants, indeed some of them have not so much as described them even, but have contented themselves for the most part with a bare recital of their names, considering it sufficient if they pointed out their virtues and properties to such as might feel inclined to make further enquiries into the subject. Nor is this a kind of knowledge by any means difficult to obtain; at all events, so far as regards myself, with the exception of a very few, it has been my good fortune to examine them all, aided by the scientific researches of Antonius Castor, who in our time enjoyed the highest reputation for an intimate acquaintance with this branch of knowledge. I had the opportunity of visiting his garden, in which, though he had passed his hundredth year, he cultivated vast numbers of plants with the greatest care. Though he had reached this great age, he had never experienced any bodily ailment, and neither his memory nor his natural vigour had been the least impaired by the lapse of time.

There was nothing more highly admired than an intimate knowledge of plants, in ancient times. It is long since the means were discovered of calculating before-hand, not only the day or the night, but the very hour even at which an eclipse of the sun or moon is to take place; and yet the greater part of the lower classes still remain firmly persuaded that these phenomena are brought about by compulsion, through the agency of herbs and enchantments, and that the knowledge of this art is confined almost exclusively to females. What country, in fact, is not filled with the fabulous stories about Medea of Colchis and other sorceresses, the Italian Circe in particular, who has been elevated to the rank of a divinity even? It is with reference to her, I am of opinion, that Æschylus, one of the most ancient of the poets, asserts that Italy is covered with plants endowed with potent effects, and that many writers say the same of Circeii, the place of her abode. Another great proof too that such is the case, is the fact, that the nation of the Marsi, descendants of a son of Circe, are well known still to possess the art of taming serpents.

Homer, that great parent of the learning and traditions of antiquity, while extolling the fame of Circe in many other respects, assigns to Egypt the glory of having first discovered the properties of plants, and that; too at a time when the portion of that country which is now watered by the river Nilus was not in existence, having been formed at a more recent period by the alluvion of that river. At all events, he states that numerous Egyptian plants were sent to the Helena of his story, by the wife of the king of that country, together with the celebrated nepenthes, which ensured oblivion of all sorrows and forgetfulness of the past, a potion which Helena was to administer to all mortals. The first

person, however, of whom the remembrance has come down to us, as having treated with any degree of exactness on the subject of plants, is Orpheus; and next to him Musæus and Hesiod, of whose admiration of the plant called polium we have already made some mention on previous occasions. Orpheus and Hesiod too we find speaking in high terms of the efficacy of fumigations. Homer also speaks of several other plants by name, of which we shall have occasion to make further mention in their appropriate places.

In later times again, Pythagoras, that celebrated philosopher, was the first to write a treatise on the properties of plants, a work in which he attributes the origin and discovery of them to Apollo, Æsculapius, and the immortal gods in general. Democritus too, composed a similar work. Both of these philosophers had visited the magicians of Persia, Arabia, Æthiopia, and Egypt, and so astounded were the ancients at their recitals, as to learn to make assertions which transcend all belief. Xanthus, the author of some historical works, tells us, in the first of them, that a young dragon was restored to life by its parent through the agency of a plant to which he gives the name of “ballis,” and that one Tylon, who had been killed by a dragon, was restored to life and health by similar means. Juba too assures us that in Arabia a man was resuscitated by the agency of a certain plant. Democritus has asserted — and Theophrastus believes it — that there is a certain herb in existence, which, upon being carried thither by a bird, the name of which we have already given, has the effect, by the contact solely, of instantaneously drawing a wedge from a tree, when driven home by the shepherds into the wood.

These marvels, incredible as they are, excite our admiration nevertheless, and extort from us the admission that, making all due allowance, there is much in them that is based on truth. Hence it is too that I find it the opinion of most writers, that there is nothing which cannot be effected by the agency of plants, but that the properties of by far the greater part of them remain as yet unknown. In the number of these was Herophilus, a celebrated physician, a saying of whose is reported, to the effect that some plants may possibly exercise a beneficial influence, if only trodden under foot. Be this as it may, it has been remarked more than once, that wounds and maladies are sometimes inflamed upon the sudden approach of persons who have been journeying on foot.

[Detailed table of contents](#)

CHAP. 6.

WHY A FEW OF THE PLANTS ONLY HAVE BEEN USED MEDICINALLY. PLANTS, THE MEDICINAL PROPERTIES OF WHICH HAVE BEEN MIRACULOUSLY DISCOVERED. THE CYNORRHODOS: TWO REMEDIES. THE PLANT CALLED DRACUNCULUS: ONE REMEDY. THE BRITANNICA: FIVE REMEDIES.

Such was the state of medical knowledge in ancient times, wholly concealed as it was in the language of the Greeks. But the main reason why the medicinal properties of most plants remain still unknown, is the fact that they have been tested solely by rustics and illiterate people, such being the only class of persons that live in the midst of them: in addition to which, so vast is the multitude of medical men always at hand, that the public are careless of making any enquiries about them. Indeed, many of those plants, the medicinal properties of which have been discovered, are still destitute of names — such, for instance, as the one which we mentioned when speaking of the cultivation of grain, and which we know for certain will have the effect of keeping birds away from the crops, if buried at the four corners of the field.

But the most disgraceful cause of all, why so few simples are known, is the fact that those even who are acquainted with them are unwilling to impart their knowledge; as though, forsooth, they should lose for ever anything that they might think fit to communicate to others! Added to all this, there is no well-ascertained method to guide us to the acquisition of this kind of knowledge; for, as to the discoveries that have been made already, they have been due, some of them, to mere accident, and others again, to say the truth, to the interposition of the Deity.

Down to our own times, the bite of the mad dog, the symptoms of which are a dread of water and an aversion to every kind of beverage, was incurable; and it was only recently that the mother of a soldier who was serving in the prætorian guard, received a warning in a dream, to send her son the root of the wild rose, known as the cynorrhodos, a plant the beauty of which had attracted her attention in a shrubbery the day before, and to request him to drink the extract of it. The army was then serving in Lacetania, the part of Spain which lies nearest to Italy; and it so happened that the soldier, having been bitten by a dog, was just beginning to manifest a horror of water when his mother's letter reached him, in which she entreated him to obey the words of this divine warning. He accordingly complied with Her request, and, against all hope or expectation, his life was saved; a result which has been experienced by all who have since availed themselves of the same resource. Before this, the cynorrhodos had been only recommended by writers for one medicinal purpose; the spongy excrescences, they say, which grow in the midst of its thorns, reduced to ashes and mixed with honey, will make the hair grow again when it has been lost by alopecia. I know too, for a fact, that in the same province there was lately discovered in the land belonging to a person

with whom I was staying, a stalked plant, the name given to which was dracunculus. This plant, about an inch in thickness, and spotted with various colours, like a viper's skin, was generally reported to be an effectual preservative against the sting of all kinds of serpents. I should remark, however, that it is a different plant from the one of the same name of which mention has been made in the preceding Book, having altogether another shape and appearance. There is also another marvellous property belonging to it: in spring, when the serpents begin to cast their slough, it shoots up from the ground to the height of about a couple of Feet, and again, when they retire for the winter it conceals itself within the earth, nor is there a serpent to be seen so long as it remains out of sight. Even if this plant did nothing else but warn us of impending danger, and tell us when to be on our guard, it could not be looked upon otherwise than as a beneficent provision made by Nature in our behalves.

(3.) It is not, however, the animals only that are endowed with certain baneful and noxious properties, but, sometimes, waters even, and localities as well. Upon one occasion, in his German campaign, Germanicus Cæsar had pitched his camp beyond the river Rhenus; the only fresh water to be obtained being that of a single spring in the vicinity of the sea-shore. It was found, however, that within two years the habitual use of this water was productive of loss of the teeth and a total relaxation of the joints of the knees: the names given to these maladies, by medical men, were “stomacace” and “sceloturbe.” A remedy for them was discovered, however, in the plant known as the “britannica,” which is good, not only for diseases of the sinews and mouth, but for quinzey also, and injuries inflicted by serpents. This plant has dark oblong leaves and a swarthy root: the name given to the flower of it is “vibones,” and if it is gathered and eaten before thunder has been heard, it will ensure safety in every respect. The Frisii, a nation then on terms of friendship with us, and within whose territories the Roman army was encamped, pointed out this plant to our soldiers: the name given to it, however, rather surprises me, though possibly it may have been so called because the shores of Britannia are in the vicinity, and only separated by the ocean. At all events, it was not called by this name from the fact of its growing there in any great abundance, that is quite certain, for at the time I am speaking of, Britannia was still independent.

Detailed table of contents

CHAP. 7.

WHAT DISEASES ARE ATTENDED WITH THE GREATEST PAIN. NAMES OF PERSONS WHO HAVE DISCOVERED FAMOUS PLANTS.

In former times there was a sort of ambition, as it were, of adopting plants, by bestowing upon them one's name, a thing that has been done before now by kings even, as we shall have occasion to show: so desirable a thing did it appear to have made the discovery of some plant, and thus far to have contributed to the benefit of mankind. At the present day, however, it is far from impossible that there may be some who will look upon these researches of ours as frivolous even, so distasteful to a life of ease and luxury are the very things which so greatly conduce to our welfare.

Still, however, it will be only right to mention in the first place those plants the discoverers of which are known, their various properties being classified according to the several maladies for the treatment of which they are respectively employed: in taking a review of which one cannot do otherwise than bemoan the unhappy lot of mankind, subject as it is, in addition to chances and changes, and those new afflictions which every hour is bringing with it, to thousands of diseases which menace the existence of each mortal being. It would seem almost an act of folly to attempt to determine which of these diseases is attended with the most excruciating pain, seeing that every one is of opinion that the malady with which for the moment he himself is afflicted, is the most excruciating and insupportable. The general experience, however, of the present age has come to the conclusion, that the most agonizing torments are those attendant upon strangury, resulting from calculi in the bladder; next to them, those arising from maladies of the stomach; and in the third place, those caused by pains and affections of the head; for it is more generally in these cases, we find, and not in others, that patients are tempted to commit suicide.

For my own part, I am surprised that the Greek authors have gone so far as to give a description of noxious plants even; in using which term, I wish it to be understood that I do not mean the poisonous plants merely; for such is our tenure of life that death is often a port of refuge to even the best of men. We meet too, with one case of a somewhat similar nature, where M. Varro speaks of Servius Clodius, a member of the Equestrian order, being so dreadfully tormented with gout, that he had his legs rubbed all over with poisons, the result of which was, that from that time forward all sensation, equally with all pain, was deadened in those parts of his body. But what excuse, I say, can there be for making the world acquainted with plants, the only result of the use of which is to derange the intellect, to produce abortion, and to cause numerous other effects equally pernicious? So far as I am concerned, I shall describe neither abortives nor philtres, bearing in mind, as I do, that Lucullus, that most celebrated general, died of the effects of a philtre. Nor shall I speak

of other ill-omened devices of magic, unless it be to give warning against them, or to expose them, for I most emphatically condemn all faith and belief in them. It will suffice for me, and I shall have abundantly done my duty, if I point out those plants which were made for the benefit of mankind, and the properties of which have been discovered in the lapse of time.

Detailed table of contents

CHAP. 8. (4.)

MOLY: THREE REMEDIES.

According to Homer, the most celebrated of all plants is that, which, according to him, is known as moly among the gods. The discovery of it he attributes to Mercury, who was also the first to point out its uses as neutralizing the most potent spells of sorcery. At the present day, it is said, it grows in the vicinity of Lake Pheneus, and in Cyllene, a district of Arcadia. It answers the description given of it by Homer, having a round black root, about as large as an onion, and a leaf like that of the squill: there is no difficulty experienced in taking it up. The Greek writers have delineated it as having a yellow flower, while Homer, on the other hand, has spoken of it as white. I once met with a physician, a person extremely well acquainted with plants, who assured me that it is found growing in Italy as well, and that he would send me in a few days a specimen which had been dug up in Campania, with the greatest difficulty, from a rocky soil. The root of it was thirty Feet in length, and even then it was not entire, having been broken in the getting up.

Detailed table of contents

CHAP. 9.

THE DODECATHEOS: ONE REMEDY.

The plant next in esteem to moly, is that called dodecatheos, it being looked upon as under the especial tutelage of all the superior gods. Taken in water, it is a cure, they say, for maladies of every kind. The leaves of it, seven in number, and very similar to those of the lettuce, spring from a yellow root.

[Detailed table of contents](#)

CHAP. 10.

THE PÆONIA, PENTOROBUS, OR GLYCYSIDE: ONE REMEDY.

The plant known as “pæonia” is the most ancient of them all. It still retains the name of him who was the first to discover it, being known also as the “pentorobus” by some, and the “glycyside” by others; indeed, this is one of the great difficulties attendant on forming an accurate knowledge of plants, that the same object has different names in different districts. It grows in umbrageous mountain localities, and puts forth a stem amid the leaves, some four fingers in height, at the summit of which are four or five heads resembling Greek nuts in appearance; enclosed in which, there is a considerable quantity of seed of a red or black colour. This plant is a preservative against the illusions practised by the Fauni in sleep. It is generally recommended to take it up at night; for if the wood-pecker of Mars should perceive a person doing so, it will immediately attack his eyes in defence of the plant.

Detailed table of contents

CHAP. 11.

THE PANACES ASCLEPION: TWO REMEDIES.

The panaces, by its very name, gives assurance of a remedy for all diseases: there are numerous kinds of it, and the discovery of its properties has been attributed to the gods. One of these kinds is known by the additional name of “asclepion,” in commemoration of the circumstance that Æsculapius gave the name of Panacia to his daughter. The juice of it, as we have had occasion to remark already, coagulates like that of fennel-giant; the root is covered with a thick rind of a salt flavour.

After this plant has been taken up, it is a point religiously observed to fill the hole with various kinds of grain, a sort of expiation, as it were, to the earth. We have already stated, when speaking of the exotic productions, where and in what manner this juice is prepared, and what kind is the most esteemed. That which is imported from Macedonia is known as “bucolicon,” from the fact that the neatherds there are in the habit of collecting it as it spontaneously exudes: it evaporates, however, with the greatest rapidity. As to the other kinds, that more particularly is held in disesteem which is black and soft, such being a proof, in fact, that it has been adulterated with wax.

Detailed table of contents

CHAP. 12.

THE PANACES HERACLEON: THREE REMEDIES.

A second kind of panaces is known by the name of “heracleon,” from the fact that it was first discovered by Hercules. Some persons, however, call it “Heracleotic origanum,” or wild origanum, from its strong resemblance to the origanum of which we have already spoken: the root of it is good for nothing.

Detailed table of contents

CHAP. 13.

THE PANACES CHIRONION: FOUR REMEDIES.

A third kind of panaces is surnamed “chironion,” from him who first discovered it. The leaf is similar to that of lapathum, except that it is larger and more hairy; the flower is of a golden colour, and the root diminutive. It grows in rich, unctuous soils. The flower of this plant is extremely efficacious; hence it is that it is more generally used than the kinds previously mentioned.

Detailed table of contents

CHAP. 14.

THE PANACES CENTAURION OR PHARNACION: THREE REMEDIES.

A fourth kind of panaces, discovered also by Chiron, is known by the additional name of “centaurion:” it is also called “pharnacion,” from King Pharnaces, it being a matter in dispute whether it was really discovered by Chiron or by that prince. It is grown from seed, and the leaves of it are longer than those of the other kinds, and serrated at the edge. The root, which is odoriferous, is dried in the shade, and is used for imparting an aroma to wine. Some writers distinguish two varieties of this plant-the one with a smooth leaf, the other of a more delicate form.

Detailed table of contents

CHAP. 15.

THE HERACLEON SIDERION: FOUR REMEDIES.

The heracleon siderion is also another discovery of Hercules. The stem is thin, about four fingers in length, the flower red, and the leaves like those of coriander. It is found growing in the vicinity of lakes and rivers, and is extremely efficacious for the cure of all wounds made by iron.

Detailed table of contents

CHAP. 16.

THE AMPELOS CHIRONIA: ONE REMEDY.

The ampelos Chironia also, which we have already mentioned when speaking of the vines, is a discovery due to Chiron. We have spoken too, on a previous occasion, of a plant, the discovery of which is attributed to Minerva.

Detailed table of contents

CHAP. 17.

HYOSCYAMOS, KNOWN ALSO AS THE APOLLINARIS OR ALTERCUM; FIVE VARIETIES OF IT: THREE REMEDIES.

To Hercules also is attributed the discovery of the plant known as the “apollinaris,” and, among the Arabians, as the “altercum” or “altercangenum:” by the Greeks it is called “hyoscyamos.” There are several varieties of it; one of them, with a black seed, flowers bordering on purple, and a prickly stem, growing in Galatia. The common kind again, is whiter, more shrublike, and taller than the poppy. The seed of a third variety is similar to that of irio in appearance; but they have, all of them, the effect of producing vertigo and insanity. A fourth kind again is soft, lanuginous, and more unctuous than the others; the seed of it is white, and it grows in maritime localities. It is this kind that medical men employ, as also that with a red seed. Sometimes, however, the white seed turns of a reddish colour, if not sufficiently ripe when gathered; in which case it is rejected as unfit for use: indeed, none of these plants are gathered until they are perfectly dry. Hyoscyamos, like wine, has the property of flying to the head, and consequently of acting injuriously upon the mental faculties.

The seed is either used in its natural state, or else the juice of it is extracted: the juice also of the stem and leaves is sometimes extracted, separately from the seed. The root is sometimes made use of; but the employment of this plant in any way for medical purposes is, in my opinion, highly dangerous. For it is a fact well ascertained, that the leaves even will exercise a deleterious effect upon the mind, if more than four are taken at a the; though the ancients were of opinion that the leaves act as a febrifuge, taken in wine. From the seed, as already stated, an oil is extracted, which, injected into the ears, deranges the intellect. It is a singular thing, but we find remedies mentioned for those who have taken this juice, as though for a poison, while at the same time we find it prescribed as a potion among the various remedies. In this way it is that experiments are multiplied without end, even to forcing the very poisons themselves to act as antidotes.

Detailed table of contents

CHAP. 18. (5.)

LINOZOSTIS, PARTHENION, HERMUPOA, OR MER- CURIALIS; TWO VARIETIES OF IT: TWENTY-TWO REMEDIES.

Linozostis or parthenion is a discovery attributed to Mer- cury: hence it is that among the Greeks it is known as “hermupoa” by many, while among us it is universally known as “mercurialis.” There are two varieties of this plant, the male and the female, the last possessing more decided properties than the other, and having a stem a cubit in height, and sometimes branchy at the summit, with leaves somewhat narrower than those of ocimum. The joints of the stem lie close together, and the axils are numerous: the seed hangs downwards, having the joints for its basis. In the female plant the seed is very abundant, but in the male it is less so, lies closer to the joints, and is short and wreathed. In the female plant the seed hangs more loosely, and is of a white colour. The leaves of the male plant are swarthy, while those of the female are whiter: the root, which is made no use of, is very diminutive.

Both of these plants grow in cultivated champaign localities. A marvellous property is mentioned as belonging to them: the male plant, they say, ensures the conception of male children, the female plant of females; a result which is ensured by drinking the juice in raisin wine, the moment after conception, or by eating the leaves, boiled with oil and salt, or raw with vinegar. Some persons, again, boil the plant in a new earthen vessel with heliotropium and two or three ears of corn, till it is thoroughly done; and say that the decoction should be taken in drink by the female, and the plant eaten for three days successively, the regimen being commenced the second day of menstruation. This done, on the fourth day she must take a bath, immediately after which the sexual congress must take place.

Hippocrates has lavished marvellous encomiums upon these plants for the maladies of females, while at the present day no physician recognizes their utility for such purpose. It was his practice to employ them for affections of the uterus, in the form of a pessary, in combination with honey, rose-oil, oil of iris, or oil of lilies. He employed them also as an emmenagogue, and for the purpose of bringing away the after-birth; effects which are equally produced, according to him, by taking them in drink, or using them in the form of a fomentation. It was his practice also, to inject the juice of these plants in cases of fetid odours of the ears, and then to wash the ear with old wine. The leaves also were used by him as a cataplasm for the abdomen, defluxions of the eyes, strangury, and affections of the bladder; a decoction too, of the plants is prescribed by him, with frankincense and myrrh.

For the purpose of relaxing the bowels, or in cases of fever, a handful of this plant is boiled down to one half, in two sextarii of water, the decoction being taken with salt and honey: if a pig’s foot or a cock is boiled with it, it will be all the more beneficial. Some persons have been of opinion, that as a

purgative the two kinds of mercurialis ought to be used together, or else that a decoction should be made of the plant in combination with mallows. These plants act as a detergent upon the chest, and carry off the bilious secretions, but they are apt to be injurious to the stomach. We shall have to speak further of their properties on the appropriate occasions.

Detailed table of contents

CHAP. 19.

THE ACHILLEOS, SIDERITIS, PANACES HERACLEON, MILLEFOLIUM, OR SCOPÆ
REGLÆ; SIX VARIETIES OF IT: THREE REMEDIES.

Achilles too, the pupil of Chiron, discovered a plant which heals wounds, and which, as being his discovery, is known as the “achilleos.” It was by the aid of this plant, they say, that he cured Telephus. Other authorities, however, assert that He was the first to discover that verdigris is an extremely useful ingredient in plasters; and hence it is that he is sometimes represented in pictures as scraping with his sword the rust from off a spear into the wound of Telephus. Some again, are of opinion that he made use of both remedies.

By some persons this plant is called “panaces heracleon,” by others, “sideritis,” and by the people of our country, “millefolium:” I the stalk of it, they say, is a cubit in length, branchy, and covered from the bottom with leaves somewhat smaller than those of fennel. Other authorities, however, while admitting that this last plant is good for wounds, affirm that the genuine achilleos has a bluish stem a foot in length, destitute of branches, and elegantly clothed all over with isolated leaves of a round form. Others again, maintain that it has a squared stem, that the heads of it are small and like those of horehound, and that the leaves are similar to those of the quercus — they say too, that this last has the property of uniting the sinews when cut asunder. Another statement is, that the sideritis is a plant that grows on garden walls, and that it emits, when bruised, a fetid smell; that there is also another plant, very similar to it, but with a whiter and more unctuous leaf, a more delicate stem, and mostly found growing in vineyards.

They speak also of another sideritis, with a stem two cubits in length, and diminutive branches of a triangular shape: the leaf, they say, resembles that of fern, and has a long footstalk, the seed being similar to that of beet. All these plants, it is said, are remarkably good for the treatment of wounds. The one with the largest leaf is known among us by the name of “scopæ regiæ,” and is used for the cure of quinzey in swine.

Detailed table of contents

CHAP. 20.

THE TEUCRION, HEMIONION, OR SPLENION: TWO REMEDIES.

At the same period also, Teucer discovered the teucrion, a plant known to some as the “hemionion.” It throws out thin rush-like stems, with diminutive leaves, and grows in rugged, uncultivated spots: the taste of it is rough, and it never blossoms or produces seed. It is used for the cure of affections of the spleen, and it is generally understood that its properties were discovered in the following manner: — The entrails of a victim having been placed upon this plant, it attached itself to the milt, and entirely consumed it; a property to which it is indebted for the name of “splenion,” given to it by some. It is said too, that swine which have fed upon the root of this plant are found to have no milt.

Some authors give this name also to a ligneous plant, with branches like those of hyssop, and a leaf resembling that of the bean; they say too, that it should be gathered while in blossom, from which we may conclude that they entertain no doubt that it does blossom. That which grows on the mountains of Cilicia and Pisidia is more particularly praised by them.

Detailed table of contents

CHAP. 21.

MELAMPODIUM, HELLEBORE, OR VERATRUM: THREE VARIETES OF IT. THE WAY IN WHICH IT IS GATHERED, AND HOW THE QUALITY OF IT IS TESTED.

The repute of Melampus, as being highly skilled in the arts of divination, is universally known. This personage has given a name to one species of hellebore, known as the “Melampodion.” Some persons, however, attribute the discovery of this plant to a shepherd of that name, who remarked that his she-goats were violently purged after browsing upon it, and afterwards cured the daughters of Proetus of madness, by, giving them the milk of these goats. It will be the best plan, therefore, to take this opportunity of treating of the several varieties of hellebore. The two principal kinds are the white and the black; though, according to most authorities, this difference exists in the root only. There are some authors, however, who assure us that the leaves of the black hellebore are similar to those of the plane-tree, only darker, more diminutive, and more jagged at the edges: and who say, that the white hellebore has leaves like those of beet when first shooting, though at the same time of a more swarthy colour, with reddish veins on the under side. The stem, in both kinds, is ferulaceous, a palm in height, and covered with coats like those of the bulbs, the root, too, being fibrous like that of the onion.

The black hellebore kills horses, oxen, and swine; hence it is that those animals avoid it, while they eat the white kind. The proper time, they say, for gathering this last, is harvest. It grows upon Mount Cæta in great abundance; and the best of all is that found upon one spot on that mountain, in the vicinity of Pyra. The black hellebore is found growing every- where, but the best is that of Mount Helicon; which is also equally celebrated for the qualities of its other plants. The white hellebore of Mount Cæta is the most highly esteemed, that of Pontus occupying the second place, and the produce of Elea the third; which last, it is generally said, grows in the vineyards there. The fourth rank is held by the white hellebore of Mount Parnassus, though it is often adulterated with that of the neighbouring districts of Ætolia.

Of these kinds it is the black hellebore that is known as the “melampodium:” it is used in fumigations, and for the purpose of purifying houses; cattle, too, are sprinkled with it, a certain form of prayer being repeated. This last plant, too, is gathered with more numerous ceremonies than the other: a circle is first traced around it with a sword, after which, the person about to cut it turns towards the East, and offers up a prayer, entreating permission of the gods to do so. At the same time he observes whether an eagle is in sight — for mostly while the plant is being gathered that bird is near at hand — and if one should chance to fly close at hand, it is looked upon as a presage that he will die within the year. The white hellebore, too, is gathered not without difficulty, as it is very oppressive to the Head; more particularly if the precaution has not been used of eating garlic first, and of

drinking wine every now and then, care being taken to dig up the plant as speedily as possible.

Some persons call the black hellebore “ectomon,” and others “polyrrhizon:” it purges by stool, while the white hellebore acts as an emetic, and so carries off what might otherwise have given rise to disease. In former days hellebore was regarded with horror, but more recently the use of it has become so familiar, that numbers of studious men are in the habit of taking it for the purpose of sharpening the intellectual powers required by their literary investigations. Carneades, for instance, made use of hellebore when about to answer the treatises of Zeno; Drusus too, among us, the most famous of all the tribunes of the people, and whom in particular the public, rising from their seats, greeted with loud applause—to whom also the patricians imputed the Marsic war—is well known to have been cured of epilepsy in the island of Anti-cyra; a place at which it is taken with more safety than elsewhere, from the fact of sesamoides being combined with it, as already stated. In Italy the name given to it is “veratrum.”

These kinds of hellebore, reduced to powder and taken alone, or else in combination with radícula, a plant used, as already mentioned, for washing wool, act as a sternutatory, and are both of them productive of narcotic effects. The thinnest and shortest roots are selected, and among them the lower parts in particular, which have all the appearance of having been cut short; for, is to the upper part, which is the thickest, and bears a resemblance to an onion, it is given to dogs only, as a purgative. The ancients used to select those roots the rind of which was the most fleshy, from an idea that the pith extracted therefrom was of a more refined nature. This substance they covered with wet sponges, and, when it began to swell, used to split it longitudinally with a needle; which done, the filaments were dried in the shade, for future use. At the present day, however, the fibres of the root with the thickest rind are selected, and given to the patient just as they are. The best hellebore is that which has an acrid, burning taste, and when broken, emits a sort of dust. It retains its efficacy, they say, so long as thirty years.

Detailed table of contents

CHAP. 22.

TWENTY-FOUR REMEDIES DERIVED FROM BLACK HELLE-BORE. HOW IT SHOULD BE TAKEN.

Black hellebore is administered for the cure of paralysis, insanity, dropsy — provided there is no fever — chronic gout, and diseases of the joints: it has the effect too, of carrying off the bilious secretions and morbid humours by stool. It is given also in water as a gentle aperient, the proportion being one drachma at the very utmost, and four oboli for a moderate dose. Some authorities have recommended mixing scammony with it, but salt is looked upon as more safe. If given in any considerable quantity in combination with a sweet substance, it is highly dangerous: used in the form of a fomentation, it disperses films upon the eyes; and hence it is that some medical men have pounded it and used it for an eye-salve. It ripens and acts detergently upon scrofulous sores, suppurations, and indurated tumours, as also upon fistulas, but in this latter case it must be removed at the end of a couple of days. In combination with copper filings and sandarach, it removes warts; and it is applied to the abdominal regions, with barley-meal and wine, in cases of dropsy.

This plant is employed for the cure of pituitous defluxions in cattle and beasts of burden, a slip of it being passed through the ear, and removed at the same hour on the following day. With frankincense also, wax, and pitch, or else pisselæon, it is used for the cure of itch in quadrupeds.

Detailed table of contents

CHAP. 23.

TWENTY-THREE REMEDIES DERIVED FROM WHITE HELLEBORE.

The best white hellebore is that which acts most speedily as a sternutatory; but it would seem to be a much more formidable plant than the black kind; more particularly if we read in the ancient authors the precautions used by those about to take it, against cold shiverings, suffocation, unnatural drowsiness, continuous hiccup or sneezing, derangements of the stomach, and vomitings, either retarded or prolonged, too sparing or in excess. Indeed, it was generally the practice to administer other substances to promote vomiting, and to carry off the hellebore by the aid of purgatives or clysters, while bleeding even was frequently had recourse to. In addition to all this, however successful the results may prove, the symptoms by which it is attended are really most alarming, by reason of the various colours which the matter vomited presents: besides which, after the vomiting has subsided, the physician has to pay the greatest attention to the nature of the alvine evacuations, the due and proper use of the bath, and the general regimen adopted by the patient; all of them inconveniences in themselves, and preceded by the terrors naturally inspired by the character of the drug; for one story is, that it has the property of consuming flesh, if boiled with it.

The great error, however, on the part of the ancients was, that in consequence of these fears, they used to give it too sparingly, the fact being, that the larger the dose, the more speedily it passes through the body. Themison used to give no more than two drachmæ, but at a later period as much as four drachmæ was administered; in conformity with the celebrated eulogium passed upon it by Herophilus, who was in the habit of comparing hellebore to a valiant general, and saying, that after it has set in motion all within, it is the first to sally forth and show the way. In addition to these particulars, there has been a singular discovery made: the hellebore which, as we have already stated, has been cut with a small pair of scissors, is passed through a sieve, upon which the pith makes its way through, while the outer coat remains behind. The latter acts as a purgative, while the former is used for the purpose of arresting vomiting when that evacuation is in excess.

Detailed table of contents

CHAP. 24.

EIGHTY-EIGHT OBSERVATIONS UPON THE TWO KINDS OF HELLEBORE.

In order to secure a beneficial result, due precautions must be taken not to administer hellebore in cloudy weather; for if given at such a time, it is sure to be productive of excruciating agonies. Indeed there is no doubt that summer is a better time for giving it than winter: the body too, by an abstinence from wine, must be prepared for it seven days previously, emetics being taken on the fourth and third days before, and the patient going without his evening meal the previous day. White hellebore, too, is administered in a sweet medium, though lentils or pottage are found to be the best for the purpose. There has been a plan also, lately discovered, of splitting a radish, and inserting the hellebore in it, after which the sections are pressed together; the object being that the strength of the hellebore may be incorporated with the radish, and modified thereby.

At the end of about four hours it generally begins to be brought up again; and within seven it has operated to the full extent. Administered in this manner, it is good for epilepsy, as already stated, vertigo, melancholy, insanity, delirium, white elephantiasis, leprosy, tetanus, palsy, gout, dropsy, incipient tympanitis, stomachic affections, cynic spasms, sciatica, quartan fevers which defy all other treatment, chronic coughs, flatulency, and recurrent grippings in the bowels.

Detailed table of contents

CHAP. 25.

TO WHAT PERSONS HELLEBORE SHOULD NEVER BE ADMINISTERED.

It is universally recommended not to give hellebore to aged people or children, to persons of a soft and effeminate habit of body or mind, or of a delicate or tender constitution. It is given less frequently too to females than to males; and persons of a timorous disposition are recommended not to take it: the same also, in cases where the viscera are ulcerated or tumefied, and more particularly when the patient is afflicted with spitting of blood, or with maladies of the side or fauces. Hellebore is applied, too, externally, with salted axle-grease, to morbid eruptions of the body and suppurations of long standing: mixed with polenta, it destroys rats and mice. The people of Gaul, when hunting, tip their arrows with hellebore, taking care to cut away the parts about the wound in the animal so slain: the flesh, they say, is all the more tender for it. Flies are destroyed with white hellebore, bruised and sprinkled about a place with milk: phthiriasis is also cured by the use of this mixture.

CHAP. 26. (6.)

THE MITHRIDATIA.

Crateuas ascribes the discovery of one plant to Mithridates himself, the name of which is “mithridatia.” Near the root it has two leaves resembling those of the acanthus, between which it puts forth a stem supporting a flower at the extremity, like a rose.

Detailed table of contents

CHAP. 27.

THE SCORDOTIS OR SCORDION: FOUR REMEDIES.

Lennæus attributes to Mithridates the discovery of another plant, the scordotis or scordion, which has been described, he tells us, by the hand even of that prince. This plant, he says, is a cubit in height, and has a square stem, branchy, covered with downy leaves, and resembling the quercus in appearance: it is found growing in Pontus, in rich, humid soils, and has a bitter taste.

There is another variety also of this plant, with a larger leaf, and resembling wild mint in appearance. They are both of them used for numerous purposes, both individually and in combination with other ingredients, as antidotes.

Detailed table of contents

CHAP. 28.

THE POLEMONIA, PHILETÆRIA, OR CHILIODYNAMUS: SIX REMEDIES.

The polemonia is known as the “philetæria” by some, in consequence of the contest which has arisen between certain kings for the honour of its discovery. The people of Cappadocia also give it the name of “chiliodynamus.” The root of it is substantial, and it has slender branches, with umbels hanging from the extremities, and a black seed. In other respects, it bears a resemblance to rue, and is found growing in mountainous localities.

Detailed table of contents

CHAP. 29.

THE EUPATORIA: ONE REMEDY.

The eupatoria also is a plant under royal patronage. The stem of it is ligneous, hairy, and swarthy, and a cubit or more in length. The leaves, arranged at regular intervals, resemble those of cinquefoil or hemp; they have five indentations at the edge, and are swarthy like the stem, and downy. The root is never used. The seed, taken in wine, is a sovereign remedy for dysentery.

[Detailed table of contents](#)

CHAP. 30.

CENTAURION OR CHIRONION: TWENTY REMEDIES.

Centaury, it is said, effected a cure for Chiron, on the occasion when, while handling the arms of Hercules, his guest, he let one of the arrows fall upon his foot: hence it is that by some it is called “chironion.” The leaves of it are large and oblong, serrated at the edge, and growing in thick tufts from the root upwards. The stems, some three cubits in height and jointed, bear heads resembling those of the poppy. The root is large and spreading, of a reddish colour, tender and brittle, a couple of cubits in length, and full of a bitter juice, somewhat inclining to sweet.

This plant grows in rich soils upon declivities; the best in quality being that of Arcadia, Elis, Messenia, Mount Pholoë, and Mount Lycæus: it grows also upon the Alps, and in numerous other localities, and in Lycia they prepare a lycium from it. So remarkable are its properties for closing wounds, that pieces of meat even, it is said, are soldered together, when boiled with it. The root is the only part in use, being administered in doses of two drachmæ in the several cases hereafter mentioned. If, however, the patient is suffering from fever, it should be bruised and taken in water, wine being used in other cases. A decoction of the root is equally useful for all the same purposes.

Detailed table of contents

CHAP. 31.

THE CENTAURION LEPTON, OR LIBATION, KNOWN ALSO AS FELL TERRÆ:
TWENTY-TWO REMEDIES.

There is another centaury also, with diminutive leaves, known by the additional name of “lepton.” By some persons it is called “libadion,” from the circumstance that it grows upon the borders of fountains. It is similar to origanum in appearance, except that the leaves are narrower and longer. The stem is angular, branchy, and a palm in height; the flower is like that of the lychnis, and the root is thin, and never used. It is in the juice that its medicinal properties are centred: it being gathered in the autumn, and the juice extracted from the leaves. Some persons cut up the stalks, and steep them for some eighteen days in water, and then extract the juice.

In Italy this kind of centaury is known as “gall” of the earth,” from its extreme bitterness. The Gauls give it the name of “exacum;” from the circumstance that, taken in drink, it purges off all noxious substances by alvine evacuation.

Detailed table of contents

CHAP. 32.

THE CENTAURIS TRIORCHIS: TWO REMEDIES.

There is a third kind of centaury also, known as the “centauris triorchis.” It is but rarely that a person cuts it without wounding himself. The juice emitted is just the colour of blood. Theophrastus relates that this plant is under the protection of the triorchis, a kind of hawk, which attacks those who gather it; a circumstance to which it owes its name. Ignorant persons are in the habit of confounding all these characteristics, and attributing them to the centaury first named.

[Detailed table of contents](#)

CHAP. 33. (7).

CLYMENUS : TWO REMEDIES.

Clymenus is a plant so called, after a certain king. It has leaves like those of ivy, numerous branches, and a hollow, jointed stem. The smell of it is powerful, and the seed like that of ivy: it grows in wild and mountainous localities. We shall have to state hereafter, of what maladies it is curative, taken in drink, but it is as well to take the present opportunity of remarking that, while effecting a cure, in the male sex it neutralizes the generative powers.

The Greeks speak of this plant as being similar to the plantago in appearance, with a square stem, and a seed in capsules, interlaced like the arms of the polypus. The juice of this plant, too, is used, being possessed of refreshing properties in a very high degree.

Detailed table of contents

CHAP. 34.

GENTIAN: THIRTEEN REMEDIES.

Gentian was first discovered by Gentius, king of Illyria. It is a plant to be found everywhere, but that of Illyria is the finest. It has a leaf like that of the ash, but equal in size to a lettuce-leaf: the stem is tender, about the thickness of the thumb, hollow and empty, and covered with leaves at regular intervals. This stem is sometimes three cubits in length, and the root is flexible, swarthy, and inodorous. It is found in the greatest abundance in humid localities at the foot of the Alps. The root and juice are the parts of it that are used: the root is possessed of certain warming properties, but it should never be taken by women in a state of pregnancy.

Detailed table of contents

CHAP. 35.

THE LYSIMACHIA: EIGHT REMEDIES,

King Lysimachus first discovered the plant which from him has received the name of lysimachia, and the merits of which have been so highly extolled by Erasistratus. This plant has green leaves resembling those of the willow, and a purple blossom: it has all the appearance of a shrub, the branches are erect, and it has a pungent smell. It is found growing in watery soils. The properties of it are so extremely powerful, that if placed upon the yoke when beasts of burden are restive, it will be sure to overcome all stubbornness on their part.

[Detailed table of contents](#)

CHAP. 36.

ARTEMISIA, PARTHENIS, BOTRYS, OR AMBROSIA: FIVE REMEDIES.

Women too have even affected an ambition to give their name to plants: thus, for instance, Artemisia, the wife of King Mausolus, adopted the plant, which before was known by the name of “parthenis.” There are some persons, however, who are of opinion that it received this surname from the goddess Artemis Ilithyia, from the fact of its being used for the cure of female complaints more particularly. It is a plant with numerous branches, like those of wormwood, but the leaves of it are larger and substantial.

There are two varieties of it; one has broader leaves than the other, which last is of a slender form, with a more diminutive leaf, and grows nowhere but in maritime districts.

Some persons again, give this name to a plant which grows more inland, with a single stem, extremely diminutive leaves, and numerous blossoms which open at the ripening of the grape, and the odour of which is far from unpleasant. In addition to this name, this last plant is known as “botrys” to some persons, and “ambrosia” to others: it grows in Cappadocia.

Detailed table of contents

CHAP. 37.

NYMPHÆA, HERACLEON, RHOPALON, OR MADON; TWO VARIETIES OF IT:
FOUR REMEDIES.

The plant called “nymphæa,” owes its name, they say, to a Nymph who died of jealousy conceived on account of Hercules, for which reason it is also known as “heracleon” by some. By other persons, again, it is called “rhopalon,” from the resemblance of its root to a club. * * * * and hence it is that those who take it in drink become impotent for some twelve days, and incapacitated for procreation. That of the first quality is found in Orchomenia and at Marathon: the people of Bœotia call it “madon,” and use the seed for food. It grows in spots covered with water; the leaves of it are large, and float upon the surface, while others are to be seen springing from the roots below. The flower is very similar to a lily in appearance, and after the plant has shed its blossom, the place of the flower is occupied by a head like that of the poppy. The stem is slender, and the plant is usually cut in autumn. The root, of a swarthy hue, is dried in the sun; garlic manifests a peculiar antipathy to it.

There is another nymphæa also, which grows in the river Peneus, in Thessaly: the root of it is white, and the head yellow, about the size of a rose.

Detailed table of contents

CHAP. 38.

TWO VARIETIES OF EUPHORBIA: FOUR REMEDIES. THE CHAMELÆA.

In the time, too, of our fathers, King Juba discovered a plant, to which he gave the name of “euphorbia,” in honour of his physician, Euphorbus, the brother of the same Musa, whom We have mentioned as having saved the life of the late Emperor Augustus. It was these brothers who introduced the practice of douching the body with large quantities of cold water, immediately after the bath, for the purpose of bracing the system: whereas in former times, as we find stated in the works of Homer even, it was the practice to wash the body with warm water only. With reference to euphorbia, there is a treatise still in existence, written upon it by King Juba, in which he highly extols its merits: he discovered it growing upon Mount Atlas, and describes it as resembling a thyrus in appearance, and bearing leaves like those of the acanthus.

The properties of this plant are so remarkably powerful, that the persons engaged in collecting the juices of it are obliged to stand at a considerable distance. The incisions are made with a long pole shod with iron, the juice flowing into receivers of kid-leather placed beneath. The juice has all the appearance of milk, as it exudes, but when it has coagulated and dried, it assumes the form and consistency of frankincense. The persons engaged in collecting it, find their sight improved thereby. This juice is an excellent remedy for the stings of serpents: in whatever part of the body the wound may have been inflicted, the practice is to make an incision in the crown of the head, and there introduce the medicament. The Gætuli who collect it, are in the habit of adulterating it with warm milk; a fraud, however, easily to be detected by the agency of fire, that which is not genuine emitting a most disgusting smell.

Much inferior to this is the juice extracted, in Gaul, from the chamelæa, a plant which bears the grain of Cnidos. When broken asunder, it resembles hammoniacum in appearance; and however slightly tasted, it leaves a burning sensation in the mouth, which lasts a considerable time, and increases every now and then, until, in fact, it has quite parched the fauces.

[Detailed table of contents](#)

CHAP. 39. (8.)

TWO VARIETIES OF THE PLANTAGO: FORTY-SIX REMEDIES.

The physician Themiso, too, has conferred some celebrity upon the plantago, otherwise a very common plant; indeed he has written a treatise upon it, as though he had been the first to discover it. There are two varieties; one, more diminutive than the other, has a narrower and more swarthy leaf, strongly resembling a sheep's tongue in appearance: the stem of it is angular and bends downwards, and it is generally found growing in meadow lands. The larger kind has leaves enclosed with ribs at the sides, to all appearance, from the fact of which being seven in number, the plant has been called "heptapleuron" by some. The stem of it is a cubit in height, and strongly resembles that of the turnip. That which is grown in a moist soil is considered much the most efficacious: it is possessed of marvellous virtues as a desiccative and as an astringent, and has all the effect of a cautery. There is nothing that so effectually arrests the fluxes known by the Greeks as "rheumatismi."

Detailed table of contents

CHAP. 40.

BUGLOSSOS: THREE REMEDIES.

To an account of the plantago may be annexed that of the buglossos, the leaf of which resembles an ox tongue. The main peculiarity of this plant is, that if put into wine, it promotes mirth and hilarity, whence it has obtained the additional name of “euphrosynum.”

Detailed table of contents

CHAP. 41.

CYNOGLOSSOS: THREE REMEDIES.

To this plant we may also annex an account of the cynoglossos, the leaf of which resembles a dog's tongue, and which produces so pleasing an effect in ornamental gardening. The root, it is said, of the kind which bears three stems surmounted with seed, is very useful, taken in water, for tertian, and of that with four stems, for quartan, fevers.

There is another plant very similar to it, which bears diminutive burrs resembling those of the lappa: the root of it, taken in water, is curative of wounds inflicted by frogs or serpents.

[Detailed table of contents](#)

CHAP. 42.

THE BUPHTALMOS OR CACHLA: ONE REMEDY.

There is the buphthalmos also, so called from its resemblance to an ox's eye, and with a leaf like that of fennel. It grows in the vicinity of towns, and is a branchy plant, with numerous stems, which are boiled and eaten. Some persons give it the name of "cachla." In combination with wax, it disperses scirrhi.

Detailed table of contents

CHAP. 43.

PLANTS WHICH HAVE BEEN DISCOVERED BY CERTAIN NATIONS. THE
SCYTHICE: ONE REMEDY.

Entire nations, too, have been the discoverers of certain plants. The Scythæ were the first to discover the plant known as “scythice,” which grows in the vicinity of the Palus Mæotis. Among its other properties, this plant is remarkably sweet, and extremely useful for the affection known as “asthma.” It is also possessed of another great recommendation — so long as a person keeps it in his mouth, he will never experience hunger or thirst.

Detailed table of contents

CHAP. 44.

THE HIPPACE: THREE REMEDIES.

The hippace, another plant that grows in Scythia, is possessed of similar properties: it owes its name to the circumstance that it produces the like effect upon horses. By the aid of these two plants, the Scythæ, they say, are enabled to endure hunger and thirst, so long as twelve days even.

Detailed table of contents

CHAP. 45.

THE ISCHÆMON: TWO REMEDIES.

The Thracians were the first to discover the ischæmon, which, it is said, has the property of stanching the flow of blood, not only when a vein has been opened, but when it has been cut asunder even. This is a creeping plant; it is like millet in appearance, and the leaves of it are rough and lanuginous. It is used as a plug for the nostrils. The kind that grows in Italy, attached to the body as an amulet, has the property of arresting hæmorrhage.

[Detailed table of contents](#)

CHAP. 46.

THE CESTROS, PSYCHOTROPEION, VETTONICA, OR SERRA- TULA: FORTY- EIGHT REMEDIES.

The Vettones, a people of Spain, were the original discoverers of the plant known as the “vettonica” in Gaul, the “serratula” in Italy, and the “cestros” or “psychotrophon” in Greece. This is a plant more highly esteemed than any other: it puts forth an angular stem two cubits in height, and throws out leaves from the root, with serrated edges, and closely resembling those of lapathum. The seed of it is purple: the leaves are dried and powdered, and used for numerous purposes. There is a wine also prepared from it, and a vinegar, remarkably beneficial to the stomach and the eyesight. Indeed, this plant enjoys so extraordinary a reputation, that it is a common belief even that the house which contains it is insured against misfortunes of every kind.

Detailed table of contents

CHAP. 47.

THE CANTABRICA: TWO REMEDIES.

In Spain, too, is found the cantabrica, which was first discovered by the nation of the Cantabri in the time of the late Emperor Augustus. It grows everywhere in those parts, having a stem like that of the bulrush, a foot in height, and bearing small oblong flowers, like a calathus in shape, and enclosing an extremely diminutive seed. Nor indeed, in other respects, have the people of Spain been wanting in their researches into the nature of plants; for at the present day even it is the custom in that country, at their more jovial entertainments, to use a drink called the hundred-plant drink, combined with a proportion of honied wine; it being their belief, that the wine is rendered more whole- some and agreeable by the admixture of these plants. It still remains unknown to us, what these different plants are, or in what number exactly they are used: as to this last question, however, we may form some conclusion from the name that is given to the beverage.

Detailed table of contents

CHAP. 48.

CONSILIGO: ONE REMEDY.

Our own age, too, can remember the fact of a plant being discovered in the country of the Marsi. It is found growing also in the neighbourhood of the village of Nervesia, in the territory of the Æquicoli, and is known by the name of “consiligo.” It is very useful, as we shall have occasion to mention in the appropriate place, in cases of phthisis where recovery is considered more than doubtful.

Detailed table of contents

CHAP. 49.

THE IBERIS: SEVEN REMEDIES.

It is but very lately, too, that Servilius Democrates, one of our most eminent physicians, first called attention to a plant to which he gave the name of iberis, a fanciful appellation only, bestowed by him upon this discovery of his in the verses by him devoted to it. This plant is found mostly growing in the vicinity of ancient monuments, old walls, and overgrown footpaths: it is an evergreen, and its leaves are like those of nasturtium, with a stem a cubit in height, and a seed so diminutive as to be hardly perceptible; the root, too, has just the smell of nasturtium. Its properties are more strongly developed in summer, and it is only used freshgathered: there is considerable difficulty in pounding it.

Mixed with a small proportion of axle-grease, it is extremely useful for sciatica and all diseases of the joints; the application being kept on some four hours at the utmost, when used by the male sex, and about half that time in the case of females. Immediately after its removal, the patient must take a warm bath, and then anoint the body all over with oil and wine the same operation being repeated every twenty days, so long as there are any symptoms of pain remaining. A similar method is adopted for the cure of all internal defluxions; it is never applied, however, so long as the inflammation is at its height, but only when it has somewhat abated.

Detailed table of contents

CHAP. 50.

PLANTS WHICH HAVE BEEN DISCOVERED BY CERTAIN ANIMALS. CHELIDONIA: SIX REMEDIES.

The brute animals also have been the discoverers of certain plants: among them, we will name chelidonia first of all. It is by the aid of this plant that the swallow restores the sight of the young birds in the nest, and even, as some persons will have it, when the eyes have been plucked out. There are two varieties of this plant; the larger kind has a branchy stem, and a leaf somewhat similar to that of the wild parsnip, but larger. The plant itself is some two cubits in height, and of a whitish colour, that of the flower being yellow. The smaller kind has leaves like those of ivy, only rounder and not so white. The juice of it is pungent, and resembles saffron in colour, and the seed is similar to that of the poppy.

These plants blossom, both of them, at the arrival of the swallow, and wither at the time of its departure. The juice is extracted while they are in flower, and is boiled gently in a copper vessel on hot ashes, with Attic honey, being esteemed a sovereign remedy for films upon the eyes. This juice is employed also, unmixed with any other substance, for the eyesalves, which from it take their name of “chelidonia.”

Detailed table of contents

CHAP. 51.

THE DOG-PLANT: ONE REMEDY.

Dogs, too, are in the habit of seeking a certain plant, as a stimulant to the appetite; but although they eat it in our presence, it has never yet been discovered what it is, it being quite impossible to recognize it when seen half-chewed. There has also been remarked another bit of spitefulness in this animal, though in a much greater degree, in reference to another plant. When stung by a serpent, it cures itself, they say, by eating a certain herb, taking care, however, never to gather it in presence of man.

CHAP. 52.

THE ELAPHOBOSCON.

The hind, with a much greater degree of frankness, has discovered to us the elaphoboscon, a plant of which we have already spoken, and which is also called “helxine,” from the assistance it affords those animals in yeanning.

Detailed table of contents

CHAP. 53.

DICTAMNON: EIGHT REMEDIES. PSEUDODICTAMNON OR CHONDRIS. IN WHAT PLACES THE MOST POWERFUL PLANTS ARE FOUND. HOW THAT MILK IS DRUNK IN ARCADIA FOR THE BENEFICIAL EFFECTS OF THE PLANTS UPON WHICH THE CATTLE FEED.

It is the hind, too, that, as already stated, first made us acquainted with dictamnion, or dittany; for when wounded, it eats some of this plant, and the weapon immediately falls from the body. This plant grows nowhere but in Crete. The branches of it are remarkably thin; it resembles pennyroyal in appearance, and is hot and acrid to the taste. The leaves are the only part employed, it being destitute of blossom, seed, and stem: the root is thin., and never used. In Crete even, it is found growing only in a very limited locality, and is sought by goats with singular avidity.

In place of it, the pseudodictamnion is employed, a plant that is found growing in many countries. In leaf it is similar to the other, but the branches are more diminutive: by some persons it is known as "chondris." Its properties not being so strongly developed, the difference is immediately recognized: for an infusion of the very smallest piece of the real dittany, is sufficient to burn the mouth. The persons who gather it are in the habit of enclosing it in a stem of fennel-giant or in a reed, which they close at the ends that the virtues of it may not escape. Some persons say, that both plants grow indiscriminately in numerous localities, the inferior sort being the produce of rich soils, and the genuine dittany being found nowhere but in rugged, uncultivated spots.

There is, again, a third plant called "dictamnion," which, however, has neither the appearance nor the properties of the other plant so called; the leaves of it are like those of sisymbrium, but the branches are larger.

There has long been this impression with reference to Crete, that whatever plant grows there is infinitely superior in its properties to a similar plant the produce of any other country; the second rank being given to the produce of Mount Parnassus. In addition to this, it is generally asserted that simples of excellent quality are found upon Mount Pelion in Thessaly, Mount Teleuthrius in Eubœa, and throughout the whole of Arcadia and Laconia. Indeed, the Arcadians, they say, are in the habit of using, not the simples themselves, but milk, in the spring season more particularly; a period at which the field plants are swollen with juice, and the milk is medicated by their agency. It is cows' milk in especial that they use for this purpose, those animals being in the habit of feeding upon nearly every kind of plant. The potent properties of plants are manifested by their action upon four-footed animals in two very remarkable instances: in the vicinity of Abdera and the tract known as the Boundary of Diomedes, the horses, after pasturing, become inflamed with frantic fury; the same is the case, too, with the male asses, in the neighbourhood of Potniæ.

Detailed table of contents

CHAP. 54.

THE ARISTOLOCHIA, CLEMATITIS, CRETICA, PLISTOTO-CHIA, LOCHIA
POLYRRHIZOS, OR APPLE OF THE EARTH: TWENTY- TWO REMEDIES.

In the number of the most celebrated plants is the aristolochia, which would appear to have derived its name from females in a state of pregnancy, as being ἀρίστη λοχούσαιχ. Among us, however, it is known as the “malum terræ,” or apple of the earth, four different varieties of it being distinguished. One of these has a root covered with tubercles of a rounded shape, and leaves of a mixed appearance, between those of the mallow and the ivy, only softer and more swarthy. The second kind is the male plant, with an elongated root some four fingers in length, and the thickness of a walking-stick. A third variety is extremely thin and long, similar to a young vine in appearance: it has the most strongly-marked properties of them all, and is known by the additional names of “clematitis,” and “cretica.” All these plants are the colour of boxwood, have a slender stem, and bear a purple flower and small berries like those of the caper: the root is the only part that is possessed of any virtues.

There is also a fourth kind, the name given to which is “plistolochia;” it is more slender than the one last mentioned, has a root thickly covered with filaments, and is about as thick as a good-sized bulrush: another name given to it is “polyrrhizos.” The smell of all these plants is medicinal, but that of the one with an oblong root and a very slender stem, is the most agreeable: this last, in fact, which has a fleshy outer coat, is well adapted as an ingredient for nardine unguents even. They grow in rich champaign soils, and the best time for gathering them is harvest; after the earth is scraped from off them, they are put by for keeping.

The aristolochia that is the most esteemed, however, is that which comes from

Pontus; but whatever the soil may happen to be, the more weighty it is, the better adapted it is for medicinal purposes. The aristolochia with a round root is recommended for the stings of serpents, and that with an oblong root * * *

* But in this is centred its principal reputation; applied to the uterus with raw

beef, as a pessary, immediately after conception, it will ensure the birth of male issue, they say. The fishermen on the coasts of Campania give the round root the name of “poison of the earth;” and I myself have seen them pound it with lime, and throw it into the sea; immediately on which the fish flew towards it with surprising avidity, and being struck dead in an instant, floated upon the surface.

The kind that is known as “polyrrhizos,” is remarkably good, they say, for convulsions, contusions, and falls with violence, an infusion of the root being taken in water: the seed, too, is useful for pleurisy and affections of the sinews. It is considered, too, to be possessed of warming and strengthening

properties, similar to those of satyrion, in fact.

Detailed table of contents

CHAP. 55.

THE EMPLOYMENT OF THESE PLANTS FOR INJURIES INFLICTED BY SERPENTS.

But it will be as well now to mention the various uses made of these plants, and the effects produced by them, beginning with that most dangerous of all evils that can befall us, stings inflicted by serpents. In such cases the plant *britannica* effects a cure, and the same is the case with the root of all the varieties of panaces, administered in wine. The flower, too, and seed of panaces *chironion* are taken in drink, or applied externally with wine and oil: *cunila bubula*, too, is looked upon as particularly useful for this purpose, and the root of *polemonia* or *phileteris* is taken in doses of four drachmæ in unmixed wine. *Teucris*, *sideritis*, and *scordotis*, are used in wine, plants particularly good, all of them, for injuries inflicted by snakes; the juice or leaves, or else a decoction of them, being taken in drink or applied to the wound. For a similar purpose also, the root of the greater *centaury* is taken, in doses of one drachma to three cyathi of white wine. *Gentian*, too, is particularly good for the stings of snakes, taken either fresh or dried, in doses of two drachmæ, mixed with rue and pepper in six cyathi of wine. The odour, too, of *lysimachia* puts serpents to flight.

Chelidonia is also given in wine to persons who have been stung; and *betony* in particular is used as an external application to the wound, a plant the virtues of which are so extraordinary, it is said, that if a circle of it is traced around a serpent, it will lash itself to death with its tail. The seed of this plant is also administered in such cases, in doses of one denarius to three cyathi of wine; or else it is dried and powdered, and applied to the wound, in the proportion of three denarii of powder to one sextarius of water.

Cantabrica, *dittany*, and *aristolochia*, are also similarly used, one drachma of the root of this last plant being taken every now and then in a semisextarius of wine. It is very useful too, rubbed in with vinegar, and the same is the case, also, with *plistolochia*: indeed it will be quite sufficient to suspend this last over the hearth, to make all serpents leave the house.

[Detailed table of contents](#)

CHAP. 56. (9.)

THE ARIGEMONIA: FOUR REMEDIES.

The argemonia, too, is remedial in such cases; the root of it being taken, in doses of one denarius, in three cyathi of wine. It will be as well, however, to enter into some further details in reference to this plant and others, which I shall have occasion next to mention; it being my intention first to describe, under each head, those plants which are the most efficacious for the treatment of the affection under consideration.

The argemonia has leaves like those of the anemone, but divided like those of parsley: the head grows upon a slender stem resembling that of the wild poppy, and the root is also very similar to that of the same plant. The juice is of a saffron colour, acrid and pungent: the plant is commonly found in the fields of this country. Among us there are three varieties of it distinguished, the one being the most highly approved of, the root of which smells like frankincense.

[Detailed table of contents](#)

CHAP. 57.

AGARIC: THIRTY-THREE REMEDIES.

Agaric is found growing in the form of a fungus of a white colour, upon the trees in the vicinity of the Bosporus. It is administered in doses of four oboli, beaten up in two cyathi of oxymel. The kind that grows in Galatia is generally looked upon as not so efficacious. The male agaric is firmer than the other, and more bitter; it is productive too of head-ache. The female plant is of a looser texture; it has a sweet taste at first, which speedily changes into a bitter flavour.

Detailed table of contents

CHAP. 58.

THE ECHIOS; THREE VARIETIES OF IT: TWO REMEDIES.

Of the echios there are two kinds; one of which resembles pennyroyal in appearance, and has a concave leaf. It is administered, in doses of two drachmæ, in four cyathi of wine. The other kind is distinguished by a prickly down, and bears small heads resembling those of vipers: it is usually taken in wine and vinegar. Some persons give the name of “echios personata” to a kind of echios with larger leaves than the others, and burrs of considerable size, resembling that of the lappa. The root of this plant is boiled and administered in vinegar.

Henbane, pounded with the leaves on, is taken in wine, for the sting of the asp in particular.

Detailed table of contents

CHAP. 59.

HIERABOTANE, PERISTEREON, OR VERBENACA; TWO VARIETIES OF IT: TEN REMEDIES.

But among the Romans there is no plant that enjoys a more extended renown than hierabotane, known to some persons as “peristereon,” and among us more generally as “verbenaca.” It is this plant that we have already mentioned as being borne in the hands of envoys when treating with the enemy, with this that the table of Jupiter is cleansed, with this that houses are purified and due expiation made. There are two varieties of it: the one that is thickly covered with leaves is thought to be the female plant; that with fewer leaves, the male. Both kinds have numerous thin branches, a cubit in length, and of an angular form. The leaves are smaller than those of the quercus, and narrower, with larger indentations. The flower is of a grey colour, and the root is long and thin. This plant is to be found growing everywhere, in level humid localities. Some persons make no distinction between these two varieties, and look upon them as identical, from the circumstance of their being productive of precisely similar effects.

The people in the Gallic provinces make use of them both for soothsaying purposes, and for the prediction of future events; but it is the magicians more particularly that give utterance to such ridiculous follies in reference to this plant. Persons, they tell us, if they rub themselves with it will be sure to gain the object of their desires; and they assure us that it keeps away fevers, conciliates friendship, and is a cure for every possible disease; they say, too, that it must be gathered about the rising of the Dog-star — but so as not to be shone upon by sun or moon — and that honey-combs and honey must be first presented to the earth by way of expiation. They tell us also that a circle must first be traced around it with iron; after which it must be taken up with the left hand, and raised aloft, care being taken to dry the leaves, stem, and root, separately in the shade. To these statements they add, that if the banqueting couch is sprinkled with water in which it has been steeped, merriment and hilarity will be greatly promoted thereby.

As a remedy for the stings of serpents, this plant is bruised in wine.

Detailed table of contents

CHAP. 60.

THE BLATTARIA: ONE REMEDY.

There is a plant very similar in appearance to verbascum, so much so, indeed, as to be frequently gathered for it by mistake. The leaves, however, are not so white, the stems are more numerous, and the flower is of a yellow colour. Thrown upon the ground, this plant attracts black beetles to it, whence its Roman appellation “blattaria.”

Detailed table of contents

CHAP. 61.

LEMONIUM : ONE REMEDY.

Lemonium furnishes a milky juice, which thickens like gum. It grows in moist, watery localities, and is generally administered, in doses of one denarius, in wine.

[Detailed table of contents](#)

CHAP. 62.

QUINQUEFOLIUM, KNOWN ALSO AS PENTAPETES, PEN- TAPHYLLON, OR
CHAMÆZELON: THIRTY-THREE REMEDIES.

There is no one to whom quinquefolium is unknown, being recommended by a sort of strawberry which it bears: The Greeks give it the name of pentapetes, pentaphyllon, and Chammæzelon. The root, when taken up, is red; but as it dries it becomes black and angular. Its name is derived from the number of its leaves: it puts forth and withers with the leaves of the vine. This plant also is employed in the purification of houses.

Detailed table of contents

CHAP. 63.

THE SPARGANION : ONE REMEDY.

The root, too, of the plant known as the sparganion, is taken in white wine, as a remedy for the stings of serpents.

[Detailed table of contents](#)

CHAP. 64.

FOUR VARIETIES OF THE DAUCUS: EIGHTEEN REMEDIES.

Petronius Diodotus has distinguished four kinds of daucus, which it would be useless here to describe, the varieties being in reality but two in number. The most esteemed kind is that of Crete, the next best being the produce of Achaia, and of all dry localities. It resembles fennel in appearance, only that its leaves are whiter, more diminutive, and hairy on the surface. The stem is upright, and a foot in length, and the root has a remarkably pleasant taste and smell. This kind grows in stony localities with a southern aspect.

The inferior sorts are found growing everywhere, upon declivities for instance, and in the hedges of fields, but always in a rich soil. The leaves are like those of coriander, the stem being a cubit in length, the heads round, often three or more in number, and the root ligneous, and good for nothing when dry. The seed of this kind is like that of cummin, while that of the first kind bears a resemblance to millet; in all cases it is white, acrid, hot, and odoriferous. The seed of the second kind has more active properties than that of the first; for which reason it should be used more sparingly.

If it is considered really desirable to recognize a third variety of the daucus, there is a plant of this nature very similar to the staphylinos, known as the “pastinaca erratica,” with an oblong seed and a sweet root. Quadrupeds will touch none of these plants, either in winter or in summer, except indeed, after abortion. The seed of the various kinds is used, with the exception of that of Crete, in which case it is the root that is employed; this root being particularly useful for the stings of serpents. The proper dose is one drachma, taken in wine. It is administered also to cattle when stung by those reptiles.

Detailed table of contents

CHAP. 65.

THE THERIONARCA: TWO REMEDIES.

The therionarca, altogether a different plant from that of the Magi, grows in our own climates, and is a branchy plant, with greenish leaves, and a rose-coloured flower. It has a deadly effect upon serpents, and the very contact of it is sufficient to benumb a wild beast, of whatever kind it be.

Detailed table of contents

CHAP. 66.

THE PERSOLATA OR ARCION; EIGHT REMEDIES.

The persolata, a plant known to every one, and called “arcion” by the Greeks, has a leaf, larger, thicker, more swarthy, and more hairy than that of the gourd even, with a large white root. This plant also is taken, in doses of two denarii, in wine.

Detailed table of contents

CHAP. 67.

CYCLAMINOS OR TUBER TERRÆ: TWELVE REMEDIES.

So too, the root of cyclaminos is good for injuries inflicted by serpents of all kinds. It has leaves smaller than those of ivy, thinner, more swarthy, destitute of angles, and covered with whitish spots. The stem is thin and hollow, the flowers of a purple colour, and the root large and covered with a black rind; so much so, in fact, that it might almost be taken for the root of rape. This plant grows in umbrageous localities, and by the people of our country is known as the “tuber terræ.” It ought to be grown in every house, if there is any truth in the assertion that wherever it grows, noxious spells can have no effect. This plant is also what is called an “amulet;” and taken in wine, they say, it produces all the symptoms and appearances of intoxication. The root is dried, cut in pieces, like the squill, and put away for keeping. When wanted, a decoction is made of it, of the consistency of honey. Still, however, it has some deleterious properties; and a pregnant woman, it is said, if she passes over the root of it, will be sure to miscarry.

Detailed table of contents

CHAP. 68.

THE CYCLAMINOS CISSANTHEMOS: FOUR REMEDIES.

There is also another kind of cyclaminos, known by the additional name of “cissanthemos;” the stems of it, which are jointed, are good for nothing. It is altogether different from the preceding plant, and entwines around the trunks of trees. It bears a berry similar to that of the ivy, but soft; and the flower is white and pleasing to the sight. The root is never used. The berries are the only part of it in use, being of an acrid, viscous taste. They are dried in the shade, after which they are pounded and divided into lozenges.

[Detailed table of contents](#)

CHAP. 69.

THE CYCLAMINOS CHAMÆCISOS: THREE REMEDIES.

A third kind of cyclaminos has also been shown to me, the additional name of which is “chamæcissos.” It consists of but a single leaf, with a branchy root, formerly employed for killing fish.

Detailed table of contents

CHAP. 70.

PEUCEDANUM: TWENTY-EIGHT REMEDIES.

But in the very first rank among these plants, stands peucedanum, the most esteemed kind of which is that of Arcadia, the next best being that of Samothrace. The stem resembles that of fennel, is thin and long, covered with leaves close to the ground, and terminating in a thick black juicy root, with a powerful smell. It grows on umbrageous mountains, and is taken up at the end of autumn. The largest and tenderest roots are the most esteemed; they are cut with bone-knives into slips four fingers in length, and left to shed their juice in the shade; the persons employed taking the precaution of rubbing the head and nostrils with rose-oil, as a preservative against vertigo.

There is also another kind of juice, which adheres to the stems, and exudes from incisions made therein. It is considered best when it has arrived at the consistency of honey: the colour of it is red, and it has a strong but agreeable smell, and a hot, acrid taste. This juice, as well as the root and a decoction of it, enters into the composition of numerous medicaments, but the juice has the most powerful properties of the two. Diluted with bitter almonds or rue, it is taken in drink as a remedy for injuries inflicted by serpents. Rubbed upon the body with oil, it is a preservative against the attacks of those reptiles.

[Detailed table of contents](#)

CHAP. 71. (10.)

EBULUM : SIX REMEDIES.

A fumigation, too, of ebulum, a plant known to every one, will put serpents to flight.

[Detailed table of contents](#)

CHAP. 72.

POLEMONIA: ONE REMEDY.

The root of polemonia even worn as an amulet only, is particularly useful for repelling the attacks of scorpions, as also the phalangium and other small insects of a venomous nature. For injuries inflicted by the scorpion, aristolochia is also used, or agaric, in doses of four oboli to four cyathi of wine. For the bite of the phalangium, vervain is employed, in combination with wine or oxycrate: cinquefoil, too, and daucus, are used for a similar purpose.

[Detailed table of contents](#)

CHAP. 73.

PHLOMOS OR VERBASCUM: FIFTEEN REMEDIES.

Verbascum has the name of “phlomos” with the Greeks. Of this plant there are two principal kinds; the white, which is considered to be the male, and the black, thought to be the female. There is a third kind, also, which is only found in the woods. The leaves of these plants are larger than those of the cabbage, and have a hairy surface: the stem is upright, and more than a cubit in height, and the seed black, and never used. The root is single, and about the thickness of the finger. The two principal kinds are found growing in champaign localities. The wild verbascum has leaves like those of elelisphacus, but of an elongated form; the branches are ligneous.

Detailed table of contents

CHAP. 74.

THE PHLOMIS: ONE REMEDY. THE LYCHNITIS OR THRYALLIS.

There are also two varieties of the phlomis, hairy plants, with rounded leaves, and but little elevated above the surface of the earth. A third kind, again, is known as the “lychnitis” by some persons, and as the “thryallis” by others: it has three leaves only, or four at the very utmost, thick and unctuous, and well adapted for making wicks for lamps. The leaves of the phlomos which we have mentioned as the female plant, if wrapped about figs, will preserve them most efficiently from decay, it is said. It seems little better than a loss of time to give the distinguishing characteristics of these three kinds, the effects of them all being precisely the same.

For injuries inflicted by scorpions, an infusion of the root is taken, with rue, in water. Its bitterness is intense, but it is quite as efficacious as the plants already mentioned.

[Detailed table of contents](#)

CHAP. 75.

THE THELYPHONON OR SCORPIO: ONE REMEDY.

The thelyphonon is a plant known as the “scorpio” to some, from the peculiar form of its roots, the very touch of which kills the scorpion: hence it is that it is taken in drink for stings inflicted by those reptiles. If a dead scorpion is rubbed with white hellebore, it will come to life, they say. The thelyphonon is fatal to all quadrupeds, on the application of the root to the genitals. The leaf too, which bears a resemblance to that of cyclaminos, is productive of a similar effect, in the course of the same day. It is a jointed plant, and is found growing in unbrageous localities. Juice of betony or of plantago is a preservative against the venom of the scorpion.

Detailed table of contents

CHAP. 76.

THE PHLYNION, NEURAS, OR POTERION ; ONE REMEDY.

Frogs, too, have their venom, the bramble-frog in particular, and I myself have seen the Psylli, in their exhibitions, irritate them by placing them upon flat vessels made red hot, their bite being fatal more instantaneously than the sting even of the asp. One remedy for their poison is the phrynion, taken in wine, which has also the additional names of “neuras” and “poterion:” it bears a small flower, and has numerous fibrous roots, with an agreeable smell.

[Detailed table of contents](#)

CHAP. 77.

THE ALISMA, DAMASONION, OR LYRON: SEYENTEEN REMEDIES

Similar, too, are the properties of the alisma, known to some persons as the “danmasonion,” and as the “lyron” to others. The leaves of it would be exactly those of the plantago, were it not that they are narrower, more jagged at the edges, and bent downwards in a greater degree. In other respects, they present the same veined appearance as those of the plantago. This plant has a single stern, slender, a cubit in height, and terminated by a spreading head. The roots of it are numerous, thin like those of black hellebore, acrid, unctuous, and odoriferous: it is found growing in watery localities.

There is another kind also, which grows in the woods, of a more swarthy colour, and with larger leaves. The root of them both is used for injuries inflicted by frogs and by the sea-hare, in doses of one drachma taken in wine. Cyclaminos, too, is an antidote for injuries inflicted by the sea-hare.

The bite of the mad dog has certain venomous properties, as an antidote to which we have the cynorrhodos, of which we have spoken elsewhere already. The plantago is useful for the bites of all kinds of animals, either taken in drink or applied topically to the part affected. Betony is taken on similar occasions, in old wine, unmixed.

Detailed table of contents

CHAP. 78.

PERISTEREOS: SIX REMEDIES.

The name of peristereos is given to a plant with a tall stem, covered with leaves, and throwing out other stems from the top. It is much sought by pigeons, to which circumstance it owes its name. Dogs will never bark, they say, at persons who have this plant about them.

[Detailed table of contents](#)

CHAP. 79.

REMEDIES AGAINST CERTAIN POISONS.

Closely approaching in their nature to these various kinds of poisons, are those which have been devised by man for his own destruction. In the number of antidotes to all these artificial poisons as well as to the spells of sorcery, the very first place must be accorded to the moly of Homer; next to which come the mithridatia, scordotis, and centaury. The seed of betony carries off all kinds of noxious substances by stool; being taken for the purpose in honied wine or raisin wine, or else pulverized, and taken, in doses of one drachma, in four cyathi of old wine: in this last case, however, the patient must bring it off the stomach by vomit and then repeat the dose. Persons who accustom themselves to take this plant daily, will never experience any injury, they say, from substances of a poisonous nature.

When a person has taken poison, one most powerful remedy is aristolochia, taken in the same proportions as those used for injuries inflicted by serpents. The juice, too, of cinquefoil is given for a similar purpose; and in both cases, after the patient has vomited, agaric is administered, in doses of one denarius, in three cyathi of hydromel.

Detailed table of contents

CHAP. 80.

THE ANTIRREHINUM, ANARRHINON, OR LYCHNIS AGRIA: THREE REMDIES.

The name of antirrhinum or anarrhinon is given to the lychnis agria, a plant which resembles flax in appearance, is destitute of root, has a flower like that of the hyacinth, and a seed similar in form to the muzzle of a calf. According to what the magicians say, persons who rub themselves with this plant improve their personal appearance thereby; and they may ensure themselves against all noxious substances and poisons, by wearing it as a bracelet.

Detailed table of contents

CHAP. 81.

EUCLEA: ONE EBMEDY.

The same is the case, too, with the plant to which they give the name of “euclea,” and which, they tell us, rubbed upon the person, will ensure a more extended consideration. They say, too, that if a person carries artemisia about him, he will be ensured against all noxious drugs, the attacks of wild beasts of every kind, and sunstroke even. This last plant is taken also in wine, in cases of poisoning by opium. Used as an amulet, or taken in drink, it is said to be particularly efficacious for injuries inflicted by frogs.

Detailed table of contents

CHAP. 82.

TIE PERICARPUM; TWO VARIETIES OF IT: TWO REMEDIES.

The pericarpum is a kind of bulbous plant. There are two varieties of it; one with a red outer coat, and the other, similar in appearance to the black poppy, and possessed of greater virtues than the first. They are both, however, of a warming nature, for which reason they are administered to persons who have taken hemlock, a poison for which frankincense and panaces are used, chironion in particular. This last, too, is given in cases of poisoning by fungi.

[Detailed table of contents](#)

CHAP. 83. (11.)

REMEDIES FOR DISEASES OF THE HEAD. NYMPHÆA HERACLIA: TWO REMEDIES.

But we shall now proceed to point out the various classes of remedies for the several parts of the body, and the maladies to which those parts are subject, beginning in the first place with the head.

The root of nymphæa heraclia effects the cure of alopecia, if they are beaten up together, and applied. The polythrix differs from the callitrichos in having white, rushlike suckers, larger leaves, and more numerous; the main stem, too, is larger. This plant strengthens the hair, prevents it from falling off, and makes it grow more thickly.

Detailed table of contents

CHAP. 84.

THE LINGULACA : ONE REMEDY.

The same is the case too with the lingulaca, a plant that grows in the vicinity of springs, and the root of which is reduced to ashes, and beaten up with hog's lard. Due care must be taken, however, that it is the lard of a female, of a black colour, and one that has never farrowed. Tile application is rendered additionally efficacious, if the ointment is applied in the sun. Root, too, of cyclaminos is employed in the same manner for a similar purpose. A decoction of root of hellebore in oil or in water is used for the removal of porrigo. For the cure of head-ache, root of all kinds of panaces is used. beaten up in oil; as also aristolochia and iberis, this last being applied to the head for an hour or more, if the patient can; bear it so long, care being taken to bathe in the meanwhile. The daucus, too, is curative of head-ache. Cyclasininos, introduced into the nostrils with honey, clears the head: used in the form of a liniment, it heals ulcers of the head. Peristereos, also, is curative of diseases of the head.

[Detailed table of contents](#)

CHAP. 85.

THE CACALIA OR LEONTICE: THREE REMEDIES.

The name of “cacalia” or “leontice” is given to a plant with seed resembling small pearls in appearance, and hanging down between large leaves: it is mostly found upon mountains. Fifteen grains of this seed are macerated in oil, and the head is rubbed with the mixture, the contrary way to the hair.

Detailed table of contents

CHAP. 86.

THE CALLITRICHOS: ONE REMEDY.

A sternutatory, too, is prepared from the callitrichos. The leaves of this plant are similar to those of the lentil, and the stems resemble fine rushes; the root is very diminutive. It grows in shady, moist localities, and has a burning taste in the mouth.

[Detailed table of contents](#)

CHAP. 87.

HYSSOP: TEN REMEDIES.

Hyssop, beaten up in oil, is curative of phthiriasis and prurigo of the head. The best hyssop is that of Mount Taurus in Cilicia, next to which in quality is the produce of Pamphylia and Smyrna. This plant is injurious to the stomach: taken with figs, it produces alvine evacuations, and used in combination with honey, it acts as an emetic. It is generally thought that, beaten up with honey, salt, and cum- min, it is curative of the stings of serpents.

[Detailed table of contents](#)

CHAP. 88.

THE LONCHITIS : FOUR REMEDIES.

The lonchitis is not, as most writers have imagined, the same plant as the xiphion or phasganion, although the seed of it does bear a resemblance to the point of a spear. The lonchitis, in fact, has leaves like those of the leek, of a reddish colour near the root, and more numerous there than on the upper part of the stem. It bears diminutive heads, which are very similar to our masks of comedy, and from which a small tongue protrudes: the roots of it are remarkably long. It grows in thirsty, arid soils.

[Detailed table of contents](#)

CHAP. 89.

THE XIPHION OR PHASGANION: FOUR REMEDIES.

The xiphion or phasganion, on the other hand, is found growing in humid localities. On first leaving the ground it has the appearance of a sword; the stem of it is two cubits in length, and the root is fringed like a hazel nut.

This root should always be taken up before harvest, and dried in the shade. The upper part of it, pounded with frankincense, and mixed with an equal quantity of wine, extracts fractured bones of the cranium, purulent matter in all parts of the body, and bones of serpents, when accidentally trodden upon; it is very efficacious, too, for poisons. In cases of head-ache, the head should be rubbed with hellebore, boiled and beaten up in olive oil, or oil of roses, or else with peucedanum steeped in olive oil or rose oil, and vinegar. This last plant, made lukewarm, is very good also for hemicrania and vertigo. It being of a heating nature, the body is rubbed with the root as a sudorific.

[Detailed table of contents](#)

CHAP. 90.

PSYLLION, CYNOÏDES, CRYSTALLION, SICELICON, OR CYNOMYIA; SIXTEEN
REMEDIES. TIRYSELINUM: ONE REMEDY.

Psyllion, cynoïdes, crystallion, sicelicon, or cynomyia, has a slender root, of which no use is made, and numerous thin branches, with seeds resembling those of the bean, at the extremities. The leaves of it are not unlike a dog's head in shape; and the seed, which is enclosed in berries, bears a resemblance to a flea — whence its name “psyllion.” This plant is generally found growing in vineyards, is of a cooling nature, and is extremely efficacious as a dispellent. The seed of it is the part made use of; for head-ache, it is applied to the forehead and temples with rose oil and vinegar, or else with oxycrate; it is used as a liniment for other purposes also. Mixed in the proportion of one acetabulum to one sextarius of water, it is left to coagulate and thicken; after which it is beaten up, and the thick solution is used as a liniment for all kinds of pains, abscesses, and inflammations.

Aristolochia is used as a remedy for wounds in the head; it has the property, too, of extracting fractured bones, not only from other parts of the body, but the cranium in particular. The same, too, with plistolochia.

Thryselinum is a plant not unlike parsley; the root of it, eaten, carries off pituitous humours from the head.

Detailed table of contents

CHAP. 91. (12.)

REMEDIES FOR DISEASES OF THE EYES.

It is generally thought that the greater centaury strengthens the sight, if the eyes are fomented with it steeped in water; and that by employing the juice of the smaller kind, in combination with honey, films and cloudiness may be dispersed, marks obliterated, and small flies removed which have got into the eye. It is thought also that sideritis is curative of albugo in beasts of burden. As to chelidonia, it is marvellously good for all the affections above mentioned. Root of panaces is applied, with polenta, to defluxions of the eyes; and for the purpose of keeping them down, henbane-seed is taken, in doses of one obolus, with an equal proportion of opium, in wine. Juice, too, of gentian is used as a lini- ment, and it sometimes forms an ingredient in the more active eyesalves, as a substitute for meconium. Euphorbia, applied in the form of a liniment, improves the eyesight, and for ophthalmia juice of plantago is injected into the eyes.

Aristolochia disperses films upon the eyes; and iberis, attached to the head with cinquefoil, is curative of defluxions and other diseases of the eyes. Verbascum is applied topically to defluxions of the eyes, and vervain is used for a similar purpose, with rose oil and vinegar. For the treatment of cataract and dimness of sight, cyclaminos is reduced to a pulp and divided into lozenges. Juice, too, of peu- cedanum, as already mentioned, mixed with meconium and oil of roses, is good for the sight, and disperses films upon the eyes. Psyllion, applied to the forehead, arrests defluxions of the eyes.

Detailed table of contents

CHAP. 92. (13.)

THE ANAGALLIS, OR CORCHORON; TWO VARIE- TIES OF IT: SIX REMEDIES.

The anagallis is called “corchoron” by some. There are two kinds of it, the male plant, with a red blossom, and the female, with a blue flower. These plants do not exceed a palm in height, and have a tender stem, with diminutive leaves of a rounded form, drooping upon the ground. They grow in gardens and in spots covered with water, the blue anagallis being the first to blossom. The juice of either plant, applied with honey, disperses films upon the eyes, suffusions of blood in those organs resulting from blows, and argema with a red tinge: if used in combination with Attic honey, they are still more efficacious. The anagallis has the effect also of dilating the pupil; hence the eye is anointed with it before the operation of couching for cataract. These plants are employed also for diseases of the eyes in beasts of burden.

The juice, injected into the nostrils, which are then rinsed with wine, acts as a detergent upon the head: it is taken also, in doses of one drachma, in wine, for wounds inflicted by serpents. It is a remarkable fact, that cattle will refuse to touch the female plant; but if it should so happen that, deceived by the resemblance — the flower being the only distinguishing mark — they have accidentally tasted it, they immediately have recourse, as a remedy, to the plant called “asylla,” but more generally known among us as “ferus oculus.” Some persons recommend those who gather it, to prelude by saluting it before sunrise, and then, before uttering another word, to take care and extract the juice immediately if this is done, they say, it will be doubly efficacious.

As to the juice of euphorbia, we have spoken of its properties at sufficient length already. In cases of ophthalmia, attended with swelling, it will be a good plan to apply wormwood beaten up with honey, as well as powdered betony.

Detailed table of contents

CHAP. 93.

THE ÆGILOPS : TWO REMEDIES.

The fistula of the eye, called “ægilops,” is cured by the agency of the plant of the same name, which grows among barley, and has a leaf like that of wheat. The seed is pounded for the purpose, and applied with meal; or else the juice is extracted from the stem and more pulpy leaves, the ears being first removed. This juice is incorporated with meal of three-month wheat, and divided into lozenges.

Detailed table of contents

CHAP. 94.

MANDRAGORA, CIRCÆON, MORION, OR HIPPOPHLOMOS; TWO VARIETIES OF IT: TWENTY-FOUR REMEDIES.

Some persons, too, were in the habit of employing mandragora for diseases of the eyes; but more recently the use of it for such a purpose has been abandoned. It is a well-ascertained fact, however, that the root, beaten up with rose oil and wine, is curative of defluxions of the eyes and pains in those organs; and, indeed, the juice of this plant still forms an ingredient in many medicaments for the eyes. Some persons give it the name of “circæon.” There are two varieties, the white mandragora, which is generally thought to be the male plant, and the black, which is considered to be the female. It has a leaf narrower than that of the lettuce, a hairy stem, and a double or triple root, black without and white within, soft and fleshy, and nearly a cubit in length.

Both kinds bear a fruit about the size of a hazel-nut, enclosing a seed resembling the pips of a pear in appearance. The name given to the white plant by some persons is “arsen,” by others “morion,” and by others again, “hippophlomos.” The leaves of it are white, while those of the other one are broader, and similar to those of garden lapathum in appearance. Persons, when about to gather this plant, take every precaution not to have the wind blowing in their face; and, after tracing three circles round it with a sword, turn towards the west and dig it up. The juice is extracted both from the fruit and from the stalk, the top being first removed; also from the root, which is punctured for the purpose, or else a decoction is made of it. The filaments, too, of the root are made use of, and it is sometimes cut up into segments and kept in wine.

It is not the mandragora of every country that will yield a juice, but where it does, it is about vintage time that it is collected: it has in all cases a powerful odour, that of the root and fruit the most so. The fruit is gathered when ripe, and dried in the shade; and the juice, when extracted, is left to thicken in the sun. The same is the case, too, with the juice of the root, which is extracted either by pounding it or by boiling it down to one third in red wine. The leaves are best, kept in brine; indeed, when fresh, the juice of them is a baneful poison, and these noxious properties are far from being entirely removed, even when they are preserved in brine. The very odour of them is highly oppressive to the head, although there are countries in which the fruit is eaten. Persons ignorant of its properties are apt to be struck dumb by the odour of this plant when in excess, and too strong a dose of the juice is productive of fatal effects.

Administered in doses proportioned to the strength of the patient, this juice has a narcotic effect; a middling dose being one cyathus. It is given, too, for injuries inflicted by serpents, and before incisions or punctures are made in the body, in order to ensure insensibility to the pain. Indeed, for this last

purpose, with some persons, the odour of it is quite sufficient to induce sleep. The juice is taken also as a substitute for hellebore, in doses of two oboli, in honied wine: hellebore, however, is more efficacious as an emetic, and as an evacuant of black bile.

Detailed table of contents

CHAP. 95.

HEMLOCK: THIRTEEN REMEDIES.

Hemlock, too, is a poisonous plant, rendered odious by the use made of it by the Athenian people, as an instrument of capital punishment: still, however, as it is employed for many useful purposes, it must not be omitted. It is the seed that is noxious, the stalk being eaten by many people, either green, or cooked in the saucepan. This stem is smooth, jointed like a reed, of a swarthy hue, often as much as two cubits in height, and branchy at the top. The leaves are like those of coriander, only softer, and possessed of a powerful odour. The seed is more substantial than that of anise, and the root is hollow and never used. The seed and leaves are possessed of refrigerating properties; indeed, it is owing to these properties that it is so fatal, the cold chills with which it is attended commencing at the extremities. The great remedy for it, provided it has not reached the vitals, is wine, which is naturally of a warming tendency; but if it is taken in wine. it is irremediably fatal.

A juice is extracted from the leaves and flowers; for it is at the time of its blossoming that it is in its full vigour. The seed is crushed, and the juice extracted from it is left to thicken in the sun, and then divided into lozenges. This preparation proves fatal by coagulating the blood — another deadly property which belongs to it; and hence it is that the bodies of those who have been poisoned by it are covered with spots. It is sometimes used in combination with water as a medium for diluting certain medicaments. An emollient poultice is also prepared from this juice, for the purpose of cooling the stomach; but the principal use made of it is as a topical application, to check defluxions of the eyes in summer, and to allay pains in those organs. It is employed also as an ingredient in eyesalves, and is used for arresting fluxes in other parts of the body: the leaves, too, have a soothing effect upon all kinds of pains and tumours, and upon defluxions of the eyes.

Anaxilaüs makes a statement to the effect, that if the mamillæ are rubbed with hemlock (luring virginity, they will always be hard and firm: but a better-ascertained fact is, that applied to the mamillæ, it dries up the milk in women recently delivered; as also that, applied to the testes at the age of puberty, it acts most effectually as an antaphrodisiac. As to those cases in which it is recommended to take it internally as a remedy, I shall, for my own part, decline to mention them. The most powerful hemlock is that grown at Susa, in Parthia, the next best being the produce of Laconia, Crete, and Asia. In Greece, the hemlock of the finest quality is that of Megara, and next to it, that of Attica.

CHAP. 96.

CRETHMOS AGRIOS : ONE REMEDY.

Crethmos agrios, applied to the eyes, removes rheum; and, with the addition of polenta, it causes tumours to disappear.

Detailed table of contents

CHAP. 97.

MOLYBDÆNA: ONE REMEDY.

Molybdæna also grows everywhere in the fields, a plant commonly known as “plumbago.” It has leaves like those of lapathum, and a thick, hairy root. Chewed and applied to the eye from time to time, it removes the disease called “plumbum,” which affects that organ.

[Detailed table of contents](#)

CHAP. 98.

THE FIRST KIND OF CAPNOS, KNOWN ALSO AS CHICKEN'S FOOT: ONE
REMEDY.

The first kind of capnos, known also as “chicken’s foot,” is found growing on walls and hedges: it has very thin, straggling branches, with a purple blossom. It is used in a green state, and the juice of it disperses films upon the eyes; hence it is that it is employed as an ingredient in medicinal compositions for the eyes.

Detailed table of contents

CHAP. 99.

THE ARBORESCENT CAPNOS: THREE REMEDIES.

There is another kind of capnos also, similar both in name and properties, but different in appearance. It is a branchy plant, is extremely delicate, has leaves like those of coriander, is of an ashy colour, and bears a purple flower: it grows in gardens, and amid crops of barley. Employed in the form of an ointment for the eyes, it improves the sight, producing tears in the same way that smoke does, to which, in fact, it owes its name. It has the effect also of preventing the eyelashes, when pulled out, from growing again.

[Detailed table of contents](#)

CHAP. 100.

THE ACORON OR AGRION: FOURTEEN REMEDIES.

The acoron has leaves similar to those of the iris, only narrower, and with a longer stalk; the roots of it are black, and not so veined, but in other respects are similar to those of the iris, have an acrid taste and a not unpleasant smell, and act as a carminative. The best roots are those grown in Pontus, the next best those of Galatia, and the next those of Crete; but it is in Colchis, on the banks of the river Phasis, and in various other watery localities, that they are found in the greatest abundance, When fresh, they have a more powerful odour than when kept for some time: these of Crete are more blanched than the produce of Pontus. They are cut into pieces about a finger in length, and dried in leather bags in the shade.

There are some authors who give the name of “acoron” to the root of the oxymysine; for which reason also some prefer giving that plant the name of “acorion.” It has powerful properties as a calorific and resolvent, and is taken in drink for cataract and films upon the eyes; the juice also is extracted, and taken for injuries inflicted by serpents.

Detailed table of contents

CHAP. 101.

THE COTYLEDON: TWO VARIETIES OF IT: SIXTY-ON, REMEDIES.

The cotyledon is a small herbaceous plant, with a diminutive, tender stem, and an unctuous leaf, with a concave surface like that of the cotyloïd cavity of the thigh. It grows in maritime and rocky localities, is of a green colour, and has a rounded root like an olive: the juice of it is remedial for diseases of the eyes.

There is another kind also of the same plant, the leaves of which are of a dirty green colour, larger than those of the other, and growing in greater numbers about the root, which is surrounded with them just as the eye is with the socket. These leaves have a remarkably astringent taste, and the stem is of considerable length, but extremely slender. This plant is employed for the same purposes as the iris and aizôüm.

Detailed table of contents

CHAP. 102.

THE GREATER AIZOÛM, ALSO CALLED BUPHTHALMOS, ZOÖPHTHALMOS, STERGETHRON, HYPOGESON, AMBROSION, AME- RIMNON, SEDTUM MAGNUM, OR DIGITELLUS: THIRTY-SIX REMIIE- DIES. TIHE SMALLER AIZOÛM, ALSO CALLED ERITHALES, TRI- THALES, CHRYSOTHALES, ISOETES OR SEDUM: THIRTY-TWO REMEDIES.

Of the plant known as aizoûm there are two kinds; the larger of which is sown in earthen pots. By some persons it is known as “bupthalmos,” and by others as “zoöpthalmos,” or else as stergethron,” because it forms an ingredient in the composition of philtres. Another name given to it is “hypogeson,” from the circumstance that it generally grows upon the eaves of houses: some persons, again, give it the names of “ambrosion” and “amerimnon.” In Italy it is known as “sedum magnum,” “oculus,” or “digitellus.” The other kind of aizoûm is more diminutive, and is known by some persons as “erithales” and by others as “trithales,” from the circumstance that it blossoms three times in the year. Other names given to it are “chrysothales” and “isoêtes:” but aizoûm is the colmmon appellation of them both, from their being always green.

The larger kind exceeds a cubit in height, and is somewhat thicker than the thumb: at the extremity, the leaves are simi- lar to a tongue in shape, and are fleshy, unctuous, full of juice, and about as broad as a person’s thumb. Some are bent downwards towards the ground, while others again stand upright, the outline of them resembling an eye in shape. The smaller kind grows upon walls, old rubbish of houses, and tiled roof,; it is branchy from the root, anti covered with leaves to the extremity. These leaves are narrow, pointed, and juicy: the stem is a palm in height, and the root is never used.

Detailed table of contents

CHAP. 103.

THE ANDRACHLE AGRIA OR ILLECEBRA: THIRTY-TWO REMEDIES.

A similar plant is that known to the Greeks by the name of “andrachle agria,” and by the people of Italy as the “illece- bra.” Its leaves, though small, are larger than those of the last-named plant, but growing on a shorter stem. It grows in craggy localities, and is gathered for use as food. All these plants have the same properties, being cooling and astringent. The leaves, applied topically, or the juice, in form of a liniment, are curative of defluxions of the eyes: this juice too acts as a detergent upon ulcers of the eyes, makes new flesh, and causes them to cicatrize; it cleanses the eyelids also of viscous matter. Applied to the temples, both the leaves and the juice of these plants are remedial for head-ache; they neutralize the venom also of the phalangium; and the greater aizöüm, in particular, is an antidote to aconite. It is asserted, too, that those who carry this last plant about them will never be stung by the scorpion.

These plants are curative of pains in the ears; which is the case also with juice of henbane, applied in moderate quantities, of achillea, of the smaller centaury and plantago, of peucedanum in combination with rose-oil and opium, and of acoron mixed with rose-leaves. In all these cases, the liquid is made warm, and introduced into the ear with the aid of a syringe. The cotyledon is good, too, for suppurations in the ears, mixed with deer’s marrow made hot. The juice of pounded root of ebulum is strained through a linen cloth, and then left to thicken in the sun: when wanted for use, it is moistened with oil of roses, and made hot, being employed for the cure of imposthumes of the parotid glands. Vervain and plantago are likewise used for the cure of the same malady, as also sideritis, mixed with stale axle-grease.

Detailed table of contents

CHAP. 104.

A REMEDY FOR DISEASES OF THE NOSTRILS.

Aristolochia, mixed with cyperus, is curative of polypus of the nose.

Detailed table of contents

CHAP. 105.

REMEDIES FOR DISEASES OF THE TEETH.

The following are remedies for diseases of the teeth: root of panaces, chewed, that of the chironion in particular, and juice of panaces, used as a collutory; root, too, of henbane, chewed with vinegar, and root of polemonia. The root of plantago is chewed for a similar purpose, or the teeth are rinsed with a decoction of the juice mixed with vinegar. The leaves, too, are said to be useful for the gums, when swollen with sanious blood, or if there are discharges of blood there-from. The seed, too, of plantago is a cure for abscesses in the gums, and for gum-boils. Aristolochia has a strengthening effect upon the gums and teeth; and the same with vervain, either chewed with the root of that plant, or boiled in wine and vinegar, the decoction being employed as a gargle. The same is the case, also, with root of cinquefoil, boiled down to one third, in wine or vinegar; before it is boiled, however, the root should be washed in sea or salt water: the decoction, too, must be kept a considerable time in the mouth. Some persons prefer cleaning the teeth with ashes of cinquefoil.

Root of verbascum is also boiled in wine, and the decoction used for rinsing the teeth. The same is done too with hyssop and juice of peucedanum, mixed with opium; or else the juice of the root of anagallis, the female plant in particular, is injected into the nostril on the opposite side to that in which the pain is felt.

Detailed table of contents

CHAP. 106.

ERIGERON, PAPPUS, ACANTHIS, OR SENECEO: EIGHT REMEDIES.

Erigeron is called by our people “senecio.” It is said that if a person, after tracing around this plant with an implement of iron, takes it up and touches the tooth affected with it three times, taking care to spit each time on the ground, and then replaces it in the same spot, so as to take root again, he will never experience any further pain in that tooth. This plant has just the appearance and softness of trixago, with a number of small reddish-coloured stems: it is found growing upon walls, and the tiled roofs of houses. The Greeks have given it the name of “erigeron,” because it is white in spring. The head is divided into numerous downy filaments, which resemble those of the thorn, protruding from between the divisions of the head: hence it is that Callimachus has given it the name of “acanthis,” while others, again, call it “pappus.”

After all, however, the Greek writers are by no means agreed as to this plant; some say, for instance, that it has leaves like those of rocket, while others maintain that they resemble those of the robur, only that they are considerably smaller. Some, again, assert that the root is useless, while others aver that it is beneficial for the sinews, and others that it produces suffocation, if taken in drink. On the other hand, some have prescribed it in wine, for jaundice and all affections of the bladder, heart, and liver, and give it as their opinion that it carries off gravel from the kidneys. It has been prescribed, also, by them for sciatica, the patient taking one drachma in oxymel, after a walk; and has been recommended as extremely useful for griping pains in the bowels, taken in raisin wine. They assert, also, that used as an aliment with vinegar, it is wholesome for the thoracic organs, and recommend it to be grown in the garden for these several purposes.

In addition to this, there are some authorities to be found, which distinguish another variety of this plant, but without mentioning its peculiar characteristics. This last they recommend to be taken in water, to neutralize the venom of serpents, and prescribe it to be eaten for the cure of epilepsy. For my own part, however, I shall only speak of it in accordance with the uses made of it among us Romans, uses based upon the results of actual experience. The down of this plant, beaten up with saffron and a little cold water, is applied to defluxions of the eyes; parched with a little salt, it is employed for the cure of scrofulous sores.

CHAP. 107.

THE EPHEMERON: TWO REMEDIES.

The ephemeron has leaves like those of the lily, but smaller; a stem of the same height, a blue flower, and a seed of which no use is made. The root is single, about the thickness of one's finger, and an excellent remedy for diseases of the teeth; for which purpose it is cut up in pieces, and boiled in vinegar, the decoction being used warm as a collutory. The root, too, is employed by itself to strengthen the teeth, being inserted for the purpose in those that are hollow or carious.

Root of chelidonia is also beaten up with vinegar, and kept in the mouth. Black hellebore is sometimes inserted in carious teeth; and a decoction of either of these last-mentioned plants, in vinegar, has the effect of strengthening loose teeth.

Detailed table of contents

CHAP. 108.

THE LABRUM VENEREUM : ONE REMEDY.

Labrum Venereum is the name given to a plant that grows in running streams. It produces a small worm, which is crushed by being rubbed upon the teeth, or else enclosed in wax and inserted in the hollow of the tooth. Care must be taken, however, that the plant, when pulled up, does not touch the ground.

Detailed table of contents

CHAP. 109.

THE BATRACHION, RANUNCULUS, OR STRUMUS ; FOUR VARIETIES OF IT: FOURTEEN REMEDIES.

The plant known to the Greeks as “batrachion,” we call ranunculus. There are four varieties of it, one of which has leaves somewhat thicker than those of coriander, nearly the size of those of the mallow, and of a livid hue: the stem of the plant is long and slender, and the root white; it grows on moist and well-shaded embankments. The second kind is more foliated than the preceding one, the leaves have more numerous incisions, and the stems of the plant are long. The third variety is smaller than the others, has a powerful smell, and a flower of a golden colour. The fourth kind is very like the one last mentioned, but the flower is milk-white.

All these plants have caustic properties: if the leaves are applied unboiled, they raise blisters like those caused by the action of fire; hence it is that they are used for the removal of leprous spots, itch-scabs, and brand marks upon the skin. They form an ingredient also in all caustic preparations, and are applied for the cure of alopecia, care being taken to remove them very speedily. The root, if chewed for some time, in cases of tooth-ache, will cause the teeth to break; dried and pulverized, it acts as a sternutatory.

Our herbalists give this plant the name of “strumus,” from the circumstance of its being curative of strumous sores and inflamed tumours, for which purpose a portion of it is hung up in the smoke. It is a general belief, too, with them, that if it is replanted, the malady so cured will reappear — a criminal practice, for which the plantago is also employed. The juice of this last-mentioned plant is curative of internal ulcerations of the mouth; and the leaves and root are chewed for a similar purpose, even when the mouth is suffering from defluxions. Cinquefoil effects the cure of ulcerations and offensive breath; psyllium is used also for ulcers of the mouth.

Detailed table of contents

CHAP. 110.

REMEDIAL PREPARATIONS FOR OFFENSIVE BREATH : TWO KINDS OF THEM.

We shall also here make mention of certain preparations for the cure of offensive breath — a most noisome inconvenience. For this purpose, leaves of myrtle and lentisk are taken in equal proportions, with one half the quantity of Syrian nut-galls; they are then pounded together and sprinkled with old wine, and the composition is chewed in the morning. In similar cases, also, ivy berries are used, in combination with cassia and myrrh; these ingredients being mixed, in equal proportions, with wine.

For offensive odours of the nostrils, even though attended with carcinoma, the most effectual remedy is seed of dracontium beaten up with honey. An application of hyssop has the effect of making bruises disappear. Brand marks in the face are healed by rubbing them with mandragora.

SUMMARY. — Remedies, narratives, and observations, twelve hundred and ninety-two.

ROMAN AUTHORS QUOTED. — C. Valgius, Pompeius Lennæus, Sextius Niger who wrote in Greek, Julius Bassus who wrote in Greek, Antonius Castor, Cornelius Celsus, Fabianus

FOREIGN AUTHORS QUOTED. — Theophrastus, Apollodorus, Peniocritus, Juba, Orpheus, Pythagoras, Mago, Menander who wrote the “Biochresta,” Nicander, Homer, Hesiod, Musæus, Sophocles, Xanthus, Anaxilaüs.

MEDICAL AUTHORS QUOTED. — Mnesitheus, Callimachus, Phantias the physician, Timaristus, Simus, Hippocrates, Chrysippus, Diocles, Ophelion, Heraclides, Hicesius, Dionysius, Apollodorus of Citium, Apollodorus of Tarentum, Praxagoras, Plistonicus, Medius, Dieuches, Cleophantus, Philistion, Asclepiades, Crateuas, Petronius Diodotus, Iollas, Erasistratus, Diagoras, Andreas, Mnesides, Epicharmus, Damion, Sosimenes, Tlepolemus, Metrodorus, Solon, Lycus, Olympias of Thebes, Philinus, Petrichus, Micton, Glaucias, Xenocrates.

**BOOK XXVI. A CONTINUATION OF THE
REMEDIES DERIVED FROM PLANTS, CLASSIFIED
ACCORDING TO PARTICULAR DISEASES.**

Detailed table of contents

CHAP. 1. (1.)

NEW FORMS OF DISEASE.

THE face of man has recently been sensible of new forms of disease, unknown in ancient times, not only to Italy, but to almost the whole of Europe. Still, however, they have not as yet extended to the whole of Italy, nor have they made any very great inroads in Illyricum, Gaul, or Spain, or indeed any other parts, to so great an extent as in Rome and its environs. Though unattended with pain, and not dangerous to life, these diseases are of so loathsome a nature, that any form of death would be preferable to them.

[Detailed table of contents](#)

CHAP. 2.

THE NATURE OF LICHEN.

The most insupportable of all these diseases is the one which, after its Greek appellation, is known to us as “lichen.” In consequence, however, of its generally making its first appearance at the chin, the Latin’s, by way of joke, originally — so prone are mankind to make a jest of the misfortunes of others — gave it the name of “mentagra;” an appellation which has since become established in general use. In many cases, however, this disease spreads over the interior of the mouth, and takes possession of the whole face, with the sole exception of the eyes; after which, it passes downwards to the neck, breast, and hands, covering them with foul furfuraceous eruptions.

Detailed table of contents

CHAP. 3.

AT WHAT PERIOD LICHEN FIRST MADE ITS APPEARANCE IN ITALY.

This curse was unknown to the ancients, and in the times of our fathers even, having first entered Italy in the middle of the reign of the Emperor Tiberius Claudius Cæsar; where it was introduced from Asia, in which country it had lately made its appearance, by a member of the equestrian order at Rome, a native of Perusiun, secretary to the quæstor. The disease, however, did not attack either females or slaves, nor yet the lower orders, or, indeed, the middle classes, but only the nobles, being communicated even by the momentary contact requisite for the act of salutation. Many of those who persevered in undergoing a course of remedial treatment, though cured of the disease, retained scars upon the body more hideous even than the malady itself; it being treated with cauteries, as it was certain to break out afresh, unless means were adopted for burning it out of the body by cauterizing to the very bone.

Upon this occasion several physicians repaired to Rome from Egypt, that fruitful parent of maladies of this nature, men who devoted themselves solely to this branch of medical practice; and very considerable were the profits they made. At all events, it is a well-known fact that Manilius Cornutus, a personage of prætorian rank, and legatus of the province of Aquitania, expended no less a sum than two hundred thousand sesterces upon his cure.

It is much more frequently, on the other hand, that we hear of new forms of diseases attacking the lower orders; a singular fact, and one quite unequalled for the marvellous phænomena which sometimes attend these outbreaks. Thus, for instance, we find an epidemic suddenly making its appearance in a certain country, and then confining itself, as though it had made its election so to do, to certain parts of the body, certain ages, and even certain pursuits in life. In the same way, too, while one class of diseases attacks the young, another confines itself to adults; while one malady extends itself only to the higher classes, another is felt exclusively by the poor.

[Detailed table of contents](#)

CHAP. 4.

CARBUNCLE.

We find it stated in the Annals, that it was in the censorship of L. Paulus and Q. Marcius that carbuncle was first introduced into Italy, a malady which till then had confined itself solely to the province of Gallia Narbonensis. In the year in which I am writing these lines, two persons of consular rank have died of this disease, Julius Rufus and Q. Lecanius Bassus; the former in consequence of an incision unskilfully made by his medical attendants, the latter through a wound upon the thumb of the left hand by pricking a carbuncle with a needle, a wound so small originally as to be hardly perceptible.

This disease makes its appearance in the more hidden parts of the human body, and mostly beneath the tongue. It originally has the form of a hard, red, pimple, with a blackish head mostly, though sometimes of a livid colour. It produces tension of the flesh, but unattended with swelling, pain, or any itching sensation; indeed, the only symptom that accompanies it is a confirmed drowsiness, which overpowers the patient, and carries him off in the course of three days. Sometimes, however, it is accompanied with shuddering, and small pustules about the sore; and occasionally, though but rarely, with fever. When these symptoms extend to the fauces and œsophagus, death ensues with the greatest rapidity.

[Detailed table of contents](#)

CHAP. 5

ELEPHANTIASIS.

We have already stated that elephantiasis was unknown in Italy before the time of Pompeius Magnus. This malady, too, like those already mentioned, mostly makes its first appearance in the face. In its primary form it bears a considerable resemblance to a small lentil upon the nose; the skin gradually dries up all over the body, is marked with spots of various colours, and presents an unequal surface, being thick in one place, thin in another, indurated every here and there, and covered with a sort of rough scab. At a later period, the skin assumes a black hue, and compresses the flesh upon the bones, the fingers and toes becoming swollen.

This disease was originally peculiar to Egypt. Whenever it attacked the kings of that country, it was attended with peculiarly fatal effects to the people, it being the practice to temper their sitting-baths with human blood, for the treatment of the disease. As for Italy, however, its career was very soon cut short: the same was the case, too, with the disease known as “gemursa” Fée thinks that this may have been a sort of abscess similar to those between the fingers which are known as *fourches* by the French, and by medical men as “Aposthema phalangum.” Gruner considers it to be a sort of Elephantiasis, and Triller identifies it with the disease called *Gumretha* by the Talmudists. to the ancients, a malady which made its appearance between the toes, and the very name of which is now buried in oblivion.

Detailed table of contents

CHAP. 6.

COLIC.

It is a remarkable fact that some diseases should disappear from among us, while others, again, should continue to prevail, colic for example. It was only in the reign of Tiberius Cæsar that this malady made its appearance in Italy, the emperor himself being the first to be attacked by it; a circumstance which produced considerable mystification throughout the City, when it read the edict issued by that prince excusing his inattention to public business, on the ground of his being laid up with a disease, the very name of which was till then unknown. To what cause are we to attribute these various diseases, or how is it that we have thus incurred the anger of the gods? Was it deemed too little for man to be exposed to fixed and determinate classes of maladies, already more than three hundred in number, that he must have new forms of disease to alarm him as well? And then, in addition to all these, not less in number are the troubles and misfortunes which man brings upon himself!

The remedies which I am here describing, are those which were universally employed in ancient times, Nature herself, so to say, making up the medicines: indeed, for a long time these were the only medicines employed.

(2.) Hippocrates, it is well known, was the first to compile a code of medical precepts, a thing which he did with the greatest perspicuity, as his treatises, we find, are replete with information upon the various plants. No less is the information which we gain from the works of Diocles of Carystus, second only in reputation, as well as date, to Hippocrates. The same, too, with reference to the works of Praxagoras, Chrysippus, and, at a later period, Erasistratus of Cos. Herophilus too, though himself the founder of a more refined system of medicine, was extremely profuse of his commendations of the use of simples. At a later period, however, experience, our most efficient instructor in all things, medicine in particular, gradually began to be lost sight of in mere words and verbiage: it being found, in fact, much more agreeable to sit in schools, and to listen to the talk of a professor, than to go a simpling in the deserts, and to be searching for this plant or that at all the various seasons of the year.

Detailed table of contents

CHAP. 7. (3.)

THE NEW SYSTEM OF MEDICINE: ASCLEPIADES THE PHYSICIAN.

Still, however, the ancient theories remained unshaken, based as they were upon the still existing grounds of universally acknowledged experience; until, in the time of Pompeius Magnus, Asclepiades, a professor of rhetoric, who considered himself not sufficiently repaid by that pursuit, and whose readiness and sagacity rendered him better adapted for any other than forensic practice, suddenly turned his attention to the medical art. Having never practised medicine, and being totally unacquainted with the nature of remedies — a knowledge only to be acquired by personal examination and actual experience — as a matter of course, he was obliged to renounce all previously-established theories, and to trust rather to his flowing periods and his well-studied discourses, for gaining an influence upon the minds of his audience.

Reducing the whole art of medicine to an estimation solely of primary causes, he made it nothing but a merely conjectural art, and established it as his creed, that there are five great principles of treatment for all diseases in common; diet, use or non-use of wine, frictions, exercise on foot, and exercise in a carriage or on horseback. As every one perceived that each of these methods of treatment lay quite within his own reach, all, of course, with the greatest readiness gave their assent, willing as they were to believe that to be true which was so easy of acquisition; and hence it was that he attracted nearly all the world about him, as though he had been sent among mankind on a special mission from heaven.

Detailed table of contents

CHAP. 8.

TIE CHANGES EFFECTED BY ASCLEPIADES IN THE PRACTICE OF MEDICINE.

In addition to this, he had a wonderful tact in gaining the full confidence of his patients: sometimes he would make then a promise of wine, and then seize the opportune moment for administering it, while on other occasions, again, he would prescribe cold water: indeed, as Herophilus, among the ancients, had been the first to enquire into the primary causes of disease, and Cleophantus had brought into notice the treatment of diseases by wine, so did Asclepiades, as we learn from M. Varro, prefer to be indebted for his surname and repute to the extensive use made by him of cold water as a remedy. He employed also various other soothing remedies for his patients; thus, for instance, it was he that introduced swinging beds, the motion of which might either lull the malady, or induce sleep, as deemed desirable. It was he, too, that brought baths into such general use, — a method of treatment that was adopted with the greatest avidity — in addition to numerous other modes of treatment of a pleasant and soothing nature. By these means he acquired a great professional reputation, and a no less extended fame; which was very considerably enhanced by the following incident: meeting the funeral procession of a person unknown to him, he ordered the body to be removed from the funeral pile and carried home, and was thus the means of saving his life. This circumstance I am the more desirous to mention, that it may not be imagined that it was on slight grounds only that so extensive a revolution was effected in the medical art.

There is, however, one thing, and one thing only, at which we have any ground for indignation,—the fact, that a single individual, and he belonging to the most frivolous nation in the world, a man born in utter indigence, should all on a sudden, and that, too, for the sole purpose of increasing his income, give a new code of medical laws to mankind; laws, however, be it remembered, which have been annulled by numerous authorities since his day. The success of Asclepiades was considerably promoted by many of the usages of ancient medicine, repulsive in their nature, and attended with far too much anxiety: thus, for instance, it was the practice to cover up the patient with vast numbers of clothes, and to adopt every possible method of promoting the perspiration; to order the body to be roasted before a fire; or else to be continually sending the patient on a search for sunshine, a thing hardly to be found in a showery climate like that of this city of ours; or rather, so to say, of the whole of Italy, so prolific as it is of fogs and rain. It was to remedy these inconveniences, that he introduced the use of hanging baths, an invention that was found grateful to invalids in the very highest degree.

In addition to this, he modified the tortures which had hitherto attended the treatment of certain maldies; as in quinzy for instance, the cure of which

before his time had been usually effected by the introduction of an instrument into the throat. He condemned, and with good reason, the indiscriminate use of emetics, which till then had been resorted to in; most extraordinary degree. He disapproved also of the practice of administering internally potions that are naturally injurious to the stomach, a thing that may truthfully be pronounced of the greater part of them. Indeed it will be as well to take an early opportunity of stating what are the medicaments which act beneficially upon the stomach.

Detailed table of contents

CHAP. 9. (4).

REMARKS IN DISPRAISE OF THE PRACTICES OF MAGIC.

But above all things, it was the follies of magic more particularly that contributed so essentially to his success — follies which had been carried to such a pitch as to destroy all confidence in the remedial virtues of plants. Thus, for instance, it was stoutly maintained that by the agency of the plant aethiopsis rivers and standing waters could be dried up, and that by the very touch * * * * all bars and doors might be opened: that if the plant achænis were thrown into the ranks of the enemy it would be certain to create a panic and put them to flight: that latace was given by the Persian kings to their ambassadors, to ensure them an abundant supply of everything wherever they might happen to be: with numerous other reveries of a similar nature. Where, I should like to know, were all these plants, when the Cimbri and Teutones brought upon us the horrors of warfare with their terrific yells? or when Lucullus defeated, with a few legions, so many kings who ruled over the Magi? Why is it too that the Roman generals have always made it their first care in warfare to make provision for the victualling of their troops? And how was it that at Pharsalia the troops of Cæsar were suffering from famine, if an abundance of everything could have been ensured by the fortunate possession of a single plant? Would it not have been better too for Scipio Æmilianus to have opened the gates of Carthage by touching them with a herb, than to have taken so many years to batter down its bulwarks with his engines of war?

Turning to the present moment, let them, by the agency of the herb meroïs, dry up the Pomptine Marshes, if they can, and by these means restore so much territory to the regions of Italy in the neighbourhood of our city. In the works, too, of Democritus, already mentioned, we find a recipe for the composition of a medicament which will ensure the procreation of issue, both sure to be good and fortunate. — What king of Persia, pray, ever obtained that blessing? It really would be a marvellous fact that human credulity, taking its rise originally in the very soundest of notions, should have ultimately arrived at such a pitch as this, if the mind of man understood, under any circumstances, how to keep within the bounds of moderation; and if the very system of medicine thus introduced by Asclepiades, had not been carried to a greater pitch of extravagance than the follies of magic even, an assertion which I shall prove on a more appropriate occasion.

Such, however, is the natural constitution of the human mind, that, be the circumstances what they may, commencing with what is necessary it speedily arrives at the point of launching out in excess.

We will now resume our account of the medicinal properties of the plants mentioned in the preceding Book, adding to our description such others as the necessities of the case may seem to require.

Detailed table of contents

CHAP. 10.

LICHEN: FIVE REMEDIES.

As to the treatment of lichen, so noisome a disease as it is, we shall here give a number of additional remedies for it, gathered from all quarters, although those already described are by no means few in number. For the cure of lichen plantago is used, pounded, cinquefoil also, root of albus in combination with vinegar, the young shoots of the fig-tree boiled in vinegar, or roots of marsh-mallow boiled down to one-fourth with glue and vinegar. The sores are rubbed also with pumice, and then fomented with root of rumex bruised in vinegar, or with scum of viscus kneaded up with lime. A decoction, too, of tithymalos with resin is highly esteemed for the same purpose.

But to all these remedies the plant known as “lichen,” from its efficacy as a cure, is held in preference. It is found growing among rocks, and has a single broad leaf near the root. and a single long stem, with small leaves hanging from it. This plant has the property also of effacing brand marks, being beaten up with honey for that purpose. There is another kind of lichen also, which adheres entirely to rocks, like moss, and which is equally used as a topical application. The juice of it, dropt into wounds, or applied to abscesses, has the property of arresting hæmorrhage: mixed with honey, it is curative of jaundice, the face and tongue being rubbed with it. Under this mode of treatment, the patient is recommended to wash in salt water, to anoint himself with oil of almonds, and to abstain from garden vegetables. For the cure of lichen, root of thapsia is also used, bruised in honey.

Detailed table of contents

CHAP. 11.

QUINZY.

For the treatment of quinzy, we find argemonia recommended, in wine; a decoction of hyssop, boiled with figs, used as a gargle; peucedanum, with an equal proportion of sea-calf's rennet; proserpinaca, beaten up in the pickle of the mæna and oil, or else placed beneath the tongue; as also juice of cinquefoil, taken in doses of three cyathi. Used as a gargle, juice of cinquefoil is good for the cure of all affections of the fauces: verbascum, too, taken in wine, is particularly useful for diseases of the tonsillary glands.

Detailed table of contents

CHAP. 12. (5.)

SCROFULA.

For the cure of scrofula plantago is employed, chelidonia mixed with honey and axle-grease, cinquefoil, and root of per- solata — this last being applied topically, and covered with the leaf of the plant — artemisia, also, and an infusion of the root of mandragora in water. The large-leaved sideritis, cleft by the left hand with a nail, is worn attached as an amulet: but after the cure has been effected, due care must be taken to preserve the plant, in order that it may not be set again, to promote the wicked designs of the herbalists and so cause the disease to break out afresh; as sometimes happens in the cases already mentioned, and others which I find stated, in reference to persons cured by the agency of artemisia or plantago.

Damasonion, also known as alcea, is gathered at the summer solstice, and applied with rain-water, the leaves being beaten up, or the root pounded, with axle-grease, so as to admit, when applied, of being covered with a leaf of the plant. The same plan is adopted also for the cure of all pains in the neck, and tumours on all parts of the body.

Detailed table of contents

CHAP. 13.

THE PLANT CALLED BELLIS: TWO REMEDIES.

Bellis is the name of a plant that grows in the fields, with a white flower somewhat inclining to red; if this is applied with artemisia, it is said, the remedy is still more efficacious.

[Detailed table of contents](#)

CHAP. 14.

THE CONDURDUM.

The condurdum, too, is a plant with a red blossom, which flowers at the summer solstice. Suspended from the neck, it arrests scrofula, they say: the same being the case also with vervain, in combination with plantago. For the cure of all diseases of the fingers, hangnails in particular, cinquefoil is used.

[Detailed table of contents](#)

CHAP. 15.

COUGH.

Of all diseases of the chest, cough is the one that is the most oppressive. For the cure of this malady, root of panaces in sweet wine is used, and in cases where it is attended with spitting of blood, juice of henbane. Henbane, too, used as a fumigation, is good for cough; and the same with scordotis, mixed with nasturtium and dry resin, beaten up with honey: employed by itself also, scordotis facilitates expectoration, a property which is equally possessed by the greater centaury, even where the patient is troubled with spitting of blood; for which last juice of plantago is very beneficial. Betony, taken in doses of three oboli in water, is useful for purulent or bloody expectorations: root also of persolata, in doses of one drachma, taken with eleven pine-nuts; and juice of peu- cedanum.

For pains in the chest, acoron is remarkably useful; hence it is that it is so much used an ingredient in antidotes. For cough, daucus and the plant scythice are much employed, this last being good, in fact, for all affections of the chest, coughs, and purulent expectorations, taken in doses of three oboli, with the same proportion of raisin wine. The verbascum too, with a flower like gold, is similarly employed.

(6.) This last-named plant is so remarkably energetic, that an infusion of it, administered in their drink, will relieve beasts of burden, not only when troubled with cough, but when broken-winded even — a property which I find attributed to gentian also. Root of cacalia chewed, or steeped in wine, is good for cough as well as all affections of the throat. Five sprigs of hyssop, with two of rue and three figs, act detergently upon the thoracic organs and allay cough,

[Detailed table of contents](#)

CHAP. 16.

BECHION, OTHERWISE KNOWN AS ARCION, CHAMÆ LEUCE OR TUSSILAGO:
THREE REMEDIES.

Bechion is known also as tussilago: there are two kinds of it. Wherever it is found growing wild, it is generally thought that there is a spring of water below, and it is looked upon as a sure sign that such is the case, by persons in search of water. The leaves are somewhat larger than those of ivy, and are some five or seven in number, of a whitish hue beneath, and a pale green on the upper surface, The plant is destitute of stem, blossom, and seed, and the root is very diminutive. Some persons are of opinion that this bechion is identical with the arcion, known also as the “chamæleuce.” The smoke of this plant in a dry state, inhaled by the aid of a reed and swallowed, is curative, they say, of chronic cough; it is necessary, however, at each inhalation to take a draught of raisin wine.

Detailed table of contents

CHAP. 17.

THE BECHION, KNOWN ALSO AS SALVIA: FOUR REMEDIES.

There is another bechion also, known to some persons as “salvia,” and bearing a strong resemblance to verbascum. This plant is triturated, and the juice strained off and taken warm for cough and for pains in the side: it is considered very beneficial also for the stings of scorpions and sea- dragons. It is a good plan, too, to rub the body with this juice, mixed with oil, as a preservative against the stings of serpents. A bunch of hyssop is sometimes boiled down with a quarter of a pound of honey, for the cure of cough.

[Detailed table of contents](#)

CHAP. 18. (7.)

AFFECTIONS OF THE SIDE, CHEST, AND STOMACH.

For the cure of pains in the side and chest, verbascum is used in water, with rue; powdered betony is also taken in warm water. Juice of scordotis is used as a stomachic, centaury also, gentian taken in water, and plantago, either eaten with the food, or mixed with lentils or a pottage of alica. Betony, which is in general prejudicial to the stomach, is remedial for some stomachic affections, taken in drink or chewed, the leaves being used for the purpose. In a similar manner too, aristolochia is taken in drink, or dried agaric is chewed, a draught of undiluted wine being taken every now and then. Nymphæa heraclia is also applied topically in these cases, and juice of peucedanum. For burning pains in the stomach psyllion is applied, or else cotyledon beaten up with polenta, or aizoüm.

Detailed table of contents

CHAP. 19.

MOLON OR SYRON. AMOMUM.

Molon is a plant with a striated stem, a soft diminutive leaf, and a root four fingers in length, at the extremity of which there is a head like that of garlic; by some persons it is known as “syron.” Taken in wine, it is curative of affections of the stomach, and of hardness of breathing. For similar purposes the greater centaury is used, in an electuary; juice also of plantago, or else the plant itself, eaten with the food; pounded betony, in the proportion of one pound to half an ounce of Attic honey, taken daily in warm water; and aristolochia or agaric, taken in doses of three oboli, in warm water or asses’ milk.

For hardness of breathing an infusion of cissanthemos is taken in drink, and for the same complaint, as also for asthma, hyssop. For pains in the liver, chest, and side, if unattended with fever, juice of peucedanum is used. For spitting of blood agaric is employed, in doses of one victoriatum, bruised and administered in five cyathi of honied. wine: amomum, too, is equally useful for that purpose. For liver diseases in particular, teucra is taken fresh, in doses of four drachme to one hemina of oxycrate; or else betony, in the proportion of one drachma to three cyathi of warm water. For diseases of the heart, betony is recommended, in doses of one drachma to two cyathi of cold water. Juice of cinquefoil is remedial for diseases of the liver and lungs, and for spitting of blood as well as all internal affections of the blood. The two varieties of anagallis are wonderfully efficacious for liver complaints. Patients who eat the plant called “capnos” discharge the bile by urine. Acoron is also remedial for diseases of the liver, and daucus is useful for the thorax and the pectoral organs.

[Detailed table of contents](#)

CHAP. 20

THE EPHEDRA OR ANABASIS; THREE REMEDIES.

The ephedra, by some persons called “anabasis,” mostly grows in localities exposed to the wind. It climbs the trunks of trees, and hangs down from the branches, is destitute of leaves, but has numerous suckers, jointed like a bulrush; the root is of a pale colour. This plant is given, pounded, in astringent red wine, for cough, asthma, and gripings in the bowels. It is administered also in the form of a pottage, to which some wine should be added. For these complaints, gentian is also used, being steeped in water the day before, and then pounded and given in doses of one denarius, in three cyathi of wine.

[Detailed table of contents](#)

CHAP. 21.

GEUM: THREE REMEDIES.

Geum is a plant with thin, diminutive roots, black, and aromatic. It is curative not only of pains in the chest and sides, but is useful also for dispelling crudities, owing to its agreeable flavour. Vervain, too, is good for all affections of the viscera, and for diseases of the sides, lungs, liver, and thorax. But one invaluable remedy for diseases of the lungs, and for cases of incipient phthisis, is the root of consiligo, a plant only very recently discovered, as already mentioned. It is a most efficient remedy also for pulmonary diseases in swine and cattle, even though only passed through the ear of the animal. When used, it should be taken in water, and kept for a considerable time in the mouth, beneath the tongue. Whether the part of this plant which grows above ground is useful or not for any purpose, is at present unknown. Ilantago, eaten with the food, betony taken in drink, and agaric taken in the way prescribed for cough, are useful, all of them, for diseases of the kidneys.

Detailed table of contents

CHAP. 22.

TRIPOLIUM : THREE REMEDIES.

Tripolium is a plant found growing upon cliffs on the sea-shore against which the waves break, springing up, so to say, neither upon dry land nor in the sea. The leaves are like those of isatis, only thicker; the stem is a palm in height and divided at the extremity, and the root white, thick, and odoriferous, with a warm flavour; it is recommended for diseases of the liver, boiled with spelt. This plant is thought by some to be identical with polium, of which we have already spoken in the appropriate place.

[Detailed table of contents](#)

CHAP. 23.

THE GROMPHÆNA.

Gromphæna is the name of a plant, the stem of which is covered with leaves of a green and rose colour, arranged alternately. The leaves of it are administered in oxycrate, in cases of spitting of blood.

[Detailed table of contents](#)

CHAP. 24.

THE MALUNDRUM : TWO REMEDIES.

For diseases of the liver the malundrum is prescribed, a plant which grows in meadows and corn-fields, with a white odoriferous flower. The stem is diminutive, and is beaten up in old wine.

Detailed table of contents

CHAP. 25.

CHALCETUM; TWO REMEDIES. MOLEMONIUM; ONE REMEDY.

Chalcetum also is the name of a plant, which is pounded with grape husks and applied topically, for the cure of liver complaints. Root of betony acts as a gentle emetic, taken in the same way as hellebore, in doses of four drachmæ in raisin wine or honied wine. Hyssop, too, is beaten up with honey for similar purposes; but it is more efficacious if nasturtium or irio is taken first.

Molemonium is used as an emetic, being taken in doses of one denarius; the same, too, with sillybum. Both of these plants have a milky juice, which thickens like gum, and is taken with honey in the proportions above-mentioned, being particularly good for carrying off bile. On the other hand, vomiting is arrested by the use of wild cummin or powdered betony, taken in water. Crudities and distaste for food are dispelled, and the digestion promoted by employing daucus, powdered betony taken in hydromel, or else plantago boiled like greens. Hiccup is arrested by taking hemionium or aristolochia, and asthma by the use of clymenus. For pleurisy and peripneumony, the greater centaury is used, or else hyssop, taken in drink. Juice of peucedanum is also good for pleurisy.

Detailed table of contents

CHAP. 26.

HALUS OR COTONEA: FIVE REMEDIES,

The plant halus, by the people of Gaul called “sil,” and by the Veneti “cotonea,” is curative of pains in the side, affections of the kidneys, ruptures, and convulsions. It resembles cunila bubula in appearance, and the tops of it are like those of thyme. It is of a sweet flavour, and allays thirst; the roots of it are sometimes white, sometimes black.

[Detailed table of contents](#)

CHAP. 27.

THE CHAMSHOPS: ONE REMEDY. THE STÆCHAS: ONE REMEDY.

The chamærops, also, is similarly efficacious for pains in the side. It is a plant with leaves like those of myrtle, arranged in pairs around the stem, the heads of it resembling those of the Greek rose: it is taken in wine. Agaric, administered in drink, in the same manner as for cough, assuages sciatica and pains in the vertebræ: the same, too, with powdered stæchas or betony, taken in hydromel.

Detailed table of contents

CHAP. 28. (8.)

REMEDIES FOR DISEASES OF THE BELLY.

But it is the belly, for the gratification of which the greater part of mankind exist, that causes the most suffering to man. Thus, for instance, at one time it will not allow the aliments to pass, while at another it is unable to retain them. Sometimes, again, it either cannot receive the food, or, if it can, cannot digest it; indeed, such are the excesses practised at the present day, that it is through his aliment, more than anything else, that man hastens his end. This receptacle, more troublesome to us than any other part of the body, is ever craving, like some importunate creditor, and makes its calls repeatedly in the day. It is for its sake, more particularly, that avarice is so insatiate, for its sake that luxury is so refined, for its sake that men voyage to the shores even of the Phasis, for its sake that the very depths of the ocean are ransacked. And yet, with all this, no one ever gives a thought how abject is the condition of this part of our body, how disgusting the results of its action upon what it has received! No wonder then, that the belly should have to be indebted to the aid of medicine in the very highest degree

Scordotis, fresh-gathered and beaten up, in doses of one drachma, with wine, arrests flux of the bowels; an effect equally produced by a decoction of it taken in drink. Polemonia, too, is given in wine for dysentery, or two fingers' length of root of verbascum, in water; seed of nymphaea heraclia, in wine; the upper root of xiphion, in (loses of one drachma, in vinegar; seed of plantago, beaten up in wine ; plantago itself boiled in vinegar, or else a pottage of alica mixed with the juice of the plant; plantago boiled with lentils ; plantago dried and powdered, and sprinkled in drink, with parched poppies pounded; juice of plantago, used as an injection, or taken in drink ; or betony taken in wine heated with a red-hot iron. For coeliac affections, betony is taken in astringent wine, or iberis is applied topically, as already stated. For tenesmus, root of nymphaea heraclia is taken in wine, or else psyllion in water, or a decoction of root of acoron. Juice of aizöum arrests diarrhoea and dysentery, and expels round tape-worm. Root of symphytum, taken in wine, arrests diarrhoea and dysentery, and daucus has a similar effect. Leaves of aizöum beaten up in wine, and dried alcea powdered and taken in wine, are curative of gripping pains in the bowels.

Detailed table of contents

CHAP. 29.

THE ASTRAGALUS: SIX REMEDIES.

Astragalus is the name of a plant which has long leaves. with numerous incisions, and running aslant near the root. The stems are three or four in number, and covered with leaves: the flower is like that of the hyacinth, and the roots are red, hairy, matted, and remarkably hard. It grows on stony localities, equally exposed to the sun and to falls of snow, those in the vicinity of Pheneus in Arcadia, for instance. Its properties are highly astringent; the root of it, taken in wine, arrests looseness of the bowels, having the additional effect of throwing downward the aqueous humours, and so acting as a diuretic; a property, in fact, which belongs to most substances which act astringently upon the bowels.

Bruised in red wine, this plant is curative of dysentery; it is only bruised, however, with the greatest difficulty. It is extremely useful, also, as a fomentation for gum-boils. The end of autumn is the time for gathering it, after the leaves are off; it being then. left to dry in the shade.

[Detailed table of contents](#)

CHAP. 30.

LADANUM: EIGHTEEN REMEDIES

Diarrhœa may be also arrested by the use of either kind of ladanum. The kind which is found in corn-fields is pounded for this purpose, and then passed through a sieve, being taken either in hydromel, or in wine of the highest quality. “Ledon” is the name of the plant from which ladanum is obtained in Cyprus, it being found adhering to the beard of the goats there; the most esteemed, however, is that of Arabia. At the present day, it is prepared in Syria and Africa also, being known as “toxicum,” from the circumstance that in gathering it, they pass over the plant a bow, with the string stretched, and covered with wool, to which the dewlike flocks of ladanum adhere. We have described it at further length, when treating of the perfumes.

This substance has a very powerful odour, and is hard in the extreme; for, in fact, there is a considerable quantity of earth adhering to it: it is most esteemed when in a pure state, aromatic, soft, green, and resinous. It is of an emollient, desiccative, and ripening nature, and acts as a narcotic: it prevents the hair from falling off, and preserves its dark colour. In combination with hydromel or oil of roses, it is used as an injection for the ears; with the addition of salt, it is employed for the cure of furfuraceous eruptions of the skin, and for running ulcers. Taken with storax, it is good for chronic cough; it is also extremely efficacious as a carminative.

Detailed table of contents

CHAP. 31.

CHONDRIS OR PSEUDODICTAMNON; ONE REMEDY. HYPO- CISTHIS OR OROBETHRON; TWO VARIETIES: EIGHT REMEDIES.

Chondris, too, or pseudodictamnon, acts astringently on the bowels. Hypocisthis, by some known also as “orobethron,” is similar to an unripe pomegranate in appearance; it grows, as already stated, beneath the cistus, whence its name. Dried in the shade, and taken in astringent, red wine, these plants arrest diarrhœa — for there are two kinds of hypocisthis, it must be remembered, the white and the red. It is the juice of the plant that is used, being of an astringent, desiccative, nature: that of the red kind, however, is the best for fluxes of the stomach. Taken in drink, in doses of three oboli, with amyllum, it arrests spitting of blood; and, employed either as a potion or as an injection, it is useful for dysentery. Vervain, too, is good for similar complaints, either taken in water, or, when there are no symptoms of fever, in Aminean wine, the proportion being five spoonfuls to three cyathi of wine.

Detailed table of contents

CHAP. 32.

LAVER OR SION: TWO REMEDIES.

Laver, too, a plant which grows in streams, preserved and boiled, is curative of griping pains in the bowels.

[Detailed table of contents](#)

CHAP. 33.

POTAMOGETON: EIGHT REMEDIES. THE STATICE: THREE REMEDIES.

Potamogeton, too, taken in wine, is useful for dysentery and coeliac affections: it is a plant similar to beet in the leaves, but smaller and more hairy, and rising but little above the surface of the water. It is the leaves that are used, being of a refreshing, astringent nature, and particularly good for diseases of the legs, and, with honey or vinegar, for corrosive ulcers.

Castor has given a different description of this plant. According to him, it has a smaller leaf, like horse-hair, with a long, smooth, stem, and grows in watery localities. With the root of it he used to treat scrofulous sores and indurations. Potamogeton neutralizes the effects of the bite of the crocodile; hence it is that those who go in pursuit of that animal, are in the habit of carrying it about them.

Achillea also arrests looseness of the bowels; an effect equally produced by the statice, a plant with seven heads, like those of the rose, upon as many stems.

[Detailed table of contents](#)

CHAP. 34.

THE CERATIA: TWO REMEDIES. LEONTOPODION, LEU- CEORON, DORIPETRON,
OR THORYBETHRON. LAGOPUS: THREE REMEDIES.

The ceratia is a plant with a single leaf, and a large knotted root: taken with the food, it is curative of cœliac affections and dysentery.

Leontopodion, a plant known also as “leuceoron,” “doripetron,” or “thorybethron,” has a root which acts astringently upon the bowels and carries off bile, being taken in doses of two denarii in hydromel. It grows in champaign localities with a poor soil: the seed, taken in drink, produces nightmare, it is said, in the sleep.

Lagopus arrests diarrhœa, taken in wine, or, if there are symptoms of fever, in water. This plant is attached to the groin, for tumours in that part of the body: it grows in cornfields. Many persons recommend, in preference to anything else, for desperate cases of dysentery, a decoction of roots of cinquefoil in milk, or else aristolochia, in the proportion of one victoriatum to three cyathi of wine. In the case of the preparations above-mentioned, which are recommended to be taken warm, it will be the best plan to heat them with a red-hot iron.

On the other hand, again, the juice of the smaller centaury acts as a purgative upon the bowels, and carries off bile, taken, in doses of one drachma, in one hemina of water with a little salt and vinegar. The greater centaury is curative of griping pains in the bowels. Betony, also, has a laxative effect, taken in the proportion of four drachmæ to nine cyathi of hydromel: the same, too, with euphorbia or agaric, taken, in doses of two drachmæ, with a little salt, in water, or else in three oboli of honied wine. Cyclaminos, also, is a purgative, either taken in water or used as a suppository; the same, too, with chamæ- cissos, employed as a suppository. A handful of hyssop, boiled down to one third with salt, or beaten up with oxymel and salt, and applied to the abdomen, promotes pituitous evacuations, and expels intestinal worms. Root also of peu- cedanum carries off pituitous humours and bile.

Detailed table of contents

CHAP. 35.

EPITHYMON OR HIPPOPHEOS: EIGHT REMEDIES.

The two kinds of anagallis, taken in hydromel, are purgative; the same, too, with epithymon, which is the blossom of a sort of thyme similar to savory; the only difference being that the flower of this plant is nearer grass green, while that of the other thyme is white. Some persons call it “hippopheos.” This plant is by no means wholesome to the stomach, as it is apt to cause vomiting, but at the same time it disperses flatulency and gripings of the bowels. It is taken also, in the form of an electuary, for affections of the chest, with honey, or in some cases, with iris. Taken in doses of from four to six drachmæ, with honey and a little salt and vinegar, it relaxes the bowels.

Some persons, again, give a different description of epithymon: according to them, it is a plant without a root, diminutive, and bearing a flower resembling a small hood, and of a red colour. They tell us, too, that it is dried in the shade and taken in water, in doses of half an acetabulum; and that it has a slightly laxative effect upon the bowels, and carries off the pituitous humours and bile. Nymphæa is taken for similar purposes, in astringent wine.

[Detailed table of contents](#)

CHAP. 36.

PYCNOCOMON; FOUR REMEDIES.

Pycnocomon, too, is a purgative. It is a plant with leaves like those of rocket, only thicker and more acrid; the root is round, of a yellow colour, and with an earthy smell. The stem is quadrangular, of a moderate length, thin, and surmounted with a flower like that of ocimum. It is found growing in rough stony soils. The root, taken in doses of two denarii in hydromel, acts as a purgative upon the bowels, and effectually carries off bile and pituitous humours. The seed, taken in doses of one drachma in wine, is productive of dreams and restlessness. Capnos, too, carries off bile by the urine.

[Detailed table of contents](#)

CHAP. 37.

POLYPODION: THREE REMEDIES.

Polypodium, known to us by the name of “flicula,” bears some resemblance to fern. The root of it is used medicinally; being fibrous, and of a grass green colour within, about the thickness of the little finger, and covered with cavernous suckers like those on the arms of the polypus. This plant is of a sweetish taste, and is found growing among rocks and under trees. The root is steeped in water, and the juice extracted; sometimes, too, it is cut in small pieces and sprinkled upon cabbage, beet, mallows, or salt meat; or else it is boiled with pap, as a gentle aperient for the bowels, in cases of fever even. It carries off bile also and the pituitous humours, but acts injuriously upon the stomach. Dried and powdered and applied to the nostrils, it cauterizes polypus of the nose. It has neither seed nor flower.

Detailed table of contents

CHAP. 38.

SCAMMONY; EIGHT REMEDIES.

Scammony, also, is productive of derangement of the stomach. It carries off bile, and acts strongly as a purgative upon the bowels; unless, indeed, aloes are added, in the proportion of two drachmæ of aloes to two oboli of scammony. The drug thus called is the juice of a plant that is branchy from the root, and has unctuous, white, triangular, leaves, with a solid, moist root, of a nauseous flavour: it grows in rich white soils. About the period of the rising of the Dogstar, an excavation is made about the root, to let the juice collect: which done. it is dried in the sun and divided into tablets. The root itself, too, or the outer coat of it, is sometimes dried. The scammony most esteemed is that of Colophon, Mysia, and Priene. In appearance it ought to be smooth and shiny, and as much like bull glue as possible: it should present a fungous surface also, covered with minute holes; should melt with the greatest rapidity, have a powerful smell, and be sticky like gum. When touched with the tongue, it should give out a white milky liquid; it ought also to be extremely light, and to turn white when melted.

This last feature is recognized in the spurious scammony also, a compound of meal of fitches and juice of marine tithy- malos, which is mostly imported from Judea, and is very apt to choke those who use it. The difference may be easily detected, however, by the taste, as tithymalos imparts a burning sensation to the tongue. To be fully efficacious, scammony should be two years old; before or after that age it is useless. It has been prescribed to be taken by itself also, in doses of four oboli, with hydromel and salt: but the most advantageous mode of using it is in combination with aloes, care being taken to drink honied wine the moment it begins to operate. The root, too, is boiled down in vinegar to the consistency of honey, and the decoction used as a liniment for leprosy. The head is also rubbed with this decoction, mixed with oil, for head-ache.

Detailed table of contents

CHAP. 39.

THE TITHYMALOS CHARACIAS.

The tithymalos is called by our people the “milk plant,” and by some persons the “goat lettuce.” They say, that if characters are traced upon the body with the milky juice of this plant, and powdered with ashes, when dry, the letters will be perfectly visible; an expedient which has been adopted before now by intriguers, for the purpose of communicating with their mistresses, in preference to a correspondence by letter. There are numerous varieties of this plant. The first kind has the additional name of “characias,” and is generally looked upon as the male plant. Its branches are about a finger in thickness, red and full of juice, five or six in number, and a cubit in length. The leaves near the root are almost exactly those of the olive, and the extremity of the stem is surmounted with a tuft like that of the bulrush: it is found growing in rugged localities near the sea-shore. The seed is gathered in autumn, together with the tufts, and after being dried in the sun, is beaten out and put by for keeping. As to the juice, the moment the down begins to appear upon the fruit, the branches are broken off and the juice of them is received upon either meal of fitches or else figs, and left to dry therewith. Five drops are as much as each fig ought to receive; and the story is, that if a dropsically patient eats one of these figs he will have as many motions as the fig has received drops. While the juice is being collected, due care must be taken not to let it touch the eyes. From the leaves, pounded, a juice is also extracted, but not of so useful a nature as the other kind: a decoction, too, is made from the branches.

The seed also is used, being boiled with honey and made up into purgative pills. These seeds are sometimes inserted in hollow teeth with wax: the teeth are rinsed too, with a decoction of the root in wine or oil. The juice is used externally for lichens, and is taken internally both as an emetic and to promote alpine evacuation: in other respects, it is prejudicial to the stomach. Taken in drink, with the addition of salt, it carries off pituitous humours; and in combination with saltpeter, removes bile. In cases where it is desirable that it should purge by stool, it is taken with oxycrate, but where it is wanted to act as an emetic, with raisin wine or hydromel; three oboli being a middling dose. The best method, however, of using it, is to eat the prepared figs above-mentioned, just after taking food. In taste, it is slightly burning to the throat; indeed it is of so heating a nature, that, applied externally by itself, it raises blisters on the flesh, like those caused by the action of fire. Hence it is that it is sometimes employed as a cautery.

CHAP. 40.

THE TITHYMALOS MYRTITES, OR CARYITES; TWENTY- ONE REMEDIES.

A second kind of tithymalos is called “myrtites” by some persons, and “caryites” by others. It has leaves like those of myrtle, pointed and prickly, but with a softer surface, and grows, like the one already mentioned, in rugged soils. The tufted heads of it are gathered just as barley is beginning to swell in the ear, and, after being left for nine days in the shade, are thoroughly dried in the sun. The fruit does not ripen all at once, some, indeed, not till the ensuing year. The name given to this fruit is the “nut,” whence the Greek appellation “caryites.” It is gathered at harvest, and is washed and dried, being given with twice the quantity of black poppy, in doses of one acetabulum in all.

As an emetic, this kind is not so efficacious as the preceding one, and, indeed, the same may be said of all the others. Some physicians recommend the leaf to be taken in the manner already mentioned, but say that the nut should either be taken in honied wine or raisin wine, or else with sesame. It carries off pituitous humours and bile by stool, and is curative of ulcerations of the mouth. For corrosive sores of the mouth, the leaf is eaten with honey.

Detailed table of contents

CHAP. 41.

THE TITHYMALOS PARALIOS, OR TITHYMALIS: FOUR REMEDIES.

A third kind of tithymalos is known by the additional name of “paralios,” or else as “tithymalis.” The leaf is round, the stem a palm in height, the branches red, and the seed white. This seed is gathered just as the grape is beginning to form, and is dried and pounded; being taken as a purgative, in doses of one acetabulum.

Detailed table of contents

CHAP. 42.

THE TITHYMALOS HELIOSCOPIOS : EIGHTEEN REMEDIES.

A fourth kind of tithymalos is known by the additional name of “helioscopios.” It has leaves like those of purslain, and some four or five small branches standing out from the root, of a red colour, half a foot in height, and full of juice. This plant grows in the vicinity of towns: the seed is white, and pigeons are remarkably fond of it. It receives its additional name of “helioscopios” from the fact that the heads of it turn with the sun. Taken in doses of half an acetabulum, in oxymel, it carries off bile by stool: in other respects it has the same properties as the characias, above-mentioned.

Detailed table of contents

CHAP. 43.

THE TITHYMALOS CYPARISSIAS : EIGHTEEN REMEDIES.

In the fifth place we have the tithymalos known as “cyparissias,” from the resemblance of its leaves to those of the cypress. It has a double or triple stem, and grows in champaign localities. Its properties are exactly similar to those of the helioscopios and characias.

Detailed table of contents

CHAP. 44.

THE TITHYMALOS PLATYPHYLLOS, CORYMBITES, OR AMYGDALITES: THREE
REMEDIES.

The sixth kind is called “platyphyllos” by some, and “corymbites” or “amygdalites” by others, from its resemblance to the almond-tree. The leaves of this kind are the largest of all: it has a fatal effect upon fish. An infusion of the root or leaves, or the juice, taken in doses of four drachmæ, in honied wine, or hydromel, acts as a purgative. It is particularly useful also for carrying off the aqueous humours.

Detailed table of contents

CHAP. 45.

THE TITHYMALOS DENDROÏDES, COBIOS, OR LEPTO- PHYLLOS: EIGHTEEN
REMEDIES.

The seventh kind has the additional name of “dendroïdes,” and is known by some persons as “cobios,” and by others as “leptophyllos.” It grows among rocks, and is by far the most shrubby of all the varieties of the tithymalos. The stems of it are small and red, and the seed is remarkably abundant. Its properties are the same as those of the characias.

Detailed table of contents

CHAP. 46.

THE APIOS ISCHAS, OR RAPHANOS AGRIA: TWO REMEDIES.

The apios ischas or raphanos agria, throws out two or three rush-like branches of a red colour, creeping upon the ground, and bearing leaves like those of rue. The root resembles that of an onion, only that it is larger, for which reason some have called it the “wild radish.” The interior of this root is composed of a mammosse substance, containing a white juice: the outer coat is black. It grows in rugged, mountainous spots, and sometimes in pasture lands. It is taken up in spring, and pounded and put into an earthen vessel, that portion of it being removed which floats upon the surface. The part which remains acts purgatively, taken in doses of an obolus and a half in hydromel, both as an emetic and by stool. This juice is administered also, in doses of one acetabulum, for dropsy.

The root of this plant is dried and powdered, and taken in drink: the upper part of it, they say, carries off bile by acting as an emetic, the lower part, by promoting alvine evacuation.

[Detailed table of contents](#)

CHAP. 47.

REMEDIES FOR GRIPING PAINS IN THE BOWELS.

Every kind of panaces is curative of gripings in the bowels; as also betony, except in those cases where they arise from indigestion. Juice of peucedanum is good for flatulency, acting powerfully as a carminative: the same is the case, also, with root of acoron and with daucus, eaten like lettuce as a salad. Ladanum of Cyprus, taken in drink, is curative of intestinal affections; and a similar effect is produced by powdered gentian, taken in warm water, in quantities about as large as a bean. For the same purpose, plantago is taken in the morning, in doses of two spoonfuls, with one spoonful of poppy in four cyathi of wine, due care being taken that it is not old wine. It is given, too, at the last moment before going to sleep, and with the addition of nitre or polenta, if a considerable time has elapsed since the last meal. For colic, an injection of the juice is used, one hemina at a time, even in cases where fever has supervened.

[Detailed table of contents](#)

CHAP. 48.

REMEDIES FOR DISEASES OF THE SPLEEN.

Agaric, taken in doses of three oboli in one cyathus of old wine, is curative of diseases of the spleen. The same, too, with the root of every kind of panaces, taken in honied wine: teucra, also, is particularly useful for the same purpose, taken in a dry state, or boiled down in the proportion of one handful to three heminae of vinegar. Teucra, too, is applied with vinegar to wounds of the spleen, or, if the patient cannot bear the application of vinegar, with figs or water. Polemonia is taken in wine, and betony, in doses of one drachma, in three cyathi of oxymel: aristolochia, too, is used in the same manner as for injuries inflicted by serpents. Argemonia, it is said, taken with the food for seven consecutive days, diminishes the volume of the spleen; and a similar effect is attributed to agaric, taken in doses of two oboli, in oxymel. Root, too, of nymphæa heraclia, taken in wine, or by itself, diminishes the spleen.

Cissanthemos, taken twice a day, in doses of one drachma in two cyathi of white wine, for forty consecutive days, gradually carries off the spleen, it is said, by urine. Hyssop, boiled with figs, is very useful for the same purpose: root of lonchitis, also, boiled before it has shed its seed. A decoction of root of peucedanum is good for the spleen and kidneys. Acoron, taken in drink, diminishes the spleen; and the roots of it are very beneficial for the viscera and iliac regions. For similar purposes, seed of clymenus is taken, for thirty consecutive days, in doses of one denarius, in white wine. Powdered betony is also used, taken in a potion with honey and squill vinegar; root too of lonchitis is taken in water. Tourism is used externally for diseases of the spleen; sodium, also, in combination with wax: and agaric, mixed with powdered fenugreek.

Detailed table of contents

CHAP. 49.

REMEDIES FOR CALCULI AND DISEASES OF THE BLADDER.

For diseases of the bladder and calculi (affections which, as already observed, produce the most excruciating torments), palmonies is highly efficacious, taken in wine; agaric also, and leaves or root of plantago, taken in raisin wine. Betony, too, is very good, as already observed, when speaking of diseases of the liver. This last plant is used also for hernia, applied topically or taken in drink: it is remarkably efficacious too for stranguer. For calculi some persons recommend betony, vervain, and milfoil, in equal proportions in water, as a sovereign remedy. It is universally agreed that dittany is curative of stranguer, and that the same is the case with ainquefoil, boiled down to one third in wine: this last plant is very useful, too, taken internally and applied topically, for rupture of the groin.

The upper part of the root of xiphion has a diuretic effect upon infants; it is administered also in water for rupture of the groin, and is applied topically for diseases of the bladder. Juice of peucedanum is employed for hernia in infants, and psyllion is used as an application in cases of umbilical hernia. The two kinds of anagallis are diuretic, and a similar effect is produced by a decoction of root of acoron, or the plant itself bruised and taken in drink; this last is good too for all affections of the bladder. Both the stem and root of cotyledon are used for the cure of calculi; and for all inflammations of the genitals, myrrh is mixed in equal proportions with the stem and seed. The more tender leaves of ebulum, beaten up and taken with wine, expel calculi of the bladder, and an application of them is curative of diseases of the testes. Erigeron, with powdered frankincense and sweet wine, is curative of inflammation of the testes; and root of symphytum, applied topically, reduces rupture of the groin. The white hypocisthis is curative of corroding ulcers of the genitals. Artemisia is prescribed also in sweet wine for the cure of calculi and of stranguer; and root of nymphæa heraclia, taken in wine, allays pains in the bladder.

Detailed table of contents

CHAP. 50.

CRETHMOS: ELEVEN REMEDIES. CACHRY.

A similar property belongs also to crethmos, a plant highly praised by Hippocrates. This is one of the wild plants that are commonly eaten — at all events, we find Callimachus mentioning it as one of the viands set on table by the peasant Hecale. It is a species of garden batis, with a stem a palm in height, and a hot seed, odoriferous like that of libanotis, and round. When dried, the seed bursts asunder, and discloses in the interior a white kernel, known as “cachry” to some. The leaf is unctuous and of a whitish colour, like that of the olive, only thicker and of a saltish taste. The roots are three or four in number, and about a finger in thickness: the plant grows in rocky localities, upon the sea-shore. It is eaten raw or else boiled with cabbage, and has a pleasant, aromatic flavour; it is preserved also in brine.

This plant is particularly useful for strangury, the leaves, stem, or root being taken in wine. It improves the complexion of the skin also, but if taken in excess is very apt to produce flatulency. Used in the form of a decoction it relaxes the bowels, has a diuretic effect, and carries off the humours from the kidneys. The same is the case also with alcea: dried and powdered and taken in wine, it removes strangury, and, with the addition of daucus, is still more efficacious: it is good too for the spleen, and is taken in drink as an antidote to the venom of serpents. Mixed with their barley it is remarkably beneficial for beasts of burden, when suffering from pituitous defluxions or strangury.

Detailed table of contents

CHAP. 51.

THE ANTHYLLION; TWO REMEDIES THE ANTHYLLIS: TWO REMEDIES.

The anthyllion is a plant very like the lentil. Taken in wine, it is remedial for diseases of the bladder, and arrests hæmorrhage. Another variety of it is the anthyllis, a plant resembling the chamæpitys, with a purple flower, a powerful smell, and a root like that of endive.

Detailed table of contents

CHAP. 52.

CEPÆA: ONE REMEDY.

The plant known as “cepæa” is even more efficacious. It resembles purslain in appearance, but has a darker root, that is never used: it grows upon the sands of the sea-shore, and has a bitter taste. Taken in wine with root of asparagus, it is remarkably useful for diseases of the bladder.

[Detailed table of contents](#)

CHAP. 53.

HYPERICON, CHAMÆPITYS, OR CORISON: NINE REMEDIES.

Hypericon, otherwise known as the “chamæpitys” or “orison,” is possessed of similar properties. It is a plant with a stem like that of a garden vegetable, thin, red, and a cubit in length. The leaf is similar to that of rue, and has an acrid smell: the seed is enclosed in a swarthy pod, and ripens at the same time as barley. This seed is of an astringent nature, arrests diarrhœa, and acts as a diuretic: it is taken also for diseases of the bladder, in wine.

[Detailed table of contents](#)

CHAP. 54.

CAROS OR HYPERICON: TEN REMEDIES.

There is another hypericon also, known as “caros” by some. The leaves of it resemble those of the tamarix, beneath which it grows, but are more unctuous and not so red. It is an odoriferous plant, somewhat more than a palm in height, of a sweet flavour, and slightly pungent. The seed is of a warming nature, and is consequently productive of eructations; it is not, however, injurious to the stomach. This plant is particularly useful for strangury, provided the bladder be not ulcerated; taken in wine, it is curative of pleurisy also.

[Detailed table of contents](#)

CHAP. 55.

THE CALLITHRIX: ONE REMEDY. THE PERPRESSA: ONE REMEDY. THE
CHRYSANTHEMUM: ONE REMEDY. THE ANTHEMIS: ONE REMEDY.

Callithrix, beaten up with cummin seed, and administered in white wine, is useful also for diseases of the bladder. Leaves of vervain, boiled down to one third, or root of vervain, in warm honied wine, expel calculi of the bladder.

Perpressa, a plant which grows in the vicinity of Arretium and in Illyricum, is boiled down to one third in three heminæ of water, and the decoction taken in drink: the same too with trefoil, which is administered in wine; and the same with the chrysanthemum. The anthemis also is an expellent of calculi. It is a plant with five small leaves running from the root, two long stems, and a flower like a rose. The roots of it are pounded and administered alone, in the same way as raw laver.

Detailed table of contents

CHAP. 56.

SILAUS: ONE REMEDY.

Silaus is a plant which grows in running streams with a gravelly bed. It bears some resemblance to parsley, and is a cubit in height. It is cooked in the same manner as the acid vegetables, and is of great utility for affections of the bladder. In cases where that organ is affected with eruptions, it is used in combination with root of panaces, a plant which is otherwise bad for the bladder.

The erratic apple, too, is an expellent of calculi. For this purpose, a pound of the root is boiled down to one half in a congius of wine, and one hemina of the decoction is taken for three consecutive days, the remainder being taken in wine with sium. Sea-nettle is employed too for the same purpose, daucus, and seed of plantago in wine.

[Detailed table of contents](#)

CHAP. 57.

THE PLANT OF FULVIUS.

The plant of Fulvius too — so called from the first discoverer of it, and well known to herbalists — bruised in wine, acts as a diuretic.

[Detailed table of contents](#)

CHAP. 58.

REMEDIES FOR DISEASES OF THE TESTES AND OF THE FUNDAMENT.

Scordion reduces swellings of the testes. Henbane is curative of diseases of the generative organs. Strangury is cured by juice of peucedanum, taken with honey; as also by the seed of that plant. Agaric is also used for the same purpose, taken in doses of three oboli in one cyathus of old wine; root of trefoil, in doses of two drachmæ in wine; and root or seed of daucus, in doses of one drachma. For the cure of sciatica, the seed and leaves of erythrodanum are used, pounded; panaces, taken in drink; polemonia, employed as a friction; and leaves of aristolochia, in the form of a decoction. Agaric, taken in doses of three oboli in one cyathus of old wine, is curative of affections of the tendon known as “platys” and of pains in the shoulders. Cinquefoil is either taken in drink or applied topically for the cure of sciatica; a decoction of scammony is used also, with barley meal; and the seed of either kind of hypericon is taken in wine.

For diseases of the fundament and for excoriations plantago is remarkably efficacious; for condylomata, cinquefoil; and for procidence of the rectum, root of cyclaminos, applied in vinegar. The blue anagallis reduces procidence of the rectum, while, on the contrary, that with a red flower has a tendency to bear it down. Cotyledons is a marvellous cure for condylomatous affections and piles; and root of acoron, boiled in wine and beaten up, is a good application for swelling of the testes. According to what Cato says, those who carry about them Pontic wormwood, will never experience chafing between the thighs.

(9.) Some persons add pennyroyal to the number of these plants: gathered fasting, they say, and attached to the hinder part of the body, it will be an effectual preservative against all pains in the groin, and will allay them in cases where they already exist.

Detailed table of contents

CHAP. 59.

INGUINALIS OR ARGEMO.

Inguinalis again, or, as some persons call it, “argemo,” a plant commonly found growing in bushes and thickets, needs only to be held in the hand to be productive of beneficial effects upon the groin.

Detailed table of contents

CHAP. 60.

REMEDIES FOR INFLAMED TUMOURS. CHRYSIPPIOS: ONE REMEDY.

Panaces, applied with honey, heals inflammatory tumours; an effect which is equally produced by plantago applied with salt, cinquefoil, root of persolata used in the same way as for scrofula; damasonium also, and verbascum pounded with the root, and then sprinkled with wine, and wrapped in a leaf warmed upon ashes, and applied hot. Persons of experience in these matters have asserted that it is of primary importance that the application should be made by a maiden, as also that she must be naked at the time, and fasting. The patient must be fasting too, and the damsel must say, touching him with the back of her hand, “Apollo forbids that a disease shall increase which a naked virgin restrains.” So saying, she must withdraw her hand, and repeat to the above effect three times, both of them spitting upon the ground each time.

Root, too, of mandragora is used for this purpose, with water; a decoction of root of scammony with honey; sideritis beaten up with stale grease; horehound with stale axlegrease; or chrysippios, a plant which owes its name to its discoverer — with pulpy figs.

Detailed table of contents

CHAP. 61. (10.)

APHRODISIACS AND ANT APHRODISIACS.

Nymphæa heraclia, used as already stated, acts most powerfully as an ant aphrodisiac; the same too if taken once every forty days in drink. Taken in drink fasting, or eaten with the food, it effectually prevents the recurrence of libidinous dreams. The root too, used in the form of a liniment and applied to the generative organs, not only represses all prurient desires, but arrests the seminal secretions as well; for which reason, it is said to have a tendency to make flesh and to improve the voice.

The upper part of the root of xiphion, taken in wine, acts as an aphrodisiac. The same is the case too with the wild crethmos, or agrees as it is called, and with holmium, beaten up with polenta.

Detailed table of contents

CHAP. 62.

THE ORCHIDS OR SERAPES: FIVE MEDICINAL PROPERTIES. SATYR ION.

But there are few plants of so marvellous a nature as the orchids or serapias, a vegetable production with leaves like those of the leek, a stem a palm in height, a purple flower, and a twofold root, formed of tuberosities which resemble the testes in appearance. The larger of these tuberosities, or, as some say, the harder of the two. taken in water, is provocative of lust; while the smaller, or, in other words, the softer one, taken in goat's milk, acts as an antaphrodisiac. Some persons describe this plant as having a leaf like that of the squill, only smoother and softer, and a prickly stem. The roots heal ulcerations of the mouth, and are curative of pituitous discharges from the chest; taken in wine they act astringently upon the bowels.

Satyrium is also a powerful stimulant. There are two kinds of it: the first has leaves like those of the olive, but longer, a stem four fingers in length, a purple flower, and a double root, resembling the human testes in shape. This root swells and increases in volume one year, and resumes its original size the next. The other kind is known as the "satyrios orchis," and is supposed to be the female plant. It is distinguished from the former one by the distance between its joints, and its more branchy and shrublike form. The root is employed in philtres: it is mostly found growing near the sea. Beaten up and applied with polenta, or by itself, it heals tumours and various other affections of the generative organs. The root of the first kind, administered in the milk of a colonic sheep, causes tentigo; taken in water it produces a contrary effect.

Detailed table of contents

CHAP. 63.

SATYRION: THREE MEDICINAL PROPERTIES. SATY- RION ERYTHRAÏCON: FOUR MEDICINAL PROPERTIES.

The Greeks give the name of “satyrion” to a plant with red leaves like those of the lily, but smaller, not more than three of them making their appearance above ground. The stem, they say, is smooth and bare and a cubit in length, and the root double; the lower part, which is also the larger, promoting the conception of male issue, the upper or smaller part, that of female.

They distinguish also another kind of satyrion, by the name of “erythraïcon” it has seed like that of the vitex, only larger, smooth, and hard; the root, they say, is covered with a red rind, and is white within and of a sweetish taste: it is mostly found in mountainous districts. The root, we are told, if only held in the hand, acts as a powerful aphrodisiac, and even more so, if it is taken in rough, astringent wine. It is administered in drink, they say, to rams and he-goats when inactive and sluggish; and the people of Sarmatia are in the habit of giving it to their stallions when fatigued with covering, a defect to which they give the name of “prosedamum.” The effects of this plant are neutralized by the use of hydromel or lettuces.

The Greeks, however, give the general name of “satyrion” to all substances of a stimulating tendency, to the cratægis for example, the thelygonon, and the arrenogonon, plants, the seed of which bears a resemblance to the testes. Persons who carry the pith of branches of tithymalos about them, are rendered more amorous thereby, it is said. The statements are really incredible, which Theophrastus, in most cases an author of high authority, makes in relation to this subject; thus, for instance, he says that by the contact only of a certain plant, a man has been enabled, in the sexual congress, to repeat his embraces as many as seventy times even! The name and genus, however, of this plant, he has omitted to mention.

Detailed table of contents

CHAP. 64.

REMEDIES FOR THE GOUT AND DISEASES OF THE FEET.

Sideritis, attached to the body as an amulet, reduces varicose veins, and effects a painless cure. Gout used to be an extremely rare disease, not in the times of our fathers and grandfathers only, but within my own memory even. Indeed, it may justly be considered a foreign complaint; for if it had been formerly known in Italy, it would surely have found a Latin name. It should, however, by no means be looked upon as an incurable malady; for before now, in many instances, it has quitted the patient all at once, and still more frequently, a cure has been effected by proper treatment.

For the cure of gout, roots of panaces are used, mixed with raisins; juice of henbane, or the seed, combined with meal; scordion, taken in vinegar; iberis, as already mentioned; vervain, beaten up with axle-grease or root of cyclaminos, a decoction of which is good also for chilblains.

As cooling applications for gout, root of xiphion is used; seed of psyllion; hemlock, with litharge or axle-grease; and, at the first symptoms of red gout, or, in other words, hot gout, the plant aizoüm. For either kind of gout, erigeron, with axle-grease, is very useful; leaves of plantago, beaten up with a little salt; or argemonia, pounded with honey. An. application of vervain is also remedial, and it is a good plan to soak the feet in a decoction of that plant in water.

Detailed table of contents

CHAP. 65.

LAPPAGO OR MOLLUGO: ONE REMEDY. ASPERUGO: ONE REMEDY.

Lappago is employed also for this disease; a plant similar to the anagallis, were it not that it is more branchy, bristling with a greater number of leaves, covered with rugosities, full of a more acrid juice, and possessed of a powerful smell. The kind that resembles anagallis most closely, is known as mollugo. Asperugo is a similar plant, only with a more prickly leaf. The juice of the first is taken daily, in doses of one denarius, in two cyathi of wine.

[Detailed table of contents](#)

CHAP. 66.

PHYCOS THALASSION OR SEA-WEED: THREE VARIETIES OF IT. LAPPA BOARIA.

But it is the phycos thalassion, or sea-weed, more particularly, that is so excellent a remedy for the gout. It resembles the lettuce in appearance, and is used as the basis in dyeing tissues with the purple of the murex. Used before it becomes dry, it is efficacious as a topical application not only for gout, but for all diseases of the joints. There are three kinds of it; one with a broad leaf, another with a longer leaf of a reddish hue, and a third with a crisped leaf, and used in Crete for dyeing cloths. All these kinds have similar properties; and we find Nicander prescribing them in wine as an antidote to the venom of serpents even. The seed also of the plant which we have spoken of as “psyllion,” is useful for the cure of gout: it is first steeped in water, and one hemina of the seed is then mixed with two spoonfuls of resin of Colophon, and one spoonful of frankincense. Leaves of mandragora, too, are highly esteemed for this purpose, beaten up with polenta.

(11.) For swellings of the ankles, slime, kneaded up with oil, is wonderfully useful, and for swellings of the joints the juice of the smaller centaury; this last being remarkably good also for diseases of the sinews. Centauris, too, is very useful; and for pains in the sinews of the shoulder-blades, shoulders, vertebræ, and loins, an infusion of betony is taken in drink in the same way as for diseases of the liver. Cinquefoil is applied topically to the joints, and a similar use is made of the leaves of mandragora, mixed with polenta, or else the root, beaten up fresh with wild cucumber or boiled in water. For chaps upon the toes, root of polypodion is used; and for diseases of the joints, juice of henbane with axle-grease; amomum, with a decoction of the plant; centunculus, boiled; or fresh moss steeped in water, and attached to the part till it is quite dry.

The root, too, of lappa boaria, taken in wine, is productive of similar effects. A decoction of cyclaminos in water, is curative of chilblains, and all other affections resulting from cold. For chilblains, cotyledon is also employed with axle-grease, leaves of batrachion, and juice of epithymum. Ladanium, mixed with castoreum, and vervain applied with wine, extract corns from the feet.

Detailed table of contents

CHAP. 67.

MALADIES WHICH ATTACK THE WHOLE OF THE BODY.

Having now finished the detail of the diseases which are perceptible in individual parts of the body, we shall proceed to speak of those which attack the whole of the body. The following I find mentioned as general remedies: in preference to anything else, an infusion of dodecatheos, a plant already described, should be taken in drink, and then the roots of the several kinds of panaces, in maladies of long standing more particularly: seed, too, of panaces should be used for intestinal complaints. For all painful affections of the body we find juice of scordium recommended, as also that of betony: this last, taken in a potion, is particularly excellent for removing a wan and leaden hue of the skin, and for improving its general appearance.

Detailed table of contents

CHAP. 68.

THE GERANION, MYRRHIS, OR MYRTIS; THREE VARIETIES OF IT: SIX REMEDIES.

The plant geranion has the additional names of “myrrhis” and “myrtis.” It is similar to hemlock in appearance, but has a smaller leaf and a shorter stem, rounded, and of a pleasant taste and odour. Such, at all events, is the description given of it by our herbalists; but the Greeks speak of it as bearing leaves a little whiter than those of the mallow, thin downy stems, and branches at intervals some two palms in length, with small heads at their extremities, in the midst of the leaves, resembling the bill of a crane. There is also another variety of this plant, with leaves like those of the anemone, but with deeper incisions, and a root rounded like an apple, sweet, and extremely useful and refreshing for invalids when recovering their strength; this last would almost seem to be the true geranion.

For phthisis this plant is taken, in the proportion of one drachma to three cyathi of wine, twice a day; as also for flatulency. Eaten raw, it is productive of similar effects. The juice of the root is remedial for diseases of the ear; and for opisthotony the seed is taken in drink, in doses of four drachmæ, with pepper and myrrh. Juice of plantago, taken in drink is curative of phthisis, and a decoction of it is equally good for the purpose. Plantago taken as a food with oil and salt immediately after rising in the morning, is extremely refreshing; it is prescribed, too, in cases of atrophy, on alternate day. Betony is given with honey, in the form of an electuary, for phthisis, in pieces the size of a bean; agaric, too, is taken in doses of two oboli in raisin wine, or else daucus with the greater centaury in wine. For the cure of phagedæna, a <*>une given in common to bulimia and to a corrosive kind of ulcer, tithymalos is taken in combination with sesame.

Detailed table of contents

CHAP. 69.

THE ONOTHERAS OR ONEAR: THREE REMEDIES.

Among the various evils by which the whole of the body in common is afflicted, that of wakefulness is the most common. Among the remedies for it we find panaces mentioned, clymenus, and aristolochia, the odour of the plant being inhaled and the head rubbed with it. Aizoü, or houseleek, is beneficial, wrapped in black cloth and placed beneath the pillow, without the patient being aware of it. The onotheras too, or onear, taken in wine, has certain exhilarating properties; it has leaves like those of the almond tree, a rose-coloured flower, numerous branches, and a long root, with a xinous smell when dried: an infusion of this root has a soothing effect upon wild beasts even.

For fits of indigestion attended with nausea, betony is taken in drink: used similarly after the evening meal, it facilitates the digestion. Taken in the proportion of one drachma to three cyathi of oxymel, it dispels crapulence. The same is the case, too, with agaric, taken in warm water after eating. Betony is curative of paralysis, it is said; the same, too, with brais, as already stated. This last is good, too, for numbness of the limbs : the same being the case with argemonia, a plant which disperses those affections which might otherwise necessitate the application of the knife.

Detailed table of contents

CHAP. 70.

REMEDIES FOR EPILEPSY.

Epilepsy is cured by the root of the panaces which we have spoken of as the “heraclion,” taken in drink with sea-calf’s rennet, the proportions being three parts of panaces and one of rennet. For the same purpose an infusion of plantago is taken, or else betony or agaric, with oxymel, the former in doses of one drachma, the latter in doses of three oboli; leaves of cinquefoil are taken, also, in water. Archezostis is also curative of epilepsy, but it must be taken constantly for a year; root of bacchar, too, dried and powdered, and taken in warm water, in the proportion of three cyathi to one cyathus of coriander; centunculus also, bruised in vinegar, warm water, or honey; vervain, taken in wine; hyssop berries, three in number, pounded and taken in water, for sixteen days consecutively; peucedanum, taken in drink with sea-calf’s rennet, in equal proportions; leaves of cinquefoil, bruised in wine and taken for thirty days; powdered betony, in doses of three denarii, with one cyathus of squill vinegar and an ounce of Attic honey; as also scammony, in the proportion of two oboli to four drachmæ of castoreum.

Detailed table of contents

CHAP. 71.

REMEDIES FOR FEVERS.

Agaric, taken in warm water, alleviates cold fevers: sideritis, in combination with oil, is good for tertian fevers; bruised ladanum also, which is found in corn fields; plantago, taken in doses of two drachmæ, in hydromel, a couple of hours before the paroxysms come on; juice of the root of plantago made warm or subjected to pressure; or else the root itself beaten up in water made warm with a hot iron. Some medical men prescribe three roots of plantago, in three cyathi of water; and in a similar manner, four roots for quartan fevers. When buglossos is beginning to wither, if a person takes the pith out of the stem, and says while so doing, that it is for the cure of such and such a person suffering from fever, and then attaches seven leaves to the patient, just before the paroxysms come on, he will experience a cure, they say.

Fevers too, those which are attended with recurrent cold shiverings more particularly, are cured by administering one drachma of betony, or else agaric, in three cyathi of hydromel. Some medical men recommend three leaves of cinquefoil for tertian, four for quartan, and an increased number for other fevers; while others again prescribe in all cases three oboli of cinquefoil, with pepper, in hydromel.

Vervain, administered in water, is curative of fever, in beasts of burden even; but care must be taken, in cases of tertian fever, to cut the plant at the third joint, and of quartan fever at the fourth. The seed of either kind of hypericons is taken also for quartan fevers and cold shiverings. Powdered betony modifies these fits, and panaces is of so warming a nature that persons when about to travel amid the snow are recommended to drink an infusion of it, and to rub the body all over with the plant. Aristolochia also arrests shivering produced by cold.

[Detailed table of contents](#)

CHAP. 72.

REMEDIES FOR PHRENITIS, LETHARGY, AND CARBUNCLES.

Phlebitis is cured by sleep induced by the agency of an infusion of peucedanum in vinegar, poured upon the head, or else by the juice of either kind of anagallis. On the other hand, when patients are suffering from lethargy, it is with the greatest difficulty that they are aroused; a result which may be effected, they say, by touching the nostrils with juice of peucedanum in vinegar. For the cure of insanity, betony is administered in drink. Panaces brings carbuncles to a head, and makes them break; and they are equally cured by powdered betony applied in water, or else cabbage leaves mixed with frankincense in warm water, and taken in considerable quantities. For a similar purpose, a red-hot coal is extinguished in the patient's presence, and the ashes are taken up with the finger and applied to the sore. Bruised plantago is also used for the cure of carbuncles.

[Detailed table of contents](#)

CHAP. 73.

REMEDIES FOR DROPSY. ACTE OR EBULUM. CHAMÆACTE.

For the cure of dropsy, tithymalos characias is employed; panaces also; plantago, used as a diet, dry bread being eaten first, without any drink; betony, taken in doses of two drachme in two cyathi of ordinary wine or honied wine; agaric or seed of lonchitis, in doses of two spoonfuls, in water; psyllion, taken in wine; juice of either anagallis; root of cotyledon in honied wine; root of ebulum, fresh gathered, with the mould shaken off, but not washed in water, a pinch in two fingers being taken in one hemina of old wine mulled; root of trefoil, taken in doses of two drachmæ in wine; the tithymalos known as “platyphyllos;” seed of the hypericon, otherwise known as “caros;” the plant called “acte” — the same thing as ebulum according to some — the root of it being pounded in three cyathi of wine, if there are no symptoms of fever, or the seed of it being administered in red wine; a good handful of vervain also, boiled down in water to one half. But of all the remedies for this disease, juice of chamæacte is looked upon as by far the most efficacious.

Morbid or pituitous eruptions are cured by the agency of plantago, or else root of cyclaminos with honey. Leaves of ebulum, bruised in old wine and applied topically, are curative of the disease called “boa,” which makes its appearance in the form of red pimples. Juice of strychnos, applied as a liniment, is curative of prurigo.

Detailed table of contents

CHAP. 74.

REMEDIES FOR ERYSIPELAS.

For the cure of erysipelas, aizoüm is used, or else pounded leaves of hemlock, or root of mandragora; this last being cut into round slices like cucumber and suspended over must, after which it is hung up in the smoke, and then pounded in wine or vinegar. It is a good plan too to use fomentations with myrtle wine: two ounces of mint beaten up in vinegar with one ounce of live sulphur, form a mixture sometimes employed; as also soot mixed with vinegar.

There are several kinds of erysipelas, one in particular which attacks the middle of the body, and is known as “zoster:” should it entirely surround the body, its effects are fatal. For this disease, plantago is remedial, mixed with Cimolian chalk; vervain, used by itself; or root of persolata. For other kinds of erysipelas of a spreading nature, root of cotyledon is used, mixed with honied wine; aizoüm also, or juice of linozostis, in combination with vinegar.

Detailed table of contents

CHAP. 75. (12.)

REMEDIES FOR SPRAINS.

For the cure of sprains, root of polypodion is used, in the form of a liniment: the pain and swelling are modified also by using seed of psyllion; leaves of plantago beaten up with a little salt; seed of verbascum, boiled in wine and pounded; or hemlock with axle-grease. Leaves of ephemeron are applied topically to tumours and tuberosities, so long as they are capable of being dispersed.

[Detailed table of contents](#)

CHAP. 76.

REMEDIES FOR JAUNDICE.

It is upon the eyes in particular that jaundice is productive of so remarkable an effect; the bile penetrating between the membranes, so extremely delicate as they are and so closely united. Hippocrates tells us that the appearance of jaundice on or after the seventh day in fevers is a fatal symptom; but I am acquainted with some instances in which the patients survived after having been reduced to this apparently hopeless state. We may remark also, that jaundice sometimes comes on without fever supervening. It is combated by taking the greater centaury, as already mentioned, in drink; agaric, in doses of three oboli in old wine; or leaves of vervain, in doses of three oboli, taken for four consecutive days in one hemina of mulled wine. But the most speedy cure of all is effected by using juice of cinquefoil, in doses of three cyathi, with salt and honey. Root of cyclaminos is also taken in drink in doses of three drachmæ, the patient sitting in a warm room free from all cold and draughts, the infusion expelling the bile by its action as a sudorific.

Leaves of tussilago are also used in water for this purpose; the seed of either kind of linozostis, sprinkled in the drink, or made into a decoction with chick-pease or wormwood: hyssop berries taken in water; the plant lichen, all other vegetables being carefully abstained from while it is being used; polythrix, taken in wine; and struthion, in honied wine.

Detailed table of contents

CHAP. 77.

REMEDIES FOR BOILS.

There are boils also, known as “furunculi,” which make their appearance indiscriminately on all parts of the body, and are productive of the greatest inconvenience: sometimes indeed, when the constitution is exhausted, they are fatal in their effects. For their cure, leaves of pycnocomon are employed, beaten up with polenta, if the boil has not come to a head. They are dispersed also by an application of leaves of ephedron.

Detailed table of contents

CHAP. 78.

REMEDIES FOR FISTULA.

Fistulas, too, insidiously attack all parts of the body, owing to unskilfulness on the part of medical men in the use of the knife. The smaller centaury is used for their cure, with the addition of lotions and boiled honey: juice of plantago is also employed, as an injection; cinquefoil, mixed with salt and honey; ladanum, combined with castoreum; cotyledon, applied hot with stag's marrow; pith of the root of verbascum reduced to a liquid state in the shape of a lotion, and injected; root of aristolochia; or juice of tithymalos.

[Detailed table of contents](#)

CHAP. 79.

REMEDIES FOR ABSCESSSES AND HARD TUMOURS.

Abscesses and inflammations are cured by an application of leaves of argemonia. For indurations and gatherings of all descriptions a decoction of vervain or cinquefoil in vinegar is used; leaves or root of verbascum; a liniment made of wine and hyssop; root of acoron, a decoction of it being used as a fomentation; or else aizoüm. Contusions also, hard tumours, and fistulous abscesses are treated with illecebra.

All kinds of foreign substances which have pierced the flesh are extracted by using leaves of tussilago, daucus, or seed of leontopodium pounded in water with polenta. To suppurations, leaves of pycnocomon are applied, beaten up with polenta, or else the seed of that plant, or orchis. An application of root of satyrion is said to be a most efficacious remedy for deep-seated diseases of the bones. Corrosive ulcers and all kinds of gatherings are treated with sea-weed, used before it has dried. Root, too, of alcima disperses gatherings.

[Detailed table of contents](#)

CHAP. 80.

REMEDIES FOR BURNS.

Burns are cured by the agency of plantago, or of arction, so effectually indeed as to leave no scar. The leaves of this last plant are boiled in water, beaten up, and applied to the sore. Roots of cyclaminos are used, in combination with aizoüm; the kind of hypericon also, which we have mentioned as being called “corissum.”

Detailed table of contents

CHAP. 81.

REMEDIES FOR DISEASES OF THE SINEWS AND JOINTS.

For diseases of the sinews and joints, plantago, beaten up with salt, is a very useful remedy, or else argemonia, pounded with honey. Patients affected with spasms or tetanus are rubbed with juice of peucedanum. For indurations of the sinews, juice of ægilops is employed, and for pains in those parts of the body erigeron or epithymum, used as a liniment, with vinegar. In cases of spasms and opisthotony, it is an excellent plan to rub the part affected with seed of the hype- ricon known as “caros,” and to take the seed in drink. Phrynion, it is said, will effect a cure even when the sinews have been severed, if applied instantaneously, bruised or chewed. For spasmodic affections, fits of trembling, and opisthotony, root of alcima is administered in hydromel; used in this manner, it has a warming effect when the limbs are benumbed with cold.

Detailed table of contents

CHAP. 82.

REMEDIES FOR HÆMORRHAGE.

The red seed of the plant called “pæmonia” arrests hæmorrhage; the root also is possessed of similar properties. But it is clymenus that should be employed, when there are discharges of blood at the mouth or nostrils, from the bowels, or from the uterus. In such cases, lysimachia also is taken in drink, applied topically, or introduced into the nostrils; or else seed of plantago, or cinquefoil, is taken in drink, or employed in the form of a liniment. Hemlock seed is introduced into the nostrils, for discharges of blood there, or else it is pounded and applied in water; aizoüm also, and root of astragalus. Ischæmon and achillea likewise arrest hæmorrhage.

Detailed table of contents

CHAP. 83. (13.)

HIPPURIS, OTHERWISE CALLED EPHEDRON, ANABASIS, OR EQUISÆTUM;
THREE KINDS OF IT: EIGHTEEN REMEDIES.

Equisætum, a plant called “hippuris” by the Greeks, and which we have mentioned in terms of condemnation, when treating of meadow lands — it being, in fact, a sort of hair of the earth, similar in appearance to horse-hair — is used by runners for the purpose of diminishing the spleen. For this purpose it is boiled down in a new earthen vessel to one third, the vessel being filled to the brim, and the decoction taken in doses of one hemina for three successive days. It is strictly forbidden, however, to eat any food of a greasy nature the day before taking it.

Among the Greeks there are various opinions in relation to this plant. According to some, who give it the same name of “hippuris,” it has leaves like those of the pine tree, and of a swarthy hue; and, if we are to believe them, it is possessed of virtues of such a marvellous nature, that if touched by the patient only, it will arrest hæmorrhage. Some authorities call it “hippuris,” others, again, “ephedron,” and others “anabasis;” and they tell us that it grows near trees, the trunks of which it ascends, and hangs down therefrom in numerous tufts of black, rush-like hair, much like a horse’s tail in appearance. The branches, we are told, are thin and articulated, and the leaves, few in number, small, and thin, the seed round, and similar to coriander in appearance, and the root ligneous: it grows, they say, in plantations more particularly.

This plant is possessed of astringent properties. The juice of it, kept in the nostrils, arrests bleeding therefrom, and it acts astringently upon the bowels. Taken in doses of three cyathi, in sweet wine, it is a cure for dysentery, is an efficient diuretic, and is curative of cough, hardness of breathing, ruptures, and serpiginous affections. For diseases of the intestines and bladder, the leaves are taken in drink; it has the property, also, of reducing ruptures of the groin.

The Greek writers describe another hippuris, also, with shorter tufts, softer and whiter. This last, they say, is remarkably good for sciatica, and, applied with vinegar, for wounds, it having the property of stanching the blood. Bruised nym-phæa is also applied to wounds. Peucedanum is taken in drink with cypress seed, for discharges of blood at the mouth or by the lower passages. Sideritis is possessed of such remarkable virtues, that applied to the wound of a gladiator just inflicted, it will stop the flow of blood; an effect which is equally produced by an application of charred fennel-giant, or of the ashes of that plant. For a similar purpose, also, the fungus that is found growing near the root of fennel-giant is still more efficacious.

CHAP. 84.

STEPHANOMELIS.

For bleeding at the nostrils, seed of hemlock, pounded in water, is considered efficacious, as also stephanomelis, applied with water. Powdered betony, taken with goat's milk, or bruised plantago, arrests discharges of blood from the ma- millæ. Juice of plantago is administered to patients when vomiting blood. For local discharges of blood, an application of root of persolata with stale axle-grease is highly spoken of.

[Detailed table of contents](#)

CHAP. 85.

REMEDIES FOR RUPTURES AND CONVULSIONS. ERYSITHALES: ONE REMEDY.

For ruptures, convulsions, and falls with violence, the greater centaury is used; root of gentian pounded or boiled; juice of betony — this last being employed also for ruptures produced by straining the vocal organs or sides — panaces; scordium; or aristolochia taken in drink. For contusions and falls, agaric is taken, in doses of two oboli, in three cyathi of honied wine, or if there are symptoms of fever, hydromel; the verbascum, also, with a golden flower; root of acoron the several varieties of Aizoûm, the juice of the larger kind being particularly efficacious; juice of symphytum, or a decoction of the root of that plant; daucus, unboiled; erysithales, a plant with a yellow flower and a leaf like that of acanthus, taken in wine; chamærops; irio, taken in pottage; plantago taken any way, as also * * * *

Detailed table of contents

CHAP. 86.

REMEDIES FOR PHTHIRIASIS.

Phthiriasis is a disease which proved fatal to the Dictator Sylla, and which developes itself by the production of insects in the blood, which ultimately consume the body. It is combated by using the juice of Taminian grapes or of hellebore, the body being rubbed all over with it, in combination with oil. A decoction of Taminian grapes in vinegar, has the effect, also, of ridding the clothes of these vermin.

Detailed table of contents

CHAP. 87. (14.)

REMEDIES FOR ULCERS AND WOUNDS.

Of ulcers there are numerous kinds, which are treated in various ways. The root of all the varieties of panaces is used as an application for running ulcers, in warm wine.

That which we have spoken of as the “chironion” is particularly good as a desiccative: bruised with honey, it opens tumours, and is useful for serpiginous ulcers, the cure of which appears more than doubtful; in which case it is amalgamated with flower of copper tempered with wine, either the seed, flower, or root, being employed for the purpose. Mixed with polenta it is good for old wounds. The following are also good detergents for wounds: heraclion siderion, apollinaris, psyllion, tragacantha, and scordotis mixed with honey. Powdered scordotis applied by itself, consumes fleshy excrescences on the body. Polemonia is curative of the malignant ulcer known as “cacoëthes.” The greater centaury, sprinkled in powder, or applied in the form of a liniment, or the leaves of the smaller centaury, boiled or pounded, act as a detergent upon inveterate ulcers, and effect a cure. To recent wounds, the follicles of the clymenus are applied. Gentian is applied to serpiginous ulcers, the root being bruised or else boiled down in water to the consistency of honey; the juice also of the plant is employed. For wounds, a kind of lycium is prepared from gentian.

Lysimachia is curative of recent wounds, and plantago of all kinds of ulcerations, those on females, infants, and aged persons more particularly. This plant, when softened by the action of fire, is better still: in combination with cerate it acts as a detergent upon ulcers with indurated edges, and arrests the progress of corrosive sores: when applied bruised, it should be covered with its own leaves. Chelidonia also acts as a desiccative upon suppurations, abscesses, and fistulous ulcers; indeed, it is so remarkably useful for the cure of wounds, as to be employed as a substitute for spodium even. In cases where the cure is almost hopeless, it is applied with axle-grease. Dittany, taken internally, causes arrows to fall from the flesh; used as a liniment, it has the effect of extracting other kinds of pointed weapons: the leaves are taken in the proportion of one obolus to one cyathus of water. Nearly equal in its efficacy is pseudo-dictamnion: they are both of them useful, also, for dispersing suppurations.

Aristolochia cauterizes putrid sores, and, applied with honey, acts as a detergent upon sordid ulcers. At the same time also, it removes maggots, and extracts hard cores, and all foreign bodies adhering to the flesh, arrows more particularly, and, applied with resin, splintered bones. Used by itself, it fills the cavities made by ulcers with new flesh, and, employed with iris, in vinegar, it closes recent wounds. Vervain, or cinquefoil with salt and honey, is

remedial for ulcers of long standing. Roots of persolata are applied to recent wounds inflicted with iron, but for old wounds, it is the leaves that are employed: in both cases, in combination with axle-grease, the sore being then covered with the leaves of the plant. Damasonium is used for wounds the same way as for scrofula, and leaves of verbascum are employed with vinegar or wine.

Vervain is useful for all kinds of callosities or putrid sores; root of nymphæa heraclia is curative of running ulcers; and the same is the case with root of cyclaminos, either used by itself, or in combination with vinegar or honey. This last root is useful also for the cure of steatomatous tumours, and hyssop for that of running ulcers; an effect equally produced by peucedanum, a plant which exercises so powerful an influence upon fresh wounds, as to cause exfoliation even of the bones. The two varieties of anagallis are possessed of similar properties, and act as a check upon the corrosive sores known as “nomæ” and upon defluxions; they are useful also in cases of recent wounds, those of aged people in particular. Fresh leaves of mandragora, applied with cerate, are curative of apostemes and sordid ulcers: the root too is used, with honey or oil, for wounds.

Hemlock, incorporated with flour of winter wheat by the agency of wine — as also the plant Aizoïum — is curative of herpetic eruptions, and corrosive or putrid sores. Erigeron is employed for ulcers which breed maggots. Root of astra- galus is used for the cure of recent wounds or of ulcers of long standing; and upon these last either kind of hypocisthis acts as a detergent. Seed of leontopodium, bruised in water and applied with polenta, extracts pointed weapons from the flesh: a result equally produced by using seed of pyncocomon. The tithymalos characias supplies its juice for the cure of gangrenes, phagedænic sores, and putrid ulcers; or else a decoction is made of the branches with polenta and oil. Roots of orchis have a similar effect; in addition to which, ‘applied, either dry or fresh gathered, with honey and vinegar, they are curative of the ulcer known as “cacoëthes.”’ Onothera also, used by itself; is curative of ulcers when rapidly gaining head.

The people of Scythia employ scythice for the treatment of wounds. For carcinoma, argemonia, applied with honey, is extremely efficacious. For sores that have prematurely closed, root of asphodel is boiled, in manner already stated. and then beaten up with polenta, and applied. For all kinds of wounds apollinaris is very useful. Root of astragalus, reduced to powder, is good for running ulcers; the same, too, with callithrix, boiled in water. For blisters, more particularly when caused by the shoes, vervain is used, as also pounded lysimachia, or nymphæa dried and powdered; but when they have assumed the form of inveterate ulcers, polythrix will be found more serviceable.

CHAP. 88.

POLYCNEMON: ONE REMEDY.

Polycnemon is a plant which resembles cunila bubula; it has a seed like that of pennyroyal, a ligneous stem with numerous articulations, and odoriferous umbels, with a pleasant though pungent smell. This plant is chewed and applied to wounds inflicted with iron, the application being removed at the end of four days. Symphyton causes sores to cicatrize with the greatest rapidity; the same, too, with sideritis, which is applied in combination with honey. The seed and leaves of verbascum, boiled in wine and pounded, are used for the extraction of all foreign substances adhering to the body; and a similar use is made of leaves of mandragora mixed with polenta, and roots of cyclaminos with honey. Leaves of trixago, bruised in oil, are used for ulcers of a serpiginous nature more particularly, as also sea-weed bruised with honey. Betony, with the addition of salt, is employed for the cure of carcinomatous sores and inveterate blisters on the neck.

[Detailed table of contents](#)

CHAP. 89.

REMEDIES FOR WARTS. AND APPLICATIONS FOR THE REMOVAL OF SCARS.

Argemonia with vinegar, or root of batrachion, removes warts; this last having the effect also of bringing off malformed nails. The juice or the leaves, applied topically, of either kind of linozostis, remove warts. All the varieties of tithymalos are efficacious for the removal of every kind of wart, as also of hangnails and wens. Ladanum imparts a fresh colour and seemly appearance to scars.

(15.) The traveller who carries artemisia attached to his person, or elelisphacus, will never be sensible of lassitude, it is said.

Detailed table of contents

CHAP. 90.

REMEDIES FOR FEMALE DISEASES.

One great remedy for all female diseases in common, is the black seed of the herbaceous plant *pæonia*, taken in hydro- mel: the root also is an effectual emmenagogue. Seed of *panaces*, mixed with wormwood, acts as an emmenagogue and as a sudorific: the same, too, with *scordotis*, taken internally or applied topically. *Betony*, in doses of one drachma to three cyathi of wine, is taken for various affections of the uterus, as also directly after child-birth. Excessive menstruation is arrested by a pessary of *achillea*, or else a sitting-bath composed of a decoction of that plant. Seed of *henbane* in wine is used as a liniment for diseases of the *mamillæ*, and the root is employed in the form of a plaster for uterine affections; *chelidonia*, too, is applied to the *mamillæ*.

Roots of *panaces*, applied as a pessary, bring away the after-birth and the dead foetus, and the plant itself, taken in wine, or used as a pessary with honey, acts as a detergent upon the uterus. *Polemonia*, taken in wine, brings away the after-birth; used as a fumigation, it is good for suffocations of the uterus. Juice of the smaller *centaury*, taken in drink, or employed as a fomentation, acts as an emmenagogue. The root also of the larger *centaury*, similarly used, is good for pains in the uterus; scraped and used as a pessary, it expels the dead foetus. For pains of the uterus, *plantago* is applied as a pessary, in wool, and for hysterical suffocations, it is taken in drink. But it is *dittany* that is of the greatest efficacy in cases of this description; it acts as an emmenagogue, and is an expellent of the foetus when dead or lying transversely in the uterus. In these cases the leaves of it are taken, in doses of one obolus, in water: indeed so active is it in its effects that ordinarily it is forbidden to be introduced into the chamber of a woman lying-in. Not only is it thus efficacious when taken in drink, but even when applied topically or used as a fumiga- tion. *Pseudodictamnium* possesses pretty nearly the same virtues, but it acts as an emmenagogue also, boiled in doses of one denarius in unmixed wine. *Aristolochia*, however, is employed for a greater number of purposes: in combination with *myrrh* and pepper, either taken in drink or used as a pessary, it acts as a powerful emmenagogue, and brings away the dead foetus and the after-birth. This plant, the smaller kind in particular, used either as a fomentation, fumigation, or pessary, acts as a preventive of procidence of the uterus.

Hysterical suffocations and irregularities of the catamenia are treated with *agarc*, taken in doses of three oboli, in one cyathus of old wine: *vervain* is used also in similar cases, as a pessary, with fresh hog's lard; or else *antirrhinum*, with rose oil and honey. Root of *Thessalian nymphæa*, used as a pessary, is curative of pains in the uterus; taken in red wine, it arrests uterine

discharges. Root of cyclaminos, on the other hand, taken in drink and employed as a pessary, acts as an emmenagogue: a decoction of it, used as a sitting-bath, cures affections of the bladder. Cissanthemos, taken in drink, brings away the after-birth, and is curative of diseases of the uterus. The upper part of the root of xiphion, taken in doses of one drachma, in vinegar, promotes menstruation. A fumigation of burnt peucedanum has a soothing effect in cases of hysterical suffocation. Psyllion, taken in the proportion of one drachma to three cyathi of hydromel, is particularly good for promoting the lochial discharge. Seed of mandragora, taken in drink, acts as a detergent upon the uterus; the juice, employed in a pessary, promotes menstruation and expels the dead fetus. The seed of this plant, used with live sulphur, arrests menstruation when in excess; while batrachion, on the other hand, acts as an emmenagogue. This last plant is either used as an article of food, or is taken in drink: in a raw state, as already stated, it has a burning flavour; but when cooked, the taste of it is greatly improved by the addition of salt, oil, and cummin. Daucus, taken in drink, promotes the catamenia, and is an expellent of the after-birth in a very high degree. Ladanum, used as a fumigation, acts as a corrective upon the uterus, and is employed topically for pains and ulcerations of that organ.

Scammony, taken in drink or used as a pessary, is an expellent of the dead fœtus. Either kind of hypericon, used as a pessary, promotes menstruation: but for this purpose it is crethmos, according to Hippocrates, that is the most efficacious, the seed or root of it being taken in wine. of the outer coat brings away the after-birth. This plant, taken in water, is good for hysterical suffocations; root of geranion also, which is peculiarly useful for the after-birth, and for inflation of the uterus. Hippuris, taken in drink or applied as a pessary, acts as a detergent upon the uterus: polygonos, taken in drink, promotes menstruation; and the same with root of alcima. Leaves of plantago, and agaric in hydromel, have a similar effect. Artemisia, bruised and applied as a pessary, with oil of iris, figs, or myrrh, is curative of diseases of the uterus; the root, too, of this plant, taken in drink, is so strongly purgative as to expel the dead fœtus even. A decoction of the branches, used as a sitting-bath, promotes menstruation and brings away the after-birth; the same, too, with the leaves, taken in doses of one drachma in drink. The leaves, if applied to the lower regions of the abdomen with barley-meal, will prove equally efficacious.

Acoron is very useful for internal complaints of females; as also the two varieties of conyza, and crethmos. Either kind of anthyllis, taken in wine, is remarkably good for uterine affections, griping pains in that organ, and retardations of the after-birth. Callithrix, applied as a fomentation, is curative of affections of the vagina: it removes scaly eruptions also of the head, and, beaten up in oil, it stains the hair. Geranion, taken in white wine, or hypocisthis in red, arrests all uterine discharges. Hyssop modifies hysterical suffocations. Root of vervain, taken in water, is a most excellent remedy for

all accidents incident to, or consequent upon, delivery. Some persons mix bruised cypress seed with peucedanum in red wine. Seed, too, of psyllion, boiled in water and taken warm, has a soothing effect upon all defluxions of the uterus. Symphyton, bruised in wine, promotes menstruation. Juice of scordotis, in the proportion of one drachma to four cyathi of hydromel, accelerates delivery. Leaves of dittany are given for the same purpose, in water, with remarkable success. It is a well-known fact, too, that these leaves, to the extent of a single obolus even, will bring away the fœtus instantaneously, even when dead, without the slightest inconvenience to the patient. Pseudodictamnium is productive of a somewhat similar effect, but not in so marked a degree: cyclaminos, too, attached as an amulet; cissanthemos, taken in drink; and powdered betony, in hydromel.

CHAP. 91.

ARSENOGONON: ONE MEDICINAL PROPERTY. THELY- GONON: ONE MEDICINAL PROPERTY.

Arsenogonon and thelygonon are plants, both of them, with clusters resembling the blossoms of the olive, but paler, and a white seed like that of the poppy. By taking thelygonon in drink, they say, the conception of female issue is ensured. Arsenogonon differs from it in the seed, which resembles that of the olive, but in no other respect. By taking this last plant in drink, male issue may be ensured — that is, if we choose to believe it. Some persons, however, assert that both plants resemble ocimum, but that the seed of arsenogonon is double, and resembles the testes in appearance.

[Detailed table of contents](#)

CHAP. 92.

MASTOS: ONE REMEDY.

Aizoüm, which we have spoken of under the name of digi- tellus, is the great specific for diseases of the mamillæ. The milk is increased by taking erigeron in raisin wine, or else sonchos boiled with spelt. The plant known as “mastos,” applied topically, removes the hairs from the mamillæ, which make their appearance after child-birth: it has the effect also of dispersing scaly crusts upon the face, and other cutaneous affections. Gentian also, nymphæa heraclia employed in a liniment, and root of cyclaminos, remove all blemishes of the skin. Seeds of cacalia, mixed with melted wax, plump out the skin of the face and make wrinkles disappear. Root of acoron, also, removes all spots upon the skin.

Detailed table of contents

CHAP. 93.

APPLICATIONS FOR THE HAIR. LYSIMACHIA. OPHRYS.

Lysimachia imparts a blonde tint to the hair, and the hypericon, otherwise called “corisson,” makes it black. The same too, with ophrys, a plant with indentations, which resembles the cabbage, but has only two leaves. Polemonia, too, boiled in oil, imparts blackness to the hair.

As for depilatories, I reckon them in the number of cosmetics, fit for women only, though men use them now-a-days. For this purpose archezostis is looked upon as highly efficacious, as also juice of tithymalos, applied with oil every now and then in the sun, or after pulling out the hairs. Hyssop, applied with oil, heals itch-scab in beasts, and side-citis is particularly useful for quinzey in swine.

But let us now turn to the remaining plants of which we have to speak.

SUMMARY. — Remedies, narratives, and observations, one thousand and nineteen.

ROMAN AUTHORS QUOTED. — M. Varro, C. Valgius, Pompeius Lenæus, Sextius Niger who wrote in Greek, Julius Bassus who wrote in Greek, Antonius Castor, Cornelius Celsus.

FOREIGN AUTHORS QUOTED. — Theophrastus, Democritus, Juba, Orpheus, Pythagoras, Mago, Menander who wrote the “Biochresta,” Nicander, Homer, Hesiod, Musæus, Sophocles, Xanthus, Anaxilaüs.

MEDICAL AUTHORS QUOTED. — Mnesitheus, Callimachus, Phantias the physician, Timaristus, Simus, Hippocrates, Chrysippus, Diocles, Ophelion, Heraclides, Hicesius, Dionysius, Apollodorus of Citium, Apollodorus of Tarentum, Praxagoras, Plistonicus, Medius, Dieuches, Cleophrantus, Philistion, Asclepiades, Creteuas, Petronius Diadotus, Iollas, Erasistratus, Diagoras, Andreas, Mnesides, Epicharmus, Damion, Tlepolemus, Metrodorus, Solo, Lycus, Olympias of Thebes, Philinus, Petrichus, Micton, Glaucias, Xenocrates.

**BOOK XXVII. A DESCRIPTION OF PLANTS, AND
OF THE REMEDIES DERIVED FROM THEM.**

Detailed table of contents

CHAP. 1. (1.)

RESEARCHES OF THE ANCIENTS UPON THIS SUBJECT.

THE further I proceed in this work, the more I am impressed with admiration of the ancients; and the greater the number of plants that remain to be described, the more I am induced to venerate the zeal displayed by the men of former times in their researches, and the kindly spirit manifested by them in transmitting to us the results thereof. Indeed their bounteousness in this respect would almost seem to have surpassed the munificent disposition even of Nature herself, if our knowledge of plants had depended solely upon man's spirit of discovery: but as it is, it is evident beyond all doubt that this knowledge has emanated from the gods themselves, or, at all events, has been the result of divine inspiration, even in those cases where man has been instrumental in communicating it to us. In other words, if we must confess the truth — a marvel surpassed by nothing in our daily experience — Nature herself, that common parent of all things, has at once produced them, and has discovered to us their properties.

Wondrous indeed is it, that a Scythian plant should be brought from the shores of the Palus Mæotis, and the euphorbia from Mount Atlas and the regions beyond the Pillars of Hercules, localities where the operations of Nature have reached their utmost limit! That in another direction, the plant britannica should be conveyed to us from isles of the Ocean situate beyond the confines of the earth! That the æthiopis should reach us from a climate scorched by the luminaries of heaven! And then, in addition to all this, that there should be a perpetual interchange going on between all parts of the earth, of productions so instrumental to the welfare of mankind! Results, all of them, ensured to us by the peace that reigns under the majestic sway of the Roman power, a peace which brings in presence of each other, not individuals only, belonging to lands and nations far separate, but mountains even, and heights towering above the clouds, their plants and their various productions! That this great bounteousness of the gods may know no end, is my prayer, a bounteousness which seems to have granted the Roman sway as a second luminary for the benefit of mankind.

Detailed table of contents

CHAP. 2. (2.)

ACONITE, OTHERWISE CALLED THELYPHONON, CAM- MARON,
PARDALIANCHES, OR SCORPIO; FOUR REMEDIES.

But who, I say, can sufficiently venerate the zeal and spirit of research displayed by the ancients? It is they who have shown us that aconite is the most prompt of all poisons in its effects — so much so indeed, that female animals, if the sexual parts are but touched with it, will not survive a single day. With this poison it was that M. Cæcilius accused Calpurnius Bestia of killing his wives in their sleep, and this it was that gave rise to that fearful peroration of his, denouncing the murderous finger of the accused. According to the fables of mythology, this plant was originally produced from the foam of the dog Cerberus, when dragged by Hercules from the Infernal Regions; for which reason, it is said, it is still so remarkably abundant in the vicinity of Heraclea in Pontus, a spot where the entrance is still pointed out to the shades below.

And yet, noxious as it is, the ancients have shown us how to employ aconite for the benefit of mankind, and have taught us as the result of their experience, that, taken in mulled wine, it neutralizes the venom of the scorpion: indeed such is the nature of this deadly plant, that it kills man, unless it can find in man something else to kill. When such is the case, as though it had discovered in the body a fit rival to contend with, that substance is the sole object of its attack; finding another poison in the viscera, to it alone it confines its onslaught; and thus, a truly marvellous thing! two poisons, each of them of a deadly nature, destroy one another within the body, and the man survives. Even more than this, the ancients have handed down to us remedies employed by the animals themselves, and have shown how that venomous creatures even effect their own cure. By the contact of aconite the scorpion is struck with torpor, is quite benumbed, assumes a pallid hue, and so confesses itself vanquished. When this is the case, white hellebore is its great auxiliary: the very touch of it dispels its torpor, and the aconite is forced to yield before two foes, its own enemy and the common enemy of all.

Now, after this, if any one should be of opinion that man could, by any chance or possibility, make such discoveries as these, he must surely be guilty of ingratitude in thus appreciating the beneficence of the gods! In countries frequented by the panther, they rub meat with aconite, and if one of those animals should but taste it, its effects are fatal: indeed were not these means adopted, the country would soon be overrun by them. It is for this reason, too, that some persons have given to hellebore the name of “pardalianches.” It has been well ascertained, however, that the panther instantaneously recovers if it can find the opportunity of eating human ordure. So far as these animals are concerned, who can entertain a doubt that it was chance only that first led them to this discovery; and that as often as this happens the discovery is only

a mere repetition of the accident, there being neither reason nor an appreciation of experience to ensure its transmission among them?

(3.) It is chance, yes, it is chance that is the Deity who has made to us these numerous revelations for our practical benefit; always understanding that under this name we mean Nature, that great parent and mistress of all things: and this is evident, whether we come to the conclusion, that these wild beasts make the discovery from day to day, or that they are gifted from the first with these powers of perception. Regarded in another point of view, it really is a disgrace that all animated beings should have an exact knowledge of what is beneficial to them, with the exception of man!

The ancients, openly professing their belief that there is no evil without some admixture of good, have asserted that aconite is a remarkably useful ingredient in compositions for the eyes. It may therefore be permitted me, though I have hitherto omitted a description of the poisonous plants, to point out the characteristics of aconite, if only that it may be the more easily detected. Aconite has leaves like those of cyclaminos or of the cucumber, never more than four in number, slightly hairy, and rising from near the root. This root, which is of moderate size, resembles the sea-fish known as the “cammarus,” a circumstance owing to which the plant has received the name of “cammaron” from some; while others, for the reason already mentioned, have called it “thelyphonon.” The root is slightly curved, like a scorpion’s tail, for which reason some persons have given it the name of “scorpio.” Others, again, have preferred giving it the name of “myoctonon,” from the fact that the odour of it kills mice at a considerable distance even.

This plant is found growing upon the naked rocks known as “æonæ;” and hence it is, according to some authorities, that it is called “aconitum,” there being not so much as dust even about it to conduce to its nutriment. Such is the reason given for its name by some: but according to others, it receives this appellation from the fact that it fatally exercises the same effects upon the body that the whetstone does upon the edge of iron, being no sooner employed than its effects are felt.

Detailed table of contents

CHAP. 3. (4.)

-ÆTHIOPIS: FOUR REMEDIES.

Æthiopis is a plant with leaves resembling those of phlomos, large, numerous, hairy, and springing from the root. The stem is square, rough, similar to that of arction in appearance, and with numerous axillary concavities. The seed resembles that of the fitch, being white and twofold; the roots are several in number, long, fleshy, soft, and of a viscous taste; when dry they turn black and hard, and might easily be taken for horns. In addition to Æthiopia, this plant grows upon Mount Ida in Troas, and in Messenia. The roots are gathered in autumn, and left to dry for some days in the sun, to prevent them from turning mouldy. Taken in white wine they are curative of affections of the uterus, and a decoction of them is administered for sciatica, pleurisy, and eruptions of the throat. The kind, however, which comes from Æthiopia, is by far the best, and gives instantaneous relief.

Detailed table of contents

CHAP. 4.

AGERATON: FOUR REMEDIES.

Ageraton is a ferulaceous plant, a couple of palms in height, similar to origanum in appearance, and bearing flowers like balls of gold. Used as a fumigation, this plant acts as a diuretic; and as a detergent upon the uterus, when used in a sitting bath more particularly. Its name has been given to it, from the circumstance that it keeps a very long time without fading.

Detailed table of contents

CHAP. 5.

THE ALOE; TWENTY-NINE REMEDIES.

The aloe bears a resemblance to the squill, except that it is larger, and has more substantial leaves, with streaks running obliquely. The stem is tender, red in the middle, and not unlike that of the anthericus. It has a single root, which runs straight downwards, like a stake driven into the ground; its smell is powerful, and it has a bitter taste. The most esteemed aloes are those imported from India, but it grows in the Asiatic provinces as well. This last kind, however, is never used, except that the leaves are applied fresh to wounds; indeed, these leaves, as well as the juice, are glutinous to a marvellous degree, and it is for this property that it is grown in vessels of a conical form, in the same way as the greater Aizoüm. Some persons make incisions in the stem to obtain the juice, before the seed is ripe, while others, again, make them in the leaves as well. Tearlike drops are also found adhering to it, which exude spontaneously: hence it is that some recommend that the place should be paved where it is grown, to prevent this juice from being absorbed.

Some authors have stated, that there is found in Judæa, beyond Hierosolyma, a mineral aloe, but that it is inferior to the other kinds, being of a darker colour and more humid than any of the rest. Aloes of the finest quality should be unctuous and shining, of a red colour, brittle, compact, like the substance of liver, and easily liquefied. That which is hard and black should be rejected; the same, too, when it is mixed with sand or adulterated with gum and acacia, a fraud which may be easily detected by the taste.

This plant is of an astringent nature, binding, and slightly calorific. It is employed for numerous purposes, but principally as a purgative, it being almost the only one of all the medicines which produce that effect, that is at the same time a good stomachic, and does not exercise the slightest noxious influence upon the stomach. It is taken in doses of one drachma, and, in cases of derangement of the stomach, it is administered two or three times a day, in the proportion of one spoonful to two cyathi of warm or cold water, at intervals, according to the nature of the emergency. As a purgative it is mostly taken in doses of three drachmæ; and it operates still more efficaciously, if food is eaten directly afterwards. Used with astringent wine, it prevents the hair from falling off, the head being rubbed with it the contrary way of the hair, in the sun. Applied to the temples and forehead with rose oil and vinegar, or used as an infusion, in a more diluted form, it allays head-ache. It is generally agreed that it is remedial for all diseases of the eyes, but more particularly for prurigo and scaly eruptions of the eye-lids; as also for marks and bruises, applied in combination with honey, Pontic honey in particular.

It is employed, also, for affections of the tonsillary glands and gums, for all

ulcerations of the mouth, and for spitting of blood, if not in excess — the proper dose being one drachma, taken in water or else vinegar. Used by itself, or in combination with vinegar, it arrests hæmorrhage, whether proceeding front wounds or from other causes. In addition to these properties, it is extremely efficacious for the cure of wounds, producing cicatrization very rapidly: it is sprinkled also upon ulcerations of the male organs, and is applied to condylomata and chaps of the fundament, either in common wine, raisin wine, or by itself in a dry state, according as a mollifying or restrictive treatment is required. It has the effect, also, of gently arresting hæmorrhoidal bleeding, when in excess. In cases of dysentery, it is used as an injection, and where the digestion is imperfect it is taken shortly after the evening meal. For jaundice, it is administered in doses of three oboli, in water. As a purgative for the bowels, it is taken in pills, with boiled honey or turpentine. It is good also for the removal of hangnails. When employed in ophthalmic preparations, it is first washed, that the more gravelly portions of it may subside; or else it is put over the fire in a pipkin, and stirred with a feather from time to time, that the whole of it may be equally warmed.

Detailed table of contents

CHAP. 6.

ALCEA: ONE REMEDY.

Alcea is a plant with leaves, resembling those of vervain, known also as “peristereon,” some three or four stems covered with leaves, a flower like that of the rose, and white roots, at most six in number, a cubit in length, and running obliquely. It grows in a soil that is rich without being dry. The root is given in wine or water, for dysentery, diarrhoea, ruptures, and convulsions.

[Detailed table of contents](#)

CHAP. 7.

THE ALYPON: ONE REMEDY.

The alypon has a small stem, with a soft head, and is not unlike beet in appearance. It has an acrid, viscous taste. extremely pungent and burning. Taken in hydromel, with a little salt, it acts as a purgative. The smallest dose is two drachmæ, a moderate dose, four, and the largest, six. When used as a purgative, it is taken in chicken broth.

[Detailed table of contents](#)

CHAP. 8.

ALSINE, A PLANT USED FOR THE SAME PURPOSES AS HELXINE: FIVE REMEDIES.

Alsine, a plant known as “myosoton” to some, grows in the woods, to which fact it is indebted for its name of “alsine.” It begins to make its appearance at mid-winter, and withers in the middle of summer. When it first puts forth, the leaves bear a strong resemblance to the ears of mice. We shall have occasion, however, to speak of another plant, which may, with much more justice, be called “myosotis.” As for alsine, it would be the same thing as helxine, were it not that it is smaller and not so hairy. It grows in gardens, and upon walls more particularly: when rubbed, it emits a smell like that of cucumber. It is used for abscesses, inflammations, and all those purposes for which helxine is employed; its properties, however, are not so active. It is applied topically, also, to defluxions of the eyes, and to sores upon the generative organs, and ulcerations, with barley meal. The juice is used as an injection for the ears.

Detailed table of contents

CHAP. 9.

THE ANDROSACES: SIX REMEDIES.

The androsaces is a white plant, bitter, without leaves, and bearing arms surmounted with follicles, containing the seed. It grows in the maritime parts of Syria, more particularly. This plant is administered for dropsy, in doses of two drachmæ, pounded or boiled, in either water, wine, or vinegar: it acts most powerfully as a diuretic. It is used also for gout, either taken internally or used as a liniment. The seed is possessed of similar properties.

[Detailed table of contents](#)

CHAP. 10.

ANDROSÆMON OR ASCYRON: SIX REMEDIES.

Androsæmon or, as some persons call it, “ascyron,” is not unlike hypericon, a plant of which we have spoken already: the stems, however, are larger, redder, and lie more closely together. The leaves are of a white colour, and like those of rue in shape; the seed resembles that of the black poppy, and the upper branches, when bruised, emit a red juice the colour of blood: these branches have also a resinous smell.

This plant grows in vineyards, and it is usually in the middle of autumn that it is taken up and hung to dry. Used as a purgative, it is bruised with the seed, and taken in the morning or just after the evening meal, in doses of two drachmæ, in hydromel, wine, or pure water, the draught amounting to one sextarius in all. It carries off bile, and is particularly good for sciatica; but in this last case, caper root must be taken with resin the day after, the dose being one drachma, to be repeated every four days: after being purged, it is the practice for the patient, if in robust health, to take wine, but if in a weak state of body, water. It is employed topically, also, for gout, burns, and wounds, as it tends to arrest the flow of blood.

Detailed table of contents

CHAP. 11.

AMBROSIA, BOTRYS, OR ARTEMISTA: THREE REMEDIES.

Ambrosia is a vague name, which has fluctuated between various plants: there is one, however, which has been more particularly designated by this appellation, a branchy, shrublike plant, with a thin stem, some three palms in height; the root of it is one third shorter, and the leaves, towards the lower part of the stem, resemble those of rue. Its diminutive branches bear a seed which hangs down in clusters, and has a vinous smell: hence it is that by some persons the plant is called “botrys,” while to others it is known as “artemisia.” The people of Cappadocia use it for garlands. It is employed in medicine as a resolvent.

Detailed table of contents

CHAP. 12.

THE ADONIS OR ONONIS: FIVE REMEDIES.

The anonis, by some called “ononis” in preference, is a branchy plant, and similar to fenugreek in appearance, except that it is more shrub-like and more hairy. It has an agreeable smell, and becomes prickly after spring. It is pickled in brine for eating. Applied fresh to ulcers, it cauterizes the margins of them. For the cure of tooth-ache, the root is boiled in oxycrate: taken in drink, with honey, the root expels urinary calculi. For epilepsy, it is administered in oxymel, boiled down to one half.

[Detailed table of contents](#)

CHAP. 13.

THE ANAGYROS OR ACOPON: THREE REMEDIES.

The anagyros, known to some by the name of “aco- pon,” is a shrub-like plant, with an offensive smell, and a blossom like that of the cabbage. The seed grows in small hornlike pods of considerable length, and resembles a kidney in shape; it hardens about the time of harvest. The leaves of this plant are applied to gatherings, and are attached to the person in cases of difficult parturition, care being taken to remove them the moment after delivery. In cases where the extraction of the dead fœtus is attended with difficulty, or where the after-birth or catamenia are retarded, the leaves are taken, in doses of one drachma, in raisin wine. The leaves are administered in the same manner for asthma: they are prescribed also in old wine, for injuries inflicted by the phalangium. The root is employed medicinally as a resolvent and maturative: the seed, chewed, acts as an emetic.

[Detailed table of contents](#)

CHAP. 14.

THE ANONYMOS: TWO REMEDIES.

The anonymos, through not having a name, has at last found one. It is brought from Scythia, and has been highly extolled by Hicesius, a physician of no small repute, as also by Aristogiton. Bruised in water and applied, it is remarkably useful for wounds, and taken in drink it is good for blows upon the chest or mamillæ, as also for spitting of blood: it has been thought, too, that it might be advantageously taken in a potion for wounds. I am of opinion that the additional statement, to the effect that, burnt fresh, it acts as a solder to iron or copper, is wholly fabulous.

[Detailed table of contents](#)

CHAP. 15. (5.)

APARINE, OMPHALOCARPOS, OR PHILANTHROPOS: THREE REMEDIES.

Aparine, otherwise called “omphalocarpos” or “philanthropos,” is a ramose, hairy, plant, with five or six leaves at regular intervals, arranged circularly around the branches. The seed is round, hard, concave, and of a sweetish taste. It grows in cornfields, gardens, and meadows, and, by the aid of its prickly points, adheres to the clothes. The seed is employed to neutralize the venom of serpents, being taken in doses of one drachma, in wine: it is useful also for the bite of the phalangium. The leaves, applied topically, arrest ha- morrhage from wounds. The juice is used as an injection for the ears.

Detailed table of contents

CHAP. 16.

THE ARCTION OR ARCTURUM: FIVE REMEDIES.

The arction is by some called “arcturum” in preference: the leaves of it are like those of verbascum, except that they are more hairy; the stem is long and soft, and the seed resembles that of cummin. It grows in rocky localities, and has a tender root, white and sweet. A decoction of it is made with wine for tooth-ache, being retained for that purpose in the mouth. The plant is taken in drink for sciatica and strangury, and is applied with wine to burns and chilblains, which are fomented also with the root and seed bruised in wine.

[Detailed table of contents](#)

CHAP. 17.

THE ASPLENON OR HEMIONION: TWO REMEDIES.

Some persons call the asplenon by the name of “hemio- nion.” It has numerous leaves, a third of a foot in length, and a slimy root, pierced with holes like that of fern, white, and hairy, It is destitute of stem, flower, and and is found growing upon rocks or sheltered damp walls. The most approved kind is that of Crete. A decoction of the leaves in vinegar, taken in drink for a period of thirty days, will consume the spleen, it is said, the leaves being applied simultaneously. The leaves give relief also in hiccup. This plant should never be given to females, being productive of sterility.

[Detailed table of contents](#)

CHAP. 18.

THE ASCLEPIAS: TWO REMEDIES.

The asclepias has leaves like those of ivy, long branches, and numerous roots, thin, and odoriferous. The flower has a strong offensive smell, and the seed is like that of securidaca: it is found growing in mountainous districts. The roots are used for the cure of griping pains in the bowels, and of stings inflicted by serpents, either taken in drink or applied topically.

[Detailed table of contents](#)

CHAP. 19.

THE ASTER OR BUBONION: THREE REMEDIES.

The aster is called “bubonion” by some, from the circumstance of its being a sovereign remedy for diseases of the groin. It has a diminutive stem with oblong leaves, two or three in number; and at the summit it is surmounted with small radiated heads, like stars. This plant is taken also in drink as an antidote to the venom of serpents: but if required for the cure of inguinal complaints, it is recommended that it should be gathered with the left hand, and attached to the body near the girdle. It is of great service also, worn as an amulet, for sciatica.

Detailed table of contents

CHAP. 20.

ASCYRON AND ASCYROÏDES: THREE REMEDIES.

Ascyron and ascyroïdes are plants similar to one another, and to hypericon as well, except that the plant known as

ascyroïdes” has larger branches, ferulaceous, red all over, and bearing small yellow heads. The seed, enclosed in small calyces, is diminutive, black, and resinous. The tops of the branches, when bruised, stain like blood; for which reason some persons have given it the name of “androsæmon.” The seed is used for the cure of sciatica, being taken in doses of two drachmæ, in one sextarius of hydromel. It relaxes the bowels, and carries off bile: it is applied also to burns.

Detailed table of contents

CHAP. 21.

THE APHACA: THREE REMEDIES.

The aphaca has remarkably diminutive leaves, and is but little taller than the lentil. The pods are of a larger size, and enclose some three or four seeds, of a darker colour, moister, and more diminutive than those of the lentil: it grows in cultivated fields. It is naturally more astringent than the lentil, but in other respects is applied to much the same purposes. The seed, used in a decoction, arrests fluxes of the stomach and bowels.

Detailed table of contents

CHAP. 22.

ALCIBIUM : ONE REMEDY.

I have not found it stated by authors what kind of plant alcibium is; but the root, I find, and the leaves, are pounded and employed, both externally and internally, for injuries inflicted by serpents. When the leaves are used, a handful of them is bruised in three cyathi of undiluted wine: the root is employed in the proportion of three drachmæ to the same quantity of wine.

[Detailed table of contents](#)

CHAP. 23.

ALECTOROSLOPHOS OR CRISTA: TWO REMEDIES.

Alectoroslophos, or crista, as we call it, has numerous leaves resembling a cock's comb, a thin stem, and a black seed enclosed in pods. Boiled with broken beans and honey, it is useful for cough and for films upon the eyes. The seed, too, is sprinkled whole into the eyes, and so far is it from injuring them, that it attracts and collects the filmy matter. When thus used, it changes colour, and from black becomes white, gradually swells, and comes out of itself.

[Detailed table of contents](#)

CHAP. 24. (6.)

ALUM, ALSO CALLED SYMPHYTON PETRÆON: FOURTEEN REMEDIES.

The plant which we call “alum,” and which is known to the Greeks as “symphyton petræon,” is similar to cunila bubula in appearance, having a diminutive leaf and three or four branches springing from the root, with tops like those of thyme. It is a ligneous plant, odoriferous, of a sweet flavour, and provocative of saliva: the root of it is long and red. It grows upon rocks, to which circumstance it is indebted for its additional name of “petræon;” and is extremely useful for affections of the sides and kidneys, griping pains in the bowels, diseases of the chest and lungs, spitting of blood, and eruptions of the fauces. The root is pounded and taken in drink, or else a decoction is made of it in wine; sometimes, also, it is applied externally. Chewed, it allays thirst, and is particularly refreshing to the pulmonary organs. It is employed topically for sprains and contusions, and has a soothing effect upon the intestines.

Cooked upon hot ashes, with the follicules removed, and then beaten up with nine peppercorns and taken in water, it acts astringently upon the bowels. For the cure of wounds it is remarkably efficacious, being possessed of agglutinating properties to such a remarkable degree as to solder pieces of meat together with which it is boiled; to which, in fact, it is indebted for its Greek name. It is used also for the cure of fractured bones.

[Detailed table of contents](#)

CHAP. 25. (7.)

ALGA RUFA OR RED SEA-WEED: ONE REMEDY.

Red sea-weed is useful as an application for the sting of the scorpion.

Detailed table of contents

CHAP. 26.

ACTÆA: ONE REMEDY.

Actæa has leaves with a powerful smell, rough knotted stems, a black seed like that of ivy, and soft berries. It grows in umbrageous, rugged, watery localities; and is used, in doses of one full acetabulum, for female complaints.

[Detailed table of contents](#)

CHAP. 27.

THE AMPELOS AGRIA, OR WILD VINE: FOUR REMEDIES.

Ampelos agria, or wild vine, is the name of a plant with leaves of an ashy colour, as already stated in our description of the cultivated plants, and long, tough twigs of a red hut, like that of the flower which we have mentioned, when speaking of violets, under the name of “flame of Jove.” It bears a seed which resembles the grains of the pomegranate. The root, boiled in three cyathi of water, with the addition of two cyathi of Coan wine, is slightly laxative to the bowels, and is consequently given for dropsy. It is curative also of uterine affections, and of spots upon the face in females. It is found a good plan for patients afflicted with sciatica to use the juice of this plant, bruised, applied topically, with the leaves.

Detailed table of contents

CHAP. 28.

-ABSINTHIUM OR WORMWOOD; FOUR VARIETIES: FORTY-EIGHT REMEDIES.

There are numerous kinds of absinthium; the Santonic, for instance, so called from a city in Gaul, and the Pontic, which comes from Pontus, where the cattle are fattened upon it — a diet which causes them to be destitute of gall. The Pontic wormwood, we may remark, is of the finest quality, superior to that of Italy, and much more bitter; the pith, however, of the Pontic wormwood is sweet. As to its general utility, a plant so commonly found and applied to such numerous uses, people are universally agreed; but with the Romans more particularly it has been always held in the highest esteem, from the fact of its being employed in their religious ceremonials. Thus, for instance, upon the Latin Festival, it is the custom to have a race of four-horsed chariots in the Capital, and for the conqueror to be presented with a draught of wormwood; from the circumstance, no doubt, that our forefathers were of opinion that good health was the most valuable reward they could bestow upon his skill.

This plant is very strengthening to the stomach, and hence it is that wines are flavoured with it, as already stated. A decoction of it in water is also taken, the following being the method employed in preparing it. Six drachmæ of the leaves are boiled, with the branches, in three sextarii of rain water, and the preparation is then left to cool in the open air a day and a night. Salt, too, should be added to it. When old, it is utterly useless. A dilution of wormwood steeped in water is also used, such being the name given to this method of preparing it. This dilution is made by leaving the vessel covered up for three days, any kind of water being used. Pounded wormwood is but rarely employed, and the same with the extracted juice of the seed. In cases, however, where it is extracted, the seed is subjected to pressure as soon as it begins to swell, after which it is soaked for three days in water, if used fresh, and seven, if dry. It is then boiled in a copper vessel, in the proportion of ten heminæ to forty-five sextarii of water, after which it is strained off and boiled gently to the consistency of honey, in the same way as the juice is extracted from the smaller centaury. The juice, however, of wormwood, thus extracted, is bad for the head and stomach; whereas the decoction, on the other hand, is wholesome in the highest degree, as it acts astringently upon the stomach, carries off bile, is a powerful diuretic, has a soothing effect upon the bowels, and assuages pains in the intestines. With the addition of sile, Gallic nard, and a little vinegar, it dispels nausea and flatulency, and expels intestinal worms. It removes qualmishness, promotes the digestion, and, with the addition of rue, pepper, and salt, disperses crudities of the stomach.

The ancients were in the habit of giving wormwood as a purgative, the dose being six drachmæ of the seed with three of salt and one cyathus of

honey, in one sextarius of sea water kept for some time. This preparation, however, is rendered more efficacious by doubling the proportion of salt; the seed, too, must be bruised with the greatest care, as there is considerable difficulty in pounding it. Some authorities have prescribed the dose above mentioned to be given in polenta, with the addition of pennyroyal; while others recommend the leaves to be given to children in a dried fig, to disguise their bitterness. Taken with iris, wormwood acts as a detergent upon the thoracic organs: for jaundice it is used raw, with parsley or adiantum. In cases of flatulency, it is sipped every now and then, warmed in water; for liver complaints it is taken with Gallic nard, and for diseases of the spleen, with vinegar, pap, or figs. Taken in vinegar it neutralizes the bad effects of fungi and of viscus: in wine it is an antidote to the poison of hemlock, and to the bite of the shrew-mouse, and is curative of wounds inflicted by the seadragon and the scorpion. It contributes also very greatly to the improvement of the sight, and is used as an external application, with raisin wine, for defluxions of the eyes, and with honey, for bruises.

The steam of a decoction of wormwood is curative of affections of the ears; and when they are attacked with running sores, a liniment of wormwood bruised with honey is applied. Three or four sprigs of wormwood, with one root of Gallic nard, taken in six cyathi of water, act as a diuretic and as an emmenagogue; indeed, if taken with honey, or employed as a pessary with wool, it has especial virtues as an emmenagogue. In combination with honey and nitre it is useful for quinzy, and an infusion of it in water is good for epinictis. A topical application is made of it for recent wounds, provided always they have not been touched with water: it is employed also for ulcers upon the head. In combination with Cyprian wax or figs, it is highly recommended as a plaster for the iliac regions: it is curative also of prurigo, but it must never be administered in fevers. Taken in drink, it is a preventive of sea sickness; and, worn attached to the body, beneath an apron, it arrests inguinal swellings. The smell of it induces sleep, a similar effect being produced by placing it under the pillow unknown to the party. Kept among clothes it preserves them from worms, and used as a liniment, with oil, or burnt as a fumigation, it has the effect of driving away gnats.

Writing ink, mixed with an infusion of wormwood, effectually protects the writings from the attacks of mice. Ashes of wormwood, mixed with rose unguent, stain the hair black.

[Detailed table of contents](#)

CHAP. 29.

ABSINTHIUM: MARINUM OR SERIPHUM.

There is a sea wormwood also, known as “seriphum” by some, the most esteemed being that of Taposiris in Egypt. Those initiated in the mysteries of Isis carry a branch of it in the hand. It has a narrower leaf than the preceding plant, and is not so bitter; it is injurious to the stomach, has a laxative effect upon the bowels, and expels intestinal worms. It is taken in drink with oil and salt; or else an infusion of it is taken in a pottage made of meal of three-month wheat. When employed as a decoction, a handful is used to one sextarius of water, the mixture being boiled down to one half.

[Detailed table of contents](#)

CHAP. 30. (8.)

THE BALLOTES, MELAMPRASION, OR BLACK LEEK: THREE REMEDIES.

The Greeks give to the ballotes the other name of “melampрасion,” meaning “black leek.” It is a branchy plant, with black angular stems, covered with hairy leaves, larger and darker than those of the leek, and possessed of a powerful smell. The leaves, bruised and applied with salt, are highly efficacious for bites inflicted by dogs: cooked upon hot ashes and applied in a cabbage leaf, they are curative of condylomata. Mixed with honey, this plant acts as a detergent upon sordid ulcers.

[Detailed table of contents](#)

CHAP. 31.

BOTRYS, AMBROSIA, OR ARTEMISIA: ONE REMEDY.

Botrys is a shrublike plant, which has small yellow branches, with the seed growing all round them, and leaves resembling those of endive. It is found upon the banks of running streams, and is used for the cure of hardness of breathing. The people of Cappadocia call this plant “ambrosia,” others again, “artemisia.”

Detailed table of contents

CHAP. 32.

THE BRABYLA: ONE REMEDY.

The brabyla is possessed of astringent properties like those of the quince, but beyond this, authors give no particulars relative to it.

Detailed table of contents

CHAP. 33.

BRYON MARITIMUM: FIVE REMEDIES.

Sea bryon is a plant, no doubt, with leaves like those of the lettuce, of a wrinkled, pursed appearance, and destitute of stem, the leaves arising from a single root: it grows upon rocks more particularly, and shells sunk in the sand. It has desiccative and astringent qualities in a very high degree, properties which render it useful for reducing all kinds of abscesses and inflammations, those attendant upon gout in particular. It is good also for all affections which stand in need of cooling applications.

[Detailed table of contents](#)

CHAP. 34.

THE BUPLEURON: ONE REMEDY.

I find it stated that seed of bupleuron is given for injuries inflicted by serpents; and that the wound is fomented with a decoction of the plant, in combination with leaves of the mulberry or of organum.

Detailed table of contents

CHAP. 35.

THE CATANANCE; ONE OBSERVATION UPON IT. THE CEMOS: ONE
OBSERVATION UPON IT.

The catanance is a Thessalian plant, which it would be a mere loss of time to describe, seeing that it is only used as an ingredient in philtres. In order, however, to expose the follies of the magical art, it may not be out of place to remark that this plant has been selected for the above-named purpose, from the fact that, as it withers, it gradually contracts and assumes the shape of the claws of a dead kite.

For a similar reason we shall give no description of the plant called “cemos.”

Detailed table of contents

CHAP. 36.

THE CALYX: THREE REMEDIES.

Of the calyx there are two kinds. One of these resembles arum, and is found growing in ploughed soils; the proper time for gathering it being before it begins to wither. It is employed for the same purposes as arum; and an infusion of the root is taken as a purgative and as an emmenagogue. The stalks, boiled with the leaves and some pulse, are curative of tenesmus.

[Detailed table of contents](#)

CHAP. 37.

THE CALYX, KNOWN ALSO AS ANCHUSA OR ONOCLIA: TWO REMEDIES.

The other kind of calyx is known by some persons as “anchusa,” and by others as “onoclia.” The leaves are like those of the lettuce, but longer, and with a downy surface. The root is red, and is employed topically, in combination with fine polenta, for the cure of erysipelas: taken internally with white wine, it is good for affections of the liver.

[Detailed table of contents](#)

CHAP. 38.

THE CIRCÆA: THREE REMEDIES.

The circæa resembles the cultivated trychnon in appearance. It has a small swarthy flower, a diminutive seed, like millet, growing in small horn-shaped pods, and a root half a foot in length, generally triple or fourfold, white, odoriferous, and hot in the mouth. It is found growing upon rocks exposed to the sun. An infusion of it is prepared with wine, and administered for pains and affections of the uterus: to make it, three ounces of the pounded root should be steeped in three sextarii of wine a day and a night. This potion is effectual also for bringing away the after-birth. The seed of this plant, taken in wine or hydromel, diminishes the milk in nursing women.

Detailed table of contents

CHAP. 39.

THE CIRSION: ONE REMEDY.

The cirsion is a plant consisting of a diminutive and delicate stem, two cubits in height, of a triangular form, and covered with prickly leaves. The prickles on the leaves are downy, and the leaves themselves resemble those of buglossos in shape, but are smaller, and of a whitish colour. At the summit of the plant there are small purple heads, which fall off in the shape of down. This plant or the root of it, worn as an amulet, it is said, is curative of the pains attendant upon varicose veins.

[Detailed table of contents](#)

CHAP. 40.

THE CRATÆGONON; TWO KINDS OF IT: EIGHT REMEDIES.

The cratægonon is similar to an ear of corn in appearance. It is formed of numerous shoots, springing from a single root, and full of joints. It grows in umbrageous localities, and has a seed like that of millet, with a remarkably acrid taste. If a man and woman, before the evening meal, take three oboli of this seed in three cyathi of water, for forty days consecutively, before the conception of their issue, it will be sure to be of the male sex, they say.

There is another cratægonon, known also as “thelygonos,” and distinguished from the last mentioned plant by the mildness of the taste. Some persons assert that females, if they take the blossom of this plant in drink, will be sure to conceive before the end of forty days. These plants, used in combination with honey, are curative of black ulcers of a chronic nature; they also fill the concavities made by fistulous ulcers with new flesh, and restore such parts of the body as are wasted by atrophy. They act as a detergent upon purulent sores, disperse inflammatory tumours, and alleviate gout and all kind of abscesses, those of the mamillæ in particular.

Under the name of “cratægos” or “cratægon,” Theophrastus speaks of the tree known in Italy as the “aquifolia.”

Detailed table of contents

CHAP. 41.

THE CROCODILEON: TWO REMEDIES.

The crocodileon resembles the black chamæleon in shape: the root is long, of an uniform thickness, and possessed of a pungent smell. It is found growing in sandy soils. Taken in drink, it causes a copious discharge of coagulated blood at the nostrils, and in this way, it is said, diminishes the volume of the spleen.

Detailed table of contents

CHAP. 42.

THE CYNOSORCHIS OR ORCHIS: FOUR REMEDIES.

The cynosorchis, by some called “orchis,” has leaves like those of the olive, soft, three in number, half a foot in length, and lying upon the ground. The root is bulbous, oblong, and divided into two portions, the upper one hard, and the lower one soft. These roots are eaten boiled, like bulbs, and are mostly found growing in vineyards. If males eat the upper part, they will be parents of male issue, they say; and females, if they eat the lower part, of female. In Thessaly, the men take the soft portion in goats’ milk as an aphrodisiac, and the hard part as an antaphrodisiac. Of these parts, the one effectually neutralizes the action of the other.

Detailed table of contents

CHAP. 43.

THE CHRYSOLACHANUM; TWO VARIETIES OF IT: THREE REMEDIES.
COAGULUM: TERAÆ: TWO REMEDIES.

The chrysolachanum grows in pine plantations, and is similar to the lettuce in appearance. It heals wounds of the sinews, if applied without delay. There is another kind of chrysolachanum mentioned, with a golden flower, and a leaf like that of the cabbage: it is boiled and eaten as a laxative vegetable. This plant, worn as an amulet by a patient suffering from jaundice, provided it be always kept in sight, is a cure for that disease, it is said. I art not certain whether this is all that might be said about the chrysolachanum, but, at all events, it is all that I have found respecting it; for it is a very general fault on the part of our more recent herbalists, to confine their account of plants to the mere name, with a very meagre description of the peculiar features of the plant, — just as though, forsooth, they were universally known. Thus, they tell us, for instance, that a plant known as “coagulum terræ,” acts astringently upon the bowels, and that it dispels strangury, taken in water or in wine.

[Detailed table of contents](#)

CHAP. 44.

THE CUCUBALUS, STRUMUS, OR STRYCHNON: SIX REMEDIES.

The leaves of the cucubalus, they tell us, bruised with vinegar, are curative of the stings of serpents and of scorpions. Some persons call this plant by the name of “strumus,” while others give it the Greek name of “strychnon:” its berries are black. The juice of these berries, administered in doses of one cyathus, in two cyathi of honied wine, is curative of lumbago; an infusion of them with rose oil is used for head-ache, and they are employed as an application for scrofulous sores.

[Detailed table of contents](#)

CHAP. 45.

THE CONFERVA: TWO REMEDIES.

The conferva is peculiar to running streams, those of the Alpine regions more particularly; receiving its name from “conferrumino,” to solder together. Properly speaking, it is rather a fresh-water sponge than a moss or a plant, being a dense, porous mass of filaments. I know an instance where a man, who fell to the ground while lopping a tree of considerable height, and broke nearly every bone of his body, was cured by the agency of this plant. The patient’s body was covered all over with conferva, the application being continually sprinkled with water the moment it began to dry, and only removed for the purpose of changing it when the plant gave signs of losing its virtues. It is hardly credible with what rapidity he recovered.

Detailed table of contents

CHAP. 46. (9.)

THE COCCUS CNIDIUS, OR GRAIN OF CNIDOS: TWO REMEDIES.

The Cnidian grain has just the colour of the kermes berry. It is larger than a peppercorn, and has very heating properties: hence it is that when used, it is taken in crumb of bread, that it may not burn the throat in passing downwards. It is a sovereign remedy for hemlock, and arrests looseness of the bowels.

Detailed table of contents

CHAP. 47.

THE DIPSACOS: TWO REMEDIES.

The dipsacos has leaves like those of the lettuce, with prickly tubercles on the middle of the back. The stem of it, two cubits in length, is bristling all over with prickles of a similar nature. The joints of the stem are closely covered with two leaves, which form a concave axil in which a saltish dew-like liquid collects. At the summit of the stem there are small heads covered with prickles: it grows in watery localities.

This plant is used for the cure of chaps of the fundament and of fistula; in which latter case the root is boiled down in wine to the consistency of wax, to allow of its being introduced into the fistula in the form of a salve. It is employed; too, for the cure of all kinds of warts: as a liniment for which, the juice collected in the axils, as above mentioned, is also used by some.

[Detailed table of contents](#)

CHAP. 48.

THE DRYOPTERIS: TWO REMEDIES.

The dryopteris, which resembles fern in appearance, is found growing upon trees; the leaves are of a somewhat sweetish flavour and marked with slight indentations, and the root is hairy. This plant is possessed of caustic properties, and hence the root is pounded and used as a depilatory. In using it the skin is rubbed with it till perspiration is excited, the operation being repeated a second and a third time, care being taken not to remove the perspiration.

[Detailed table of contents](#)

CHAP. 49.

THE DRYOPHONON.

The dryophonon is a similar plant, with thin stems a cubit in length, and surrounded on either side with leaves about as large as the thumb and like those of the oxymyrsine in appearance, only whiter and softer: the blossom is white, and similar to that of the elder. The shoots of it are eaten boiled, and the seed is used as a substitute for pepper.

[Detailed table of contents](#)

CHAP. 50.

THE ELATINE: TWO REMEDIES.

The elatine has leaves like those of the helxine, diminutive, round, and hairy; its branches are small, half a foot in length, five or six in number, and covered with leaves from the root upwards. It grows in corn-fields, and has a rough flavour: hence it is found very useful for defluxions of the eyes, the leaves being beaten up and applied with polenta in a linen pledget. A decoction of this plant with linseed, taken in pottage, is good for dysentery.

[Detailed table of contents](#)

CHAP. 51.

EMPETROS. BY OUR PEOPLE CALLED CALCIFRAGA: FOUR REMEDIES.

Empetros, by the people of our country called “calcifraga,” grows on mountains near the sea, and is generally found upon rocks: the nearer it grows to the sea the salter it is, acting as an evacuant of bile and pituitous secretions. That, on the other hand, which grows at a greater distance and more inland, is of a more bitter flavour. It carries off the aqueous humours of the body, being taken for that purpose in broth of some kind, or else hydromel. When old, it loses its strength; but used fresh, either boiled in water or pounded, it acts as a diuretic, and disperses urinary calculi. Authorities who wish full credence to be given to this asserted property, assure us that pebbles boiled with it will split asunder.

Detailed table of contents

CHAP. 52.

THE EPIPACTIS OR ELLEBORINE: TWO REMEDIES.

The epipactis, called “elleborine” by some, is a diminutive plant with small leaves. Taken in drink, it is extremely useful for diseases of the liver, and as an antidote to poisons.

[Detailed table of contents](#)

CHAP. 53.

THE EPIMEDION: THREE REMEDIES.

The epimedium consists of a stem of moderate size, with ten or twelve leaves like those of ivy: it never flowers, and has a thin, black root, with a powerful smell. It grows in humid soils. This plant also has certain astringent and cooling properties, but females must be on their guard against it. The leaves, beaten up in wine, prevent the bosom from growing too large in young girls.

[Detailed table of contents](#)

CHAP. 54.

THE ENNEAPHYLLON: TWO REMEDIES.

The enneaphyllon has nine long leaves, and is of a caustic nature. It is employed topically, but when used it is wrapped in wool to prevent it from cauterizing further than desirable, for it blisters immediately. For lumbago and sciatica it is of the greatest utility.

[Detailed table of contents](#)

CHAP. 55.

TWO VARIETIES OF FILIX OR FERN, KNOWN TO THE GREEKS AS PTERIS, OR BLACHNON, AND AS THELYPTERIS, OR NYMPHÆ PTERIS: ELEVEN REMEDIES.

Of fern there are two varieties, equally destitute of blossom and of seed. The Greeks give the name of “pteris,” and sometimes “blachnon,” to the kind in which numerous shoots take their rise from a single root, exceeding two cubits even in length, and with a not unpleasant smell: this plant is thought to be the male fern.

The other kind is known to the Greeks as “thelypteris,” and sometimes, “nymphæa pteris:” it has a single stem only, with comparatively few branches, is shorter, softer, and more tufted than the other, and has channelled leaves growing near the root. Swine are fattened upon the roots of either kind. The leaves of both kinds are arranged on either side in the form of wings, whence the Greek name “pteris.” The roots are long, run obliquely, and are of a swarthy colour, more particularly when dried: when wanted for use, they should be dried in the sun. These plants are found growing everywhere, but in cold soils more particularly; they should be taken up, too, at the setting of the Vergiliæ. The root is only used at the end of three years, neither before that period nor after. They act as an expellent of intestinal worms; for tapeworm honey is taken with them, but in other cases sweet wine, for three days.

They are, both of them, extremely detrimental to the stomach, but are laxative to the bowels, carrying off first the bile and then the aqueous humours of the body. When used for tapeworm, it is the best plan to take scammony with them, in equal proportions. For rheumatic defluxions, the root is taken in doses of two oboli, in water, after a day’s abstinence from food, a little honey being taken first. Neither kind must ever be given to females; for in pregnancy they are productive of abortion, and in other cases entail sterility. Powdered fern is sprinkled upon sordid ulcers, as also upon the necks of beasts of burden, when chafed. Fern-leaves kill bugs, and serpents will never harbour among them: hence it is a good plan to strew them in places where the presence of those reptiles is suspected. The very smell, too, of burnt fern will put serpents to flight. Medical men have made this distinction as to ferns; that of Macedonia, they say, is the best, and that of Cassiope the next.

CHAP. 56.

FEMUR BUBULUM, OR OX THIGH.

The name of femur bubulum is given to a plant which is good for the sinews, applied fresh, and beaten up with salt and vinegar.

[Detailed table of contents](#)

CHAP. 57.

GALEOPSIS, GALEOBDOLON, OR GALION: SIX REMEDIES.

Galeopsis, or as some call it, “galeobdolon” or “galion,” is a plant with a stem and leaves like those of the nettle, only smaller; and which, when bruised, emit a powerful smell. The flower is purple, and the plant is found growing everywhere, about hedges and foot-paths. The leaves and stems, bruised in vinegar, and applied topically, are curative of indurations, carcinomata, and scrofulous sores. They disperse also inflammatory tumours and imposthumes of the parotid glands, and it is found a useful plan to foment the parts affected with a decoction of them. Applied with salt, this plant is curative of putrid ulcers and gangrenous sores.

Detailed table of contents

CHAP. 58.

THE GLAUX: ONE REMEDY.

The glaux was known in ancient times as the “eugalacton.” In the leaves it resembles the cytissus and the lentil, only that they are whiter beneath. The branches, five or six in number, are extremely thin, and, springing from the root, creep upon the ground, with small purple blossoms upon them. This plant is found in localities near the sea. It is boiled in a pottage made of similago, to increase the milk: females, however, after taking it, must immediately use the bath.

[Detailed table of contents](#)

CHAP. 59. (10).

GLAUCION: THREE REMEDIES. DIAGLAUCIA: TWO REMEDIES.

Glaucion grows in Syria and Parthia; it is a plant of stunted growth, and thickly covered with leaves, like those of the Poppy in appearance, only smaller and of a more repulsive aspect: it has an offensive smell, and a bitter, astringent taste. The seed, which is of a saffron colour, is put into a vessel coatd with potter's clay, and heated in an oven; when taken out, a juice is extracted, which is known by the same name as the plant. This juice and the leaves, bruised, are used for defluxins of the eyes, which disappear in an instant, under this treatment: an eye-salve, too, is prepared from the juice, known as "diaglaucia," to medical men. The milk, when the secretion of it is stopped, is restored by the agency of this plant, for which purpose it is taken in water.

Detailed table of contents

CHAP. 60.

THE GLYCYSIDE, PÆONIA, OR PENTOROBOS: TWENTY REMEDIES.

The glycy-side, by some called “pæonia” or “pentorobos,” has a stem two cubits in length, accompanied by two or three others, and of a reddish colour, with a bark like that of the laurel. The leaves are similar to those of isatis, but more unctuous, rounder, and more diminutive; the seed is enclosed in capsules, some being red and some black, there being two varieties of the plant. The female plant is generally thought to be the one to the root of which some six or eight bulbs are attached, of an elongated form; those of the male plant being more in number, as it throws out more roots than one, a palm in length, and of a white colour: it has also an astringent taste. The leaves of the female plant smell like myrrh, and lie closer together than those of the male.

Both plants grow in the woods, and they should always be taken up at night, it is said; as it would be dangerous to do so in the day-time, the woodpecker of Mars being sure to attack the eyes of the person so engaged. It is stated also that the person, while taking up the root, runs great risk of being attacked with procidence of the anus: all this, however, I take to be so much fiction, most frivolously invented to puff off their supposed marvellous properties. Both plants are used for various purposes: the red seed, taken in red wine, about fifteen in number, arrest menstruation; while the black seed, taken in the same proportion, in either raisin or other vine, are curative of diseases of the uterus. The root, taken in wine, allays all kinds of pains in the bowels, and acts as a purgative; it cures opisthotony also, jaundice, nephritic diseases, and affections of the bladder. Boiled in wine, it is used for diseases of the trachea and stomach, and acts astringently upon the bowels. It is eaten also by beasts of burden, but when wanted for remedial purposes, four drachmæ are sufficient.

The black seed is useful as a preventive of night-mare, being taken in wine, in number above stated: it is very good, too, to eat this seed, and to apply it externally, for gnawing pains of the stomach. Suppurations are also dispersed, when recent, with the black seed, and when of long standing, with the red: both kinds are very useful, too, for wounds inflicted by serpents, and in cases where children are troubled with calculi, being employed at the crisis when strangury first makes its appearance.

Detailed table of contents

CHAP. 61.

GNAPHALIUM OR CHAMÆZELON: SIX REMEDIES.

Gnaphalium is called “chamæzelon” by some: its white, soft, leaves are used as flock, and, indeed, there is no perceptible difference. This plant is administered in astringent wine, for dysentery: it arrests looseness of the bowels and the catamenia, and is used as an injection for tenesmus. It is employed topically for putrid sores.

Detailed table of contents

CHAP. 62.

THE GALLIDRAGA: ONE REMEDY.

Xenocrates gives the name of “gallidraga” to a plant which resembles the leucacanthus, and grows in the marshes. It is a prickly plant, with a tall, ferulaceous stem, surmounted with a head somewhat similar to an egg in appearance. When this head is growing, in summer, small worms, he says, are generated, which are put away in a box for keeping, and are attached as an amulet, with bread, to the arm on the side on which tooth-ache is felt; indeed it is quite wonderful, he says, how soon the pain is removed. These worms, however, are of no use after the end of a year, or in cases where they have been allowed to touch the ground.

Detailed table of contents

CHAP. 63.

HOLCUS OR ARISTIS.

Holcus is a plant that grows in arid, stony, spots: it has an ear at the end of a fine stem, and looks like barley that has put forth again when cut. Attached to the head or around the arm, it extracts spikes of corn adhering to the flesh; for which reason, some persons give it the name of “aristis.”

[Detailed table of contents](#)

CHAP. 64.

HYOSERIS: ONE REMEDY.

Hyoseris resembles endive in appearance, but is a smaller plant, and rougher to the touch: pounded and applied to wounds, it heals them with remarkable rapidity.

Detailed table of contents

CHAP. 65.

THE HOLOSTEON: THREE REMEDIES.

The holosteon, so called by the Greeks by way of antiphrasis, (in the same way that they give the name of “sweet” to the gall,) is a plant destitute of all hardness, of such extreme fineness as to resemble hairs in appearance, four fingers in length, and very similar to hay-grass. The leaves of it are narrow, and it has a rough flavour: it grows upon elevated spots composed of humus. Taken in wine, it is used for ruptures and convulsions. It has the property, also, of closing wounds; indeed, if applied to pieces of meat it will solder them together.

[Detailed table of contents](#)

CHAP. 66.

THE HIPPOPHÆSTON: EIGHT REMEDIES.

The hippophæston is one of those prickly plants which fullers use in their coppers; it has neither stem nor flower, but only diminutive, empty heads, numerous small leaves of a grass-green colour, and small, soft, white roots. From these roots a juice is extracted in summer, which, taken in doses of three oboli, acts as a purgative; being used for this purpose in cases of epilepsy, fits of trembling, dropsy, vertigo, hardness of breathing, and incipient paralysis.

[Detailed table of contents](#)

CHAP. 67. (11.)

THE HYPOGLOSSA: ONE REMEDY.

The hypoglossa is a plant with leaves like those of the wild myrtle, of a concave form, prickly, and presenting another small leaf within, resembling a tongue in shape. A wreath made of these leaves, placed upon the head, alleviates headache.

[Detailed table of contents](#)

CHAP. 68.

HYPECOÖN.

Hypecoön is a plant found growing in corn-fields, with leaves like those of rue. Its properties are similar to those of juice of poppies.

Detailed table of contents

CHAP. 69.

THE IDÆA HERBA, OR PLANT OF IDA: FOUR REMEDIES.

The Idæan plant has leaves like those of the oxymyrsine; to which leaves a sort of tendril adheres, that bears a flower. This plant arrests diarrhœa, the catamenia, when in excess, and all kinds of hæmorrhage. It is of an astringent and repercussive nature.

Detailed table of contents

CHAP. 70.

THE ISOPYRON OR PHASIOOLON: TWO REMEDIES.

The isopyron is called “phasiolon” by some, from the circumstance that the leaf of it, which resembles that of anise, assumes a spiral form like the tendrils of the phasiolus. At the summit of the stem, it bears small heads full of a seed like that of melanthium. These heads, taken with honey or hydromel, are good for cough and other affections of the chest; they are extremely useful also for liver complaints.

Detailed table of contents

CHAP. 71.

THE LATHYRIS: TWO REMEDIES.

The lathyrus has numerous leaves like those of the lettuce, with numbers of small buds, in which the seed is contained, enclosed in envelopes like that of the caper. When these buds are dry, the seeds, about the size of a peppercorn, are taken out: they are white, sweet, and easily cleansed from the husk. Twenty of them, taken in pure water or in hydromel, are curative of dropsy, and carry off bile. Persons who require a stronger purgative, take them with the husks on. They are apt, however, to be injurious to the stomach; for which reason a plan has been adopted of taking them with fish or else chicken broth.

[Detailed table of contents](#)

CHAP. 72.

THE LEONTOPETALON OR PARDALION: TWO REMEDIES.

The leontopetalon is called “pardalion” by some: it has a leaf like that of the cabbage, and a stem half a foot in height, with numerous lateral branches, and a seed at the extremities of them, enclosed in pods like those of the chick-pea. The root resembles that of rape, and is large and black: it grows in plough lands. The root, taken in wine, neutralizes the venom of all kinds of serpents; indeed, there is nothing known that is more speedily efficacious for that purpose. It is given also for sciatica.

[Detailed table of contents](#)

CHAP. 73.

THE LYCAPSOS: TWO REMEDIES.

The lycapsos has longer and thicker leaves than those of the lettuce, and a long, hairy stem, with numerous offshoots a cubit in length; the flower is diminutive, and of a purple colour; it grows in champaign localities. In combination with barleymeal, it is used as an application for erysipelas: the juice of it, mixed with warm water, is employed as a sudorific, in fevers.

Detailed table of contents

CHAP. 74.

THE LITHOSPERMUM, EXONYCHON, DIOSPYRON, OR HERACLEOS: TWO REMEDIES.

Among all the plants, however, there is none of a more marvellous nature than the lithospermum, sometimes called “exonychon,” “diospyron,” or “heracleos.” It is about five inches in height, with leaves twice the size of those of rue, and small ligneous branches, about the thickness of a rush. It bears close to the leaves a sort of fine beard or spike, standing by itself, on the extremity of which there are small white stones, as round as a pearl, about the size of a chick-pea, and as hard as a pebble. These stones, at the part where they adhere to the stalk, have a small cavity, and contain a seed within.

This plant is found in Italy, no doubt, but that of Crete is the most esteemed. Among all the plants, there is none that I ever contemplated with greater admiration than this; so beauteous is the conformation, that it might be fancied that the hand of an artist had arranged a row of lustrous pearls alternately among the leaves; so exquisite too the nicety in thus making a stone to grow upon a plant! The authorities say that this is a creeping plant, and that it lies upon the ground; but for my own part, I have only seen it when plucked, and not while growing. It is well known that these small stones, taken in doses of one drachma, in white wine, break and expel urinary calculi, and are curative of strangury. Indeed, there is no plant that so instantaneously proclaims, at the mere sight of it, the medicinal purposes for which it was originally intended; the appearance of it, too, is such, that it can be immediately recognized, without the necessity of having recourse to any botanical authority.

Detailed table of contents

CHAP. 75.

LAPIDIS MUSCUS, OR STONE MOSS: ONE REMEDY.

There grows near running streams, a dry, white moss, upon ordinary stones. One of these stones, with the addition of human saliva, is rubbed against another; after which the first stone is used for touching impetigo, the party so doing uttering these words: — φεύγετε χανθαριδες, λύχος ἄγριος αἷμα διώχει.
“Cantharides begone, a wild wolf seeks your blood.”

Detailed table of contents

CHAP. 76.

THE LIMEUM: ONE REMEDY.

Limeum is the name given by the Gauls to a plant, in a preparation of which, known to them as “deer’s poison,” they dip their arrows when hunting. To three modii of salivating mixture they put as much of the plant as is used for poisoning a single arrow; and a mess of it is passed down the throat, in cases where oxen are suffering from disease, due care being taken to keep them fastened to the manger till they have been purged, as they are generally rendered frantic by the dose. In case perspiration supervenes, they are drenched all over with cold water.

[Detailed table of contents](#)

CHAP. 77.

THE LEUCE, MESOLEUCON, OR LEUCAS: THREE REMEDIES.

Leuce, a plant resembling mercurialis, has received its name from the circumstance that a white line runs through the middle of the leaf; for which reason also, some give it the name of “mesoleucon.” The juice of this plant is curative of fistula, and the plant itself, bruised, is good for carcinomata. It is probably the same plant as that called “leucas,” so remarkably efficacious for the venom of all kinds of marine animals. Authors have not given a description of it, beyond telling us that the wild leucas has larger leaves than the other, and has properties more strongly developed: they state also that the seed of the cultivated kind is the more acrid of the two.

Detailed table of contents

CHAP. 78.

THE LEUCOGRAPHIS: FIVE REMEDIES.

I have not found a description given by any writer of the leucographis; a thing I am the more surprised at, as they tell us that it is good for the cure of spitting of blood, taken in doses of three oboli with saffron; as also that it is useful for cœliac affections, applied beaten up in water, and in cases of excessive menstruation. They state also that it enters into the composition of ophthalmic preparations, and that it fills up ulcers on the more tender parts of the body with new flesh.

Detailed table of contents

CHAP. 79. (12.)

THE MEDION: TREE REMEDIES.

The medion has leaves like those of the cultivated seris, a stem three feet in length, and a large, round, purple flower, at its extremity. The seed is diminutive, and the root half a foot in length: it grows upon umbrageous, sheltered rocks. The root, taken in doses of two drachmæ with honey, arrests the catamenia, the electuary being used for some days. The seed, too, is administered in wine for a similar purpose.

[Detailed table of contents](#)

CHAP. 80.

THE MYOSOTA OR MYOSOTIS: THREE REMEDIES.

The myosota or myosotis is a smooth plant, throwing out from a single root numerous hollowed stems, of a somewhat reddish colour; and bearing at the lower extremities swarthy, narrow, oblong leaves, sharp on the back, arranged in pairs at regular distances, and springing from delicate branches attached with axils to the main stems. The flower is blue, and the root, a finger in length, is provided with numerous filaments like hairs. This plant possesses certain septic and ulcerating properties, and hence is used for the cure of fistula of the eye. The Egyptians say that if upon the morning of the twenty-eight day of their month Thoth, a day which generally falls in our month of August, a person rubs himself with the juice of this plant before speaking to any one, he will be sure to have no diseases of the eyes all that year.

Detailed table of contents

CHAP. 81.

TE MYAGROS: ONE REMEDY.

The myagros is a ferulaceous plant, with leaves like those of madder: the seed is of an oily nature-indeed, an oil is extracted from it. Ulcerations of the mouth are cured by rubbing them with the juice of this plant.

Detailed table of contents

CHAP. 82.

THE NYMA: ONE REMEDY.

The plant called “nyma” bears three long leaves, like those of endive: applied to scars, it restores the skin to its natural colour.

[Detailed table of contents](#)

CHAP. 83.

THE NATRIX: ONE REMEDY.

“Natrix” is the name of a plant, the root of which, when taken out of the ground, has just the rank smell of the he-goat. It is used in Picenum for the purpose of keeping away from females what with a singular credulity they call by the name of “Fatui.” For my own part, however, I should think that persons requiring to be treated with such medicaments as these, must be labouring under a sort of mental hallucination.

Detailed table of contents

CHAP. 84.

ODONTITIS: ONE REMEDY.

Odontitis is a sort of hay-grass, which throws out from a single root numerous, small, jointed. stems, of a triangular form and of a swarthy hue. At the joints there are small leaves, somewhat longer than those of the polygonos; and in the axils formed by these leaves is the seed, similar to barley in appearance. It has a purple, diminutive flower, and is found growing in meadows. A handful of the stems, boiled in astringent wine, is used for the cure of tooth-ache, the decoction being retained for some time in the mouth.

[Detailed table of contents](#)

CHAP. 85.

THE OTHONNA: ONE REMEDY.

The othonna is a Syrian plant, resembling rocket in appearance; its leaves are pierced with numerous holes, and its flower resembles that of saffron, for which reason some persons have given it the name of “anemone.” The juice of this plant is employed in ophthalmic preparations; it is slightly pungent, of a warming nature, and astringent as it dries. It acts as a detergent upon cicatrizations, films on the eyes, and all impediments of the sight. Some say that the plant is washed and dried, and then divided into lozenges.

[Detailed table of contents](#)

CHAP. 86.

THE ONOSMA: ONE PROPERTY.

The onosma has leaves some four fingers in length, lying upon the ground, and indented like those of the anchusa: it has neither stem, blossom, nor seed. A pregnant woman, they say, if she eats of this plant, or even walks over it, will be sure to miscarry.

Detailed table of contents

CHAP. 87.

THE ONOPORDON: FIVE REMEDIES.

The onopordon, it is said, has strongly carminative effects upon asses, when they eat of it. It acts as a diuretic and as an emmenagogue, arrests diarrhœa, and disperses abscesses and suppurations.

Detailed table of contents

CHAP. 88.

THE OSYRIS: FOUR REMEDIES.

The osyris bears small, swarthy, flexible branches, covered with dark leaves like those of flax. The seed, which grows upon the branches, is black at first, but afterwards changes its colour and turns red. Cosmetics for females are prepared from these branches. A decoction of the roots, taken in drink, is curative of jaundice. The roots, cut in pieces before the seed ripens, and dried in the sun, act astringently upon the bowels: gathered after the seed has ripened, and boiled in pottage, they are curative of defluxions of the abdomen: they are taken also by themselves, bruised in rain water.

[Detailed table of contents](#)

CHAP. 89.

THE OXYS: TWO REMEDIES.

The oxys is a plant with three leaves; it is given for derangement of the stomach, and patients eat it who are suffering from intestinal hernia.

[Detailed table of contents](#)

CHAP. 90.

THE POLYANTHEMUM OR BATRACHION: THREE REMEDIES.

The polyanthemum, by some persons called “batrachion,” by virtue of its caustic properties has an excoriating effect upon scars, and restores the skin to its proper colour. It heals white morpew also.

Detailed table of contents

CHAP. 91.

THE POLYGONOS, POLYGONATOS, TEUTHALIS, CARCI- NETHRON, CLEMA, OR MYRTOPETALOS, OTHERWISE KNOW AS SANGUINARIA OR ORIOS; FOUR VARIETIES OF IT: FORTY REMEDIES.

The Greeks give the name of “polygonos” to the plant known to us as “sanguinaria.” It is but little elevated above the ground, has leaves like those of rue, and resembles grass in appearance. The juice of it, injected into the nostrils, arrests hæmorrhage: taken with wine, it has a similar effect upon bleeding at any other part of the body, as also spitting of blood. Those who distinguish several kinds of polygonos, make this to be the male plant, and say that it is so called from the large number of seeds, or else from its numerous branches. Some call it “polygonatos,” from the number of its joints, others, again, “teuthalis,” and others, “carcinethron,” “clema,” or “myrtopetalos.”

There are some authorities to be found, however, who say that this is the female plant, and that the male is more diminutive, less swarthy, and more jointed, with a seed protruding beneath all the leaves. However this may be, these plants are of an astringent, cooling nature. The seed is laxative, and, taken in large doses, acts as a diuretic, and arrests defluxions; indeed, if there is no defluxion, it is of no use taking it. For burning heats of the stomach, the leaves are applied topically; and they are used, in the form of a liniment, for pains in the bladder, and for erysipelas. The juice is used as an injection for suppurations of the ears, and by itself, for pains in the eyes. It is administered, also, in fevers, tertian and quartan fevers more particularly, in doses of two cyathi, just before the paroxysms come on; as also in cases of cholera, dysentery, and derangement of the stomach.

There is a third kind, which grows on the mountains, and is known as “orios,” similar to a delicate reed in appearance, and having but a single stem, with numerous joints running into one another; the leaves of it are similar to those of the pitchtree, and the root is never used. This variety, however, is not so efficacious as those already mentioned, and, indeed, is used exclusively for sciatica. A fourth kind is known as the wild polygonos: it is a shrub, almost a tree in fact, with a ligneous root, a red trunk like that of the cedar, and branches resembling those of spartum, a couple of palms in length, and with three or four dark-coloured, knotted joints. This kind, also, is of an astringent nature, and has a flavour like that of the quince. It is either boiled down in water to one third, or else dried and powdered for sprinkling upon ulcerations of the mouth and excoriations: it is chewed, also, for affections of the gums. It arrests the progress of corrosive ulcers and of all sores of a serpiginous nature, or which cicatrize with difficulty, and is particularly useful for ulcerations caused by snow. Herbalists employ it also for quinzy, and use it as a chaplet for head-ache; for defluxions of the eyes, they put it round the neck.

In cases of tertian fever, some persons pull it up with the left hand, and

attach it as an amulet to the body; the same, too, in cases of hæmorrhage. There is no plant that is more generally kept by them in a dry state than the polygonos.

Detailed table of contents

CHAP. 92.

THE PANCRATIUM: TWELVE REMEDIES.

The pancratium is called by some the “little squill,” in preference: it has leaves like those of the white lily, but longer and thicker, and a root composed of a large, red, bulb. The juice of it, taken with meal of fitches, relaxes the bowels, and acts as a detergent upon ulcers: for dropsy, and diseases of the spleen, it is administered with honey. Some persons boil it till the water becomes sweet; the water is then poured off, and the root is pounded and divided into tablets, which are dried in the sun and used for ulcerations of the head, and other affections which require detergents. It is sometimes given for cough, a pinch in three fingers in wine, and, in the form of an electuary, for pains in the side or peripneumony.

It is administered, also, in wine, for sciatica, griping pains in the bowels, and retardations of the catamenia.

[Detailed table of contents](#)

CHAP. 93.

THE PEPLIS, SYCE, MECONION, OR MECON APHRODES: THREE REMEDIES.

The peplis, known by the various names of “syce,” “meconion,” and “mecon aphrodes,” is a shrub-like plant, springing from a single, diminutive, root. The leaves of it resemble those of rue, but are a little larger; the seed, which lies beneath the leaves, is round, and smaller than that of the white poppy. It is ordinarily gathered in vineyards, at harvest-time, and is dried with the seed on, receivers being placed beneath to catch it as it falls. This seed, taken in drink, purges the bowels, and carries off bile and pituitous secretions: one acetabulum, taken in three heminæ of hydromel, is a middling dose. It is sprinkled also upon meat and other articles of food, as a laxative medicine.

Detailed table of contents

CHAP. 94.

THE PERICLYMENOS: FIVE REMEDIES.

The periclymenos is also a shrub-like plant, with two whitish, soft, leaves, arranged at intervals. At the extremity, among the leaves, is the seed, hard, and very difficult to pluck. It grows in ploughed fields and hedges, entwining around every object from which it can gain support. The seed is dried in the shade, pounded, and divided into lozenges. These lozenges are left to dissolve, in three cyathi of white wine, for a period of thirty days, and are given for diseases of the spleen; the volume of which is gradually diminished either by discharges of bloody urine, or else by alvine evacuation, the effects of the medicament being perceptible at the end of ten days. The leaves, boiled, act as a diuretic, and are useful for hardness of breathing. Taken in drink, in manner above- mentioned, they facilitate delivery, and bring away the afterbirth.

[Detailed table of contents](#)

CHAP. 95.

PELECINON: ONE REMEDY.

We have already spoken of peleciton as growing in cornfields, a plant which throws out a number of shoots from thin stems, and has leaves like those of the chick-pea. The seed, which is contained in pods of a curved shape, like diminutive horns and three or four in number, is similar to gith in appearance, bitter, and an excellent stomachic. It is used as an ingredient in antidotes.

Detailed table of contents

CHAP. 96.

POLYGALA: ONE REMEDY.

Polygala is a palm in height, with leaves like those of the lentil at the extremity of the stem. It has an astringent taste; taken in drink, it increases the milk in nursing women.

[Detailed table of contents](#)

CHAP. 97.

POTERION, PHRYNION, OR NEURAS: FOUR REMEDIES.

Poterion, or, as some call it, “phrynion” or “neuras,” throws out numerous branches, is shrivelled and prickly, and covered with a thick down. The leaves of it are small and round; the branches long, soft, thin, and flexible; and the blossom elongated, and of a grass-green colour. The seed is never used, but it has a pungent flavour and a powerful smell: the plant is found growing upon moist, watery, elevations. The roots are two or three in number, some two cubits in length, sinewy, white, and firm. It is dug up in autumn, and the stem yields a juice like gum, when cut. The root is said to be of wonderful efficacy as an application for the cure of wounds, more particularly of the sinews, even when severed. A decoction of it is also taken, with honey, for relaxations of the sinews, and for weakness or wounds of those parts.

Detailed table of contents

CHAP. 98.

THE PHALANGITIS, PHALANGION, OR LEUCACANTHA: FOUR REMEDIES.

The phalangitis is by some called “phalangion,” and by others “leucanthemum,” or, as I find it written in some copies, “leucacantha.” Its branches are diminutive, never less than two in number, and running in contrary directions: the blossom is white, and similar to the flower of the red lily; the seed dark and broad, resembling the half of a lentil, but much thinner; and the root slender and of a grass-green colour. The leaves, blossoms, or seed of this plant are employed for the cure of wounds inflicted by scorpions, serpents, and the phalangium, and for the removal of griping pains in the bowels.

Detailed table of contents

CHAP. 99.

THE PHYTEUMA: ONE PROPERTY.

As for the phyteuma, I think it a mere loss of time to describe it, it being only used as an ingredient in philtres.

Detailed table of contents

CHAP. 100.

THE PHYLLON: ONE PROPERTY.

The Greeks give the name of “phyllon” to a plant which grows among the rocks, in mountainous spots. The female plant is of a more grass-green colour than the other, with a thin stem, a diminutive root, and a round seed, like that of the poppy. This last kind ensures the conception of issue of the same sex; while the male plant, differing only in the seed, which resembles the olive at its first appearance, ensures the conception of male issue. They are both taken in wine.

Detailed table of contents

CHAP. 101.

THE PHELLANDRION: TWO REMEDIES.

The phellandrion grows in marshy spots, and has a leaf like that of parsley: the seed of it is taken in drink for calculi and affections of the bladder.

[Detailed table of contents](#)

CHAP. 102.

THE PHALARIS: TWO REMEDIES.

The phalaris has a long thin stem, like a reed, with a drooping flower at the extremity; the seed is like that of sesame. This plant, too, taken with milk and honey, in wine or vinegar, breaks urinary calculi, and is curative of diseases of the bladder.

[Detailed table of contents](#)

CHAP. 103.

THE POLYRRHIZON: FIVE REMEDIES.

The polyrrhizon has leaves like those of myrtle, and numerous roots. These roots are pounded and administered in wine, for injuries inflicted by serpents: they are useful, also, for cattle.

[Detailed table of contents](#)

CHAP. 104.

THE PROSERPINACA: FIVE REMEDIES.

The proserpinaca, a common plant enough, is an excellent remedy for the sting of the scorpion. Powdered and mixed with brine and oil, in which the mæna has been preserved, it is an excellent cure, they say, for quinzy. It is also stated that, however fatigued a person may be, to the extent even of losing his voice, he will be sure to be refreshed, by putting this plant beneath his tongue; and that if it is eaten, a vomit will be the result, productive of good effects.

Detailed table of contents

CHAP. 105.

RHACOMA: THIRTY-SIX REMEDIES.

Rhacoma is imported from the regions situate beyond Pontus. The root of it is similar to black costus, but smaller and somewhat redder, inodorous, and of a hot, astringent flavour; when pounded, it yields a colour like that of wine, but inclining to saffron. Applied topically, it reduces abscesses and inflammations, and heals wounds: used with raisin wine, it allays defluxions of the eyes; with honey, ecchymosis; and with vinegar, livid marks upon the skin. Reduced to powder, it is sprinkled upon malignant ulcers, and is given internally for spitting of blood, in doses of one drachma, in water. For dysentery and cœliac affections, if unattended with fever, it is administered in wine; but if there is fever, in water. It is pounded more easily when it has been steeped in water the night before. A decoction of it is given, in doses of two drachmæ, for ruptures, convulsions, contusions, and falls with violence.

In cases of pains in the chest, a little pepper and myrrh is added. When the stomach is deranged, it is taken in cold water; and the same in cases of chronic cough, purulent expectorations, liver complaint, affections of the spleen, sciatica, diseases of the kidneys, asthma, and hardness of breathing. Pounded and taken in doses of three oboli, in raisin wine, or used in the form of a decoction, it cures irritations of the trachea: applied with vinegar, it acts as a detergent upon lichens. It is taken in drink, also, for flatulency, cold shiverings, chilly fevers, hiccup, gripings of the bowels, herpetic ulcerations, oppressions of the head, vertigo attended with melancholy, lassitude accompanied with pain, and convulsions.

[Detailed table of contents](#)

CHAP. 106.

THE RESEDA: TWO REMEDIES.

In the vicinity of Ariminum, there is a well-known plant called “reseda:” it disperses abscesses and all kinds of inflammations. Those who employ it for these purposes, add the following words: “Reseda,” allay this disease! knowest thou not, knowest thou not, what chick it is that has torn up these roots? Let it have nor head nor feet!” This formula is repeated thrice, the party spitting on the ground each time.

[Detailed table of contents](#)

CHAP. 107.

THE STŒCHAS: THREE REMEDIES.

The stœchas grows only in the islands of that name. It is an odoriferous plant, with leaves like those of hyssop, and of a bitter taste. Taken in drink, it promotes menstruation, and allays pains in the chest. It forms an ingredient, also, in antidotes.

[Detailed table of contents](#)

CHAP. 108.

THE SOLANUM, BY THE GREEKS CALLED STRYCHNON: TWO REMEDIAL
PROPERTIES.

The solanum, according to Cornelius Celsus, is called “strychnon” by the Greeks; it is possessed of repercussive and refrigerative properties.

Detailed table of contents

CHAP. 109.

SMYRNION: THIRTY-TWO REMEDIES. SINON: TWO REMEDIES.

Smyrnion has a stem like that of parsley, but larger leaves, and growing principally about the young shoots, which are numerous. From the midst of these shoots the leaves make their appearance, unctuous, and bending towards the ground. This plant has a medicinal smell, penetrating to a certain degree, and agreeable: the colour of it is a pale yellow, and the stems bear rounded umbels like those of dill, with a round, black seed, which dries at the beginning of summer. The root, also, is odoriferous, of an acrid, pungent flavour, soft and juicy, black on the outer coat and pale within. The smell of it partakes very much of the nature of that of myrrh, to which, in fact, it owes its name: it grows in localities of a stony nature, or covered with humus. Its medicinal properties are warming and resolvent.

The leaves and root are used as a diuretic and as an emmenagogue; the seed arrests diarrhœa; and the root, applied topically, disperses abscesses and suppurations, provided they are not inveterate, and reduces indurated tumours. It is useful, also, for injuries inflicted by the phalangium and by serpents, taken in wine, with the addition of cachrys, polium, or melissophyllum; the dose, however, must be taken a little at a time only, for otherwise it acts as an emetic, a reason for which it is sometimes administered with rue. The seed or root is curative of cough, hardness of breathing, and diseases of the thoracic organs, spleen, kidneys, and bladder; the root, too, is used for ruptures and convulsions. This plant facilitates delivery, and brings away the afterbirth; it is also given, in combination with crethmos, in wine, for sciatica. It acts as a sudorific and carminative, for which reason it is used to disperse flatulency of the stomach; it promotes, also, the cicatrization of wounds.

A juice is extracted from the root, which is very useful for female complaints, and for affections of the thoracic organs and viscera, possessing, as it does, certain calorific, digestive, and detergent properties. The seed, in particular, is given in drink for dropsy, external applications being made of the juice, and emollient poultices applied of the dried rind of the root. It is used, also, as a seasoning for food, boiled meat in particular, with the addition of honied wine, oil, and garum.

Sinon, a plant with a flavour very like that of pepper, promotes the digestion, and is highly efficacious for pains in the stomach.

CHAP. 110.

TELEPHION: FOUR REMEDIES.

Telephion resembles purslain in the stem and leaves. From the root of it there spring seven or eight small branches, covered with thick, fleshy leaves; it grows in cultivated spots, and among vines in particular. It is used as an application for freckles, being removed as soon as dry; it is employed, also, for white morpew, being applied some six hours each night or day, and the treatment continued for about three months: after removing it, barley-meal should be applied. Telephion is healing, also, for wounds and fistulas.

[Detailed table of contents](#)

CHAP. 11.

THE TRICHOMANES: FIVE REMEDIES.

The trichomanes is a plant that resembles the adiantum, except that it is more slender and of a darker colour; the leaves of it, which are similar to those of the lentil, lie close together, on opposite sides, and have a bitter taste. A decoction of this plant, taken in white wine, with the addition of wild cummin, is curative of strangury. Bruised and applied to the head, it prevents the hair from falling off, and, where it has come off, restores it: pounded and applied with oil, it effects the cure of alopecia. The mere taste of it is provocative of sneezing.

[Detailed table of contents](#)

CHAP. 112.

THE THALICTRUM: ONE REMEDY.

The thalictrum has leaves like those of coriander, only somewhat more unctuous, and a stem resembling that of the poppy. It is found growing everywhere, in champaign localities more particularly. The leaves, applied with honey, heal ulcers.

Detailed table of contents

CHAP. 113.

THLASPI AND PERSICON NAPY: FOUR REMEDIES.

Of thlaspi there are two kinds; the first of which has narrow leaves, about a finger in length and breadth, turned to wards the ground, and divided at the point. It has a slender stern, half a foot in length, and not wholly destitute of branches; the seed, enclosed in a crescent-shaped capsule, is similar to a lentil in shape, except that it has a jagged appearance, to which, in fact, it owes its name; the flower is white, and the plant is found near footpaths and in hedges. The seed, which has an acrid flavour, carries off bile and pituitous secretions, by vomit and by alvine evacuation, the proper dose being one acetabulum. It is used, also, for sciatica, in the form of an injection, this treatment being persevered in until it has induced a discharge of blood: it acts also as an emmenagogue, but is fatal to the fœtus.

The other thlaspi, known by some as “Persicon napy,” has broad leaves and large roots, and is also very useful as an injection for sciatica. Both plants are very serviceable for inguinal complaints; it being recommended that the person who gathers them should mention that he is taking them for diseases of the groin, for abscesses of all kinds, and for wounds, and that he should pluck them with one hand only.

Detailed table of contents

CHAP. 114.

THE TRACHINIA: ONE PROPERTY.

What sort of plant the trachinia is, the authorities do not state. I think that the assurance given by Democritus must be false: for it would be nothing less than a prodigy, for a plant, attached as an amulet, to consume the spleen in so short a time as three days.

[Detailed table of contents](#)

CHAP. 115.

THE TRAGONIS OR TRAGION: FOUR REMEDIES.

The tragonis, or tragion, grows nowhere but in the maritime districts of the Isle of Crete; it resembles the juniper in the seed, leaf, and branches. Its milky juice, which thickens in the form of a gum, or its seed, taken in drink, expels pointed weapons from the flesh. The plant, too, is pounded fresh and applied as a liniment with wine, or, dried and powdered, with honey. It increases the milk in nursing women, and is a sovereign remedy for diseases of the mamillæ.

[Detailed table of contents](#)

CHAP. 116.

THE TRAGOS OR SCORPION: FOUR REMEDIES.

There is another plant also, called “tragos,” or “scorpion” by some, half a foot in height, branchy, destitute of leaves, and bearing diminutive red clusters, with a seed like that of wheat, but pointed at the extremity: this too grows in maritime localities. Ten or twelve tops of the branches, bruised and taken in wine, are remedial in cases of cœliac affections, dysentery, spitting of blood, and excessive menstruation.

Detailed table of contents

CHAP. 117.

THE TRAGOPOGON OR COME.

There is the tragopogon, also, by some called “come;” a plant with a small stem, leaves like those of saffron, an elongated, sweet, root, and a large, swarthy calyx at the extremity of the stem. It grows in rugged soils, and is never used.

Detailed table of contents

CHAP. 118.

THE AGES OF PLANTS.

Such, then, is all that I have hitherto been enabled to learn or discover, worthy of mention, relative to plants. At the close of this subject, it seems to me that it will not be out of place to remind the reader, that the properties of plants vary according to their age. It is elaterium, as already stated, that preserves its properties the longest of all. The black chamæleon retains its virtues forty years, centaury not more than twelve, peucedanum and aristolochia six, and the wild vine one year — that is to say, if they are kept in the shade. I would remark, also, that beyond those animals which breed within the plants, there are none that attack the roots of any of those which have been mentioned by me; with the exception, indeed, of the sphondyle, a kind of creeping insect, which infests them all.

Detailed table of contents

CHAP. 119.

HOW THE GREATEST EFFICACY IN PLANTS MAY BE ENSURED.

It is also an undoubted truth, that the virtues and properties of all roots are more feebly developed, when the fruit has been allowed to ripen; and that it is the same with the seed, when incisions have been previously made in the root, for the extraction of the juice. The efficacy, too, of all plants is impaired by making habitual use of them; and these substances, if employed daily, lose equally their good or bad properties, when required to be effectual. All plants, too, have more powerful properties, when grown in soils that are cold and exposed to the north-eastern blasts, or in dry localities.

Detailed table of contents

CHAP. 120.

MALADIES PECULIAR TO VARIOUS NATIONS.

There are certain differences, also, by no means inconsiderable, in the predispositions of the various nations of the earth. I have been informed, for instance, that the people of Egypt, Arabia, Syria, and Cilicia, are subject to tapeworm and mawworm, while those of Thracia and Phrygia, on the other hand, are totally exempt from them. This, however, is less surprising than the fact that, although Attica and Bœotia are adjoining territories, the Thebans are troubled with these inflictions, while among the people of Athens they are unknown.

Considerations of this description lead me now to turn my attention to the nature of the animated beings themselves, and the medicinal properties which are inborn in them, the most assured remedies, perhaps, for all diseases.

For Nature, in fact, that parent of all things, has produced no animated being for the purpose solely of eating; she has willed that it should be born to satisfy the wants of others, and in its very vitals has implanted medicaments conducive to health. While she has implanted them in mute and inanimate objects even, she has equally willed that these, the most invaluable aids of life, should be also derived from the life of another — a subject for contemplation, marvellous in the highest degree!

SUMMARY. — Remedies, narratives, and observations, six hundred and two.

ROMAN AUTHORS QUOTED. — Caius Valgius, Pompeius Lenæus, Sextius Niger who wrote in Greek, Julius Bassus who wrote in Greek, Antonius Castor, Cornelius Celsus.

FOREIGN AUTHORS QUOTED. — Theophrastus, Apollodorus, Democritus, Aristogiton, Orpheus, Pythagoras, Mago, Menander who wrote the “Biochresta,” Nicander.

MEDICAL AUTHORS QUOTED. — Mnesitheus, Timaristus, Simus, Hippocrates, Chrysippus, Diocles, Ophelion, Heraclides, Hicesius, Dionysius, Apollodorus of Citium, Apollodorus of Tarentum, Praxagoras, Plistonicus, Medius, Dieuches, Cleophantus, Philistion, Asclepiades, Crateuas, Petronius Diodotus, Iollas, Erasistratus, Diagoras, Andreas, Mnesides, Epicharmus, Damion, Tlepolemus, Metrodorus, Solo, Lycus, Olympias of Thebes, Philinus, Petrichus, Micton, Glaucias, Xenocrates.

BOOK XXVIII. REMEDIES DERIVED FROM LIVING CREATURES.

Detailed table of contents

CHAP. 1. (1.)

INTRODUCTION.

WE should have now concluded our description of the various things that are produced between the heavens and the earth, and it would have only remained for us to speak of the substances that are dug out of the ground itself; did not our exposition of the remedies derived from plants and shrubs necessarily lead us into a digression upon the medicinal properties which have been discovered, to a still greater extent, in those living creatures themselves which are thus indebted [to other objects] for the cure of their respective maladies. For ought we, after describing the plants, the forms of the various flowers, and so many objects rare and difficult to be found — ought we to pass in silence the resources which exist in man himself for the benefit of man, and the other remedies to be derived from the creatures that live among us — and this more particularly, seeing that life itself is nothing short of a punishment, unless it is exempt from pains and maladies? Assuredly not; and even though I may incur the risk of being tedious, I shall exert all my energies on the subject, it being my fixed determination to pay less regard to what may be amusing, than to what may prove practically useful to mankind.

Nay, even more than this, my researches will extend to the usages of foreign countries, and to the customs of barbarous nations, subjects upon which I shall have to appeal to the good faith of other authors; though at the same time I have made it my object to select no facts but such as are established by pretty nearly uniform testimony, and to pay more attention to scrupulous exactness than to copiousness of diction.

It is highly necessary, however, to advertise the reader, that whereas I have already described the natures of the various animals, and the discoveries due to them respectively — for, in fact, they have been no less serviceable in former times in discovering remedies, than they are at the present day in providing us with them — it is my present intention to confine myself to the remedial properties which are found in the animal world, a subject which has not been altogether lost sight of in the former portion of this work. These additional details therefore, though of a different nature, must still be read in connexion with those which precede.

Detailed table of contents

CHAP. 2.

REMEDIES DERIVED FROM MAN.

We will begin then with man, and our first enquires will be into the resources which he provides for himself-a subject replete with boundless difficulties at the very outset.

Epileptic patients are in the habit of drinking the blood even of gladiators, draughts teeming with life, as it were; a thing that, when we see it done by the wild beasts even, upon the same arena, inspires us with horror at the spectacle! And yet these persons, forsooth, consider it a most effectual cure for their disease, to quaff the warm, breathing, blood from man himself, and, as they apply their mouth to the wound, to draw forth his very life; and this, though it is regarded as an act of impiety to apply the human lips to the wound even of a wild beast! Others there are, again, who make the marrow of the leg-bones, and the brains of infants, the objects of their research!

Among the Greek writers, too, there are not a few who have enlarged upon the distinctive flavours of each one of the viscera and members of the human body, pursuing their researches to the very parings of the nails! as though, forsooth, it could possibly be accounted the pursuit of health for man to make himself a wild beast, and so deserve to contract disease from the very remedies he adopts for avoiding it. Most righteously, by Hercules! if such attempts are all in vain, is he disappointed of his cure! To examine human entrails is deemed an act of impiety; what then must it be to devour them?

Say, Osthanes, who was it that first devised these practices; for it is thee that I accuse, thou uprooter of all human laws, thou inventor of these monstrosities; devised, no doubt, with the view that mankind might not forget thy name! Who was it that first thought of devouring each member of the human body? By what conjectural motives was he induced? What can possibly have been the origin of such a system of medicine as this? Who was it that thus made the very poisons less baneful than the antidotes prescribed for them? Granted that barbarous and outlandish tribes first devised such practices, must the men of Greece, too, adopt these as arts of their own?

We read, for instance, in the memoirs of Democritus, still extant, that for some diseases, the skull of a malefactor is most efficacious, while for the treatment of others, that of one who has been a friend or guest is required. Apollonius, again, informs us in his writings, that the most effectual remedy for tooth-ache is to scarify the gums with the tooth of a man who has died a violent death; and, according to Miletus, human gall is a cure for cataract. For epilepsy, Artemon has prescribed water drawn from a spring in the night, and drunk from the skull of a man who has been slain, and whose body remains unburnt. From the skull, too, of a man who had been hanged, Antæus made pills that were to be an antidote to the bite of; mad dog. Even more than this,

man has resorted to similar remedies for the cure of four-footed beasts even — for tympanitis in oxen, for instance, the horns have been perforated, and human bones inserted; and when swine have been found to be diseased, fine wheat has been given them which has lain for a night in the spot where a human being has been slain or burnt!

Far from us, far too from our writings, be such prescriptions as these! It will be for us to describe remedies only, and not abominations; cases, for instance, in which the milk of a nursing woman may have a curative effect, cases where the human spittle may be useful, or the contact of the human body, and other instances of a similar nature. We do not look upon life as so essentially desirable that it must be prolonged at any cost, be it what it may — and you, who are of that opinion, be assured, whoever you may be, that you will die none the less, even though you shall have lived in the midst of obscenities or abominations!

Let each then reckon this as one great solace to his mind, that of all the blessings which Nature has bestowed on man, there is none greater than the death which comes at a seasonable hour; and that the very best feature in connexion with it is, that every person has it in his own power to procure it for himself.

[Detailed table of contents](#)

CHAP. 3. (2.)

WHETHER WORDS ARE POSSESSED OF ANY HEALING EFFICACY.

In reference to the remedies derived from man, there arises first of all one question, of the greatest importance and always attended with the same uncertainty, whether words, charms, and incantations, are of any efficacy or not? For if such is the case, it will be only proper to ascribe this efficacy to man himself; though the wisest of our fellow-men, I should remark, taken individually, refuse to place the slightest faith in these opinions. And yet, in our every-day life, we practically show, each passing hour, that we do entertain this belief, though at the moment we are not sensible of it. Thus, for instance, it is a general belief that without a certain form of prayer it would be useless to immolate a victim, and that, with such an informality, the gods would be consulted to little purpose. And then besides, there are different forms of address to the deities, one form for entreating, another form for averting their ire, and another for commendation.

We see too, how that our supreme magistrates use certain formulæ for their prayers: that not a single word may be omitted or pronounced out of its place, it is the duty of one person to precede the dignitary by reading the formula before him from a written ritual, of another, to keep watch upon every word, and of a third to see that silence is not ominously broken; while a musician, in the meantime, is performing on the flute to prevent any other words being heard. Indeed, there are memorable instances recorded in our Annals, of cases where either the sacrifice has been interrupted, and so blemished, by imprecations, or a mistake has been made in the utterance of the prayer; the result being that the lobe of the liver or the heart has disappeared in a moment, or has been doubled, while the victim stood before the altar. There is still in existence a most remarkable testimony, in the formula which the Decii, father and son, pronounced on the occasions when they devoted themselves. There is also preserved the prayer uttered by the Vestal Tuccia, when, upon being accused of incest, she carried water in a sieve — an event which took place in the year of the City 609. Our own age even has seen a man and a woman buried alive in the Ox Market, Greeks by birth, or else natives of some other country with which we were at war at the time. The prayer used upon the occasion of this ceremonial, and which is usually pronounced first by the Master of the College of the Quindecimviri, if read by a person, must assuredly force him to admit the potency of formulæ; when it is recollected that it has been proved to be effectual by the experience of eight hundred and thirty years.

At the present day, too, it is a general belief, that our Vestal virgins have the power, by uttering a certain prayer, to arrest the flight of runaway slaves, and to rivet them to the spot, provided they have not gone beyond the

precincts of the City. If then these opinions be once received as truth, and if it be admitted that the gods do listen to certain prayers, or are influenced by set forms of words, we are bound to conclude in the affirmative upon the whole question. Our ancestors, no doubt, always entertained such a belief, and have even assured us, a thing by far the most difficult of all, that it is possible by such means to bring down lightning from heaven, as already mentioned on a more appropriate occasion.

Detailed table of contents

CHAP. 4.

THAT PRODIGIES AND PORTENTS MAY BE CONFIRMED, OR MADE OF NO EFFECT.

L. Piso informs us, in the first Book of his Annals, that King Tullus Hostilius, while attempting, in accordance with the books of Numa, to summon Jupiter from heaven by means of a sacrifice similar to that employed by him, was struck by lightning in consequence of his omission to follow certain forms with due exactness. Many other authors, too, have attested, that by the power of words a change has been effected in destinies and portents of the greatest importance. While they were digging on the Tarpeian Hill for the foundations of a temple, a human head was found; upon which deputies were sent to Olenus Calenus, the most celebrated diviner of Etruria. He, foreseeing the glory and success which attached to such a presage as this, attempted, by putting a question to them, to transfer the benefit of it to his own nation. First describing, on the ground before him, the outline of a temple with his staff—“Is it so, Romans, as you say?” said he; “here then must be the temple of Jupiter, all good and all powerful; it is here that we have found the head” — and the constant asseveration of the Annals is, that the destiny of the Roman empire would have been assuredly transferred to Etruria, had not the deputies, forewarned by the son of the diviner, made answer— “No, not here exactly, but at Rome, we say, the head was found.”

It is related also that the same was the case when a certain four-horse chariot, made of clay, and intended for the roof of the same temple, had considerably increased while in the furnace; and that on this occasion, in a similar manner, the destinies of Rome were saved. Let these instances suffice then to show, that the virtues of presages lie in our own hands, and that they are valuable in each instance according as they are received. At all events, it is a principle in the doctrine of the augurs, that neither imprecations nor auspices of any kind have any effect upon those who, when entering upon an undertaking, declare that they will pay no attention whatever to them; a greater instance than which, of the indulgent disposition of the gods towards us, cannot be found.

And then besides, in the laws themselves of the Twelve Tables, do we not read the following words— “Whosoever shall have enchanted the harvest,” and in another place, “Whosoever shall have used pernicious incantations”? Verrius Flaccus cites authors whom he deems worthy of credit, to show that on the occasion of a siege, it was the usage, the first thing of all, for the Roman priests to summon forth the tutelary divinity of that particular town, and to promise him the same rites, or even a more extended worship, at Rome; and at the present day even, this ritual still forms part of the discipline of our pontiffs. Hence it is, no doubt, that the name of the tutelary deity of Rome has been so strictly kept concealed, lest any of our enemies should act in a similar

manner. There is no one, too, who does not dread being spell-bound by means of evil imprecations; and hence the practice, after eating eggs or snails, of immediately breaking the shells, or piercing them with the spoon. Hence, too, those love-sick imitations of enchantments which we find described by Theocritus among the Greeks, and by Catullus, and more recently, Virgil, among our own writers. Many persons are fully persuaded that articles of pottery may be broken by a similar agency; and not a few are of opinion even that serpents can counteract incantations, and that this is the only kind of intelligence they possess — so much so, in fact, that by the agency of the magic spells of the Marsi, they may be attracted to one spot, even when asleep in the middle of the night. Some people go so far, too, as to write certain words on the walls of houses, deprecatory of accident by fire.

But it is not easy to say whether the outlandish and unpronounceable words that are thus employed, or the Latin expressions that are used at random, and which must appear ridiculous to our judgment, tend the most strongly to stagger our belief-seeing that the human imagination is always conceiving something of the infinite, something deserving of the notice of the divinity, or indeed, to speak more correctly, something that must command his intervention perforce. Homer tells us that Ulysses arrested the flow of blood from a wound in the thigh, by repeating a charm; and Theophrastus says that sciatica may be cured by similar means. Cato has preserved a formula for the cure of sprains, and M. Varro for that of gout. The Dictator Cæsar, they say, having on one occasion accidentally had a fall in his chariot, was always in the habit, immediately upon taking his seat, of thrice repeating a certain formula, with the view of ensuring safety upon the journey; a thing that, to my own knowledge, is done by many persons at the present day.

CHAP. 5.

A DESCRIPTION OF VARIOUS USAGES.

I would appeal, too, for confirmation on this subject, to the intimate experience of each individual. Why, in fact, upon the first day of the new year, do we accost one another with prayers for good fortune, and, for luck's sake, wish each other a happy new year? Why, too, upon the occasion of public lustrations, do we select persons with lucky names, to lead the victims? Why, to counteract fascinations, do we Romans observe a peculiar form of adoration, in invoking the Nemesis of the Greeks; whose statue, for this reason, has been placed in the Capitol at Rome, although the goddess herself possesses no Latin name? Why, when we make mention of the dead, do we protest that we have no wish to impeach their good name? Why is it that we entertain the belief that for every purpose odd numbers are the most effectual; — a thing that is particularly observed with reference to the critical days in fevers? Why is it that, when gathering the earliest fruit, apples, on pears, as the case may be, we make a point of saying

“This fruit is old, may other fruit be sent us that is new?” Why is it that we salute a person when he sneezes, an observance which Tiberius Cæsar, they say, the most unsociable of men, as we all know, used to exact, when riding in his chariot even? Some there are, too, who think it a point religiously to be observed to mention the name as well of the person whom they salute.

And then, besides, it is a notion universally received, that absent persons have warning that others are speaking of them, by the tingling of the ears. Attalus assures us, that if a person, the moment he sees a scorpion, says “Duo,” the reptile will stop short, and forbear to sting. And now that I am speaking of the scorpion, I recall to mind that in Africa no one ever undertakes any matter without prefacing with the word “Africa;” while in other countries, before an enterprise is commenced, it is the practice to adjure the gods that they will manifest their good will.

In addition to this, it is very clear that there are some religious observances, unaccompanied by speech, which are considered to be productive of certain effects. Thus, when we are at table, for instance, it is the universal practice, we see, to take the ring from off the finger. Another person, again, will take some spittle from his mouth and place it with his finger behind the ear, to propitiate and modify disquietude of mind. When we wish to signify applause, we have a proverb even which tells us we should press the thumbs. When paying adoration, we kiss the right hand, and turn the whole body to the right: while the people of the Gallic provinces, on the contrary, turn to the left, and believe that they show mere devoutness by so doing. To salute summer lightning with clapping of the hands, is the universal practice with all nations. If, when eating, we happen to make mention of a fire that has happened, we

avert the inauspicious omen by pouring water beneath the table. To sweep the floor at the moment that a person is rising from table, or to remove the table or tray, as the case may be, while a guest is drinking, is looked upon as a most unfortunate presage. There is a treatise, written by Servius Sulpicius, a man of the highest rank, in which reasons are given why we should never leave the table we are eating at; for in his day it was not yet the practice to reckon more tables than guests at an entertainment. Where a person has sneezed, it is considered highly ominous for the dish or table to be brought back again, and not a taste thereof to be taken, after doing so; the same, too, where a person at table eats nothing at all.

These usages have been established by persons who entertained a belief that the gods are ever present, in all our affairs and at all hours, and who have therefore found the means of appeasing them by our vices even. It has been remarked, too, that there is never a dead silence on a sudden among the guests at table, except when there is an even number present; when this happens, too, it is a sign that the good name and repute of every individual present is in peril. In former times, when food fell from the hand of a guest, it was the custom to return it by placing it on the table, and it was forbidden to blow upon it, for the purpose of cleansing it. Auguries, too, have been derived from the words or thoughts of a person at the moment such an accident befalls him; and it is looked upon as one of the most dreadful of presages, if this should happen to a pontiff, while celebrating the feast of Dis. The proper expiation in such a case is, to have the morsel replaced on table, and then burnt in honour of the Lar. Medicines, it is said, will prove ineffectual, if they happen to have been placed on a table before they are administered. It is religiously believed by many, that it is ominous in a pecuniary point of view, for a person to pare his nails without speaking, on the market days at Rome, or to begin at the forefinger in doing so: it is thought, too, to be a preventive of baldness and of head-ache, to cut the hair on the seventeenth and twenty-ninth days of the moon.

A rural law observed in most of the farms of Italy, forbids women to twirl their distaffs, or even to carry them uncovered, while walking in the public roads; it being a thing so prejudicial to all hopes and anticipations, those of a good harvest in particular. It is not so long ago, that M. Servilius Nonianus, the principal citizen at Rome, being apprehensive of ophthalmia, had a paper, with the two Greek letters P and A written upon it, wrapped in linen and attached to his neck, before he would venture to name the malady, and before any other person had spoken to him about it. Mucianus, too, who was thrice consul, following a similar observance, carried about him a living fly, wrapped in a piece of white linen; and it was strongly asserted, by both of them, that to the use of these expedients they owed their preservation from ophthalmia. There are in existence, also, certain charms against hail-storms, diseases of various kinds, and burns, some of which have been proved, by actual experience, to be effectual; but so great is the diversity of opinion upon

them, that I am precluded by a feeling of extreme diffidence from entering into further particulars, and must therefore leave each to form his own conclusions as he may feel inclined.

CHAP. 6. (3.)

TWO HUNDRED AND TWENTY-SIX OBSERVATIONS ON REMEDIES DERIVED FROM MAN. EIGHT REMEDIES DERIVED, FROM CHILDREN.

We have already, when speaking of the singular peculiarities of various nations, made mention of certain men of a monstrous nature, whose gaze is endowed with powers of fascination; and we have also described properties belonging to numerous animals, which it would be superfluous here to repeat. In some men, the whole of the body is endowed with remarkable properties, as in those families, for instance, which are a terror to serpents; it being in their power to cure persons when stung, either by the touch or by a slight suction of the wound. To this class belong the Psylli, the Marsi, and the people called "Ophiogenes," in the Isle of Cyprus. One Euagon, a member of this family, while attending upon a deputation at Rome, was thrown by way of experiment, by order of the consuls, into a large vessel filled with serpents; upon which, to the astonishment of all, they licked his body all over with their tongues. One peculiarity of this family — if indeed it is still in existence — is the strong offensive smell which proceeds from their body in the spring; their sweat, too, no less than their spittle, was possessed of remedial virtues. The people who are born at Tentyris, an island in the river Nilus, are so formidable to the crocodiles there, that their voice even is sufficient to put them to flight. The presence even, it is well known, of all these different races, will suffice for the cure of injuries inflicted by the animals to which they respectively have an antipathy; just in the same way that wounds are irritated by the approach of persons who have been stung by a serpent at some former time, or bitten by a dog. Such persons, too, by their presence, will cause the eggs upon which a hen is sitting to be addled, and will make pregnant cattle cast their young and miscarry; for, in fact, so much of the venom remains in their body, that, from being poisoned themselves, they become poisonous to other creatures. The proper remedy in such case is first to make them wash their hands, and then to sprinkle with the water the patient who is under medical treatment. When, again, persons have been once stung by a scorpion they will never afterwards be attacked by hornets, wasps, or bees: a fact at which a person will be the less surprised when he learns that a garment which has been worn at a funeral will never be touched by moths; that it is hardly possible to draw serpents from their holes except by using the left hand; and that, of the discoveries made by Pythagoras, one of the most unerring, is the fact, that in the name given to infants, an odd number of vowels is portentous of lameness, loss of eyesight, or similar accidents, on the right side of the body, and an even number of vowels of the like infirmities on the left.

(4.) It is said, that if a person takes a stone or other missile which has slain three living creatures, a man, a boar, and a bear, at three blows, and throws it over the roof of a house in which there is a pregnant woman, her delivery,

however difficult, will be instantly accelerated thereby. In such a case, too, a successful result will be rendered all the more probable, if a light infantry lance is used, which has been drawn from a man's body without touching the earth; indeed, if it is brought into the house it will be productive of a similar result. In the same way, too, we find it stated in the writings of Orpheus and Archelaiis, that arrows, drawn from a human body without being allowed to touch the ground, and placed beneath the bed, will have all the effect of a philtre; and, what is even more than this, that it is a cure for epilepsy if the patient eats the flesh of it wild beast killed with an iron weapon with which a human being has been slain.

Some individuals, too, are possessed of medicinal properties in certain parts of the body; the thumb of King Pyrrhus, for instance, as already mentioned. At Elis, there used to be shown one of the ribs of Pelops, which, it was generally asserted, was made of ivory. At the present day even, there are many persons, who from religious motives will never clip the hair growing upon a mole on the face.

Detailed table of contents

CHAP. 7.

PROPERTIES OF THE HUMAN SPITTLE.

But it is the fasting spittle of a human being, that is, as already stated by us, the sovereign preservative against the poison of serpents; while, at the same time, our daily experience may recognize its efficacy and utility, in many other respects. We are in the habit of spitting, for instance, as a preservative from epilepsy, or in other words, we repel contagion thereby: in a similar manner, too, we repel fascinations, and the evil presages attendant upon meeting a person who is lame in the right leg. We ask pardon of the gods, by spitting in the lap, for entertaining some too presumptuous hope or expectation. On the same principle, it is the practice in all cases where medicine is employed, to spit three times on the ground, and to conjure the malady as often; the object being, to aid the operation of the remedy employed. It is usual, too, to mark a boil, when it first makes its appearance, three times with fasting spittle. What we are going to say is marvellous, but it may easily be tested by experiment: if a person repents of a blow given to another, either by hand or with a missile, he has nothing to do but to spit at once into the palm of the hand which has inflicted the blow, and all feelings of resentment will be instantly alleviated in the person struck. This, too, is often verified in the case of a beast of burden, when brought on its haunches with blows; for upon this remedy being adopted, the animal will immediately step out and mend its pace. Some persons, however, before making an effort, spit into the hand in manner above stated, in order to make the blow more heavy.

We may well believe, then, that lichens and leprous spots may be removed by a constant application of fasting spittle; that ophthalmia may be cured by anointing, as it were, the eyes every morning with fasting spittle; that carcinomata may be effectually treated, by kneading the root of the plant known as “apple of the earth,” with human spittle; that crick in the neck may be got rid of by carrying fasting spittle to the right knee with the right hand, and to the left knee with the left; and that when an insect has got into the ear, it is quite sufficient to spit into that organ, to make it come out. Among the counter-charms too, are reckoned, the practice of spitting into the urine the moment it is voided, of spitting into the shoe of the right foot before putting it on, and of spitting while a person is passing a place in which he has incurred any kind of peril.

Marcion of Smyrna, who has written a work on the virtues of simples, informs us that the sea scolopendra will burst asunder if spit upon; and that the same is the case with bram-ble-frogs, and other kinds of frogs. Opilius says that serpents will do the same, if a person spits into their open mouth; and Salpe tells us, that when any part of the body is asleep, the numbness may be got rid of by the person spitting into his lap, or touching the upper eyelid

with his spittle. If we are ready to give faith to such statements as these, we must believe also in the efficacy of the following practices: upon the entrance of a stranger, or when a person looks at an infant while asleep, it is usual for the nurse to spit three times upon the ground; and this, although infants are under the especial guardianship of the god Fascinus, the protector, not of infants only, but of generals as well, and a divinity whose worship is entrusted to the Vestal virgins, and forms part of the Roman rites. It is the image of this divinity that is attached beneath the triumphant car of the victorious general, protecting him, like some attendant physician, against the effects of envy; while, at the same time, equally salutary is the advice of the tongue, which warns him to be wise in time, that so Fortune may be prevailed upon by his prayers, not to follow, as the destroyer of his glory, close upon his back.

CHAP. 8.

REMEDIES DERIVED FROM THE WAX OF THE HUMAN EAR.

The human bite is also looked upon as one of the most dangerous of all. The proper remedy for it is human ear-wax: a thing that we must not be surprised at, seeing that, if applied immediately, it is a cure for the stings of scorpions even, and serpents. The best, however, for this purpose, is that taken from the ears of the wounded person. Agnails, too, it is said, may be cured in a similar manner. A human tooth, reduced to powder, is a cure, they say, for the sting of a serpent.

[Detailed table of contents](#)

CHAP. 9.

REMEDIES DERIVED FROM THE HUMAN HAIR, TEETH, ETC.

The first hair, it is said, that is cut from an infant's head, and, in fact, the hair of all persons that have not reached the age of puberty, attached to the limbs, will modify the attacks of gout. A man's hair, applied with vinegar, is a cure for the bite of a dog, and, used with oil or wine, for wounds on the head. It is said, too, if we choose to believe it, that the hair of a man torn down from the cross, is good for quartan fevers. Ashes, too, of burnt human hair are curative of carcinomata. If a woman takes the first tooth that; a child has shed, provided it has not touched the ground, and has it set in a bracelet, and wears it constantly upon her arm, it will preserve her from all pains in the uterus and adjacent parts. If the great toe is tied fast to the one next to it, it will reduce tumours in the groin; and if the two middle fingers of the right hand are slightly bound together with a linen thread, it will act as a preservative against catarrhs and ophthalmia. A stone, it is said, that has been voided by a patient suffering from calculi, if attached to the body above the pubes, will alleviate the pains of others similarly afflicted, as well as pains in the liver; it will have the effect, also, of facilitating delivery. Granius adds, however, that for this last purpose, the stone will be more efficacious if it has been extracted with the knife. Delivery, when near at hand, will be accelerated, if the man by whom the woman has conceived, unties his girdle, and, after tying it round her, unties it, adding at the same time this formula, "I have tied it, and I will untie it," and then taking his departure.

Detailed table of contents

CHAP. 10.

REMEDIES DERIVED FROM THE HUMAN BLOOD, THE SEXUAL CONGRESS, ETC.

The blood of the human body, come from what part it may, is most efficacious, according to Orpheus and Archelaiis, as an application for quinzey: they say, too, that if it is applied to the mouth of a person who has fallen down in a fit of epilepsy, he will come to himself immediately. Some say that, for epilepsy, the great toes should be pricked, and the drops of blood that exude therefrom applied to the face; or else, that a virgin should touch the patient with her right thumb — a circumstance that has led to the belief that persons suffering from epilepsy should eat the flesh of animals in a virgin state. Æschines of Athens used to cure quinzey, carcinoma, and affections of the tonsillary glands and uvula, with the ashes of burnt excrements, a medicament to which he gave the name of “botryon.” There are many kinds of diseases which disappear entirely after the first sexual congress, or, in the case of females, at the first appearance of menstruation; indeed, if such is not the case, they are apt to become chronic, epilepsy in particular. Even more than this—a man, it is said, who has been stung by a serpent or scorpion, experiences relief from the sexual congress; but the woman, on the other hand, is sensible of detriment. We are assured, too, that if persons, when washing their feet, touch the eyes three times with the water, they will never be subject to ophthalmia or other diseases of the eyes.

Detailed table of contents

CHAP. 11.

REMEDIES DERIVED FROM THE DEAD.

Scrofula, imposthumes of the parotid glands, and throat diseases, they say, may be cured by the contact of the hand of a person who has been carried off by an early death: indeed there are some who assert that any dead body will produce the same effect, provided it is of the same sex as the patient, and that the part affected is touched with the back of the left hand. To bite off a piece from wood that has been struck by lightning, the hands being held behind the back, and then to apply it to the tooth, is a sure remedy, they say, for toothache. Some persons recommend the tooth to be fumigated with the smoke of a burnt tooth, which has belonged to another person of the same sex; or else to attach to the person a dogtooth, as it is called, which has been extracted from a body before burial. Earth, they say, taken from out of a human skull, acts as a depilatory to the eyelashes; it is asserted, also, that any plant which may happen to have grown there, if chewed, will cause the teeth to come out; and that if a circle is traced round an ulcer with a human bone, it will be effectually prevented from spreading.

Some persons, again, mix water in equal proportions from three different wells, and, after making a libation with part of it in a new earthen vessel, administer the rest to patients suffering from tertian fever, when the paroxysms come on. So, too, in cases of quartan fever, they take a fragment of a nail from a cross, or else a piece of a halter that has been used for crucifixion, and, after wrapping it in wool, attach it to the patient's neck; taking care, the moment he has recovered, to conceal it in some hole to which the light of the sun cannot penetrate.

Detailed table of contents

CHAP. 12.

VARIOUS REVERIES AND DEVICES OF THE MAGICIANS.

The following are some of the reveries of magic. A whetstone upon which iron tools have been frequently sharpened, if put, without his being aware of it, beneath the pillow of a person sinking under the effects of poison, will make him give evidence and declare what poison has been administered, and at what time and place, though at the same time he will not disclose the author of the crime. When a person has been struck by lightning, if the body is turned upon the side which has sustained the injury, he will instantly recover the power of speech — that is quite certain. For the cure of inguinal tumours, some persons take the thrum of an old web, and after tying seven or nine knots in it, mentioning at each knot the name of some widow woman or other, attach it to the part affected. To assuage the pain of a wound, they recommend the party to take a nail or any other substance that has been trodden under foot, and to wear it, attached to the body with the thrum of a web. To get rid of warts, some lie in a footpath with the face upwards, when the moon is twenty days old at least, and after fixing their gaze upon it, extend their arms above the head, and rub themselves with anything within their reach. If a person is extracting a corn at the moment that a star shoots, he will experience an immediate cure, they say. By pouring vinegar upon the hinges of a door, a thick liniment is formed, which, applied to the forehead, will alleviate headache: an effect equally produced, we are told, by binding the temples with a halter with which a man has been hanged. When a fish-bone happens to stick in the throat, it will go down immediately, if the person plunges his feet into cold water; but where the accident has happened with any other kind of bone, the proper remedy is to apply to the head some fragments of bones taken from the same dish. In cases where bread has stuck in the throat, the best plan is to take some of the same bread, and insert it in both ears.

Detailed table of contents

CHAP. 13.

REMEDIES DERIVED FROM THE HUMAN EXCRETIONS.

In Greece, where everything is turned to account, the owners of the gymnasia have introduced the very excretions even of the human body among the most efficient remedies; so much so, indeed, that the scrapings from the bodies of the athletes are looked upon as possessed of certain properties of an emollient, calorific, resolvent, and expletive nature, resulting from the compound of human sweat and oil. These scrapings are used, in the form of a pessary, for inflammations and contractions of the uterus: similarly employed, they act as an emmenagogue, and are useful for reducing condylomata and inflammations of the rectum, as also for assuaging pains in the sinews, sprains, and nodosities of the joints. The scrapings obtained from the baths are still more efficacious for these purposes, and hence it is that they form an ingredient in maturative preparations. Such scrapings as are impregnated with wrestlers' oil, used in combination with mud, have a mollifying effect upon the joints, and are more particularly efficacious as a calorific and resolvent; but in other respects their properties are not so strongly developed.

The shameless and disgusting researches that have been made will quite transcend all belief, when we find authors of the very highest repute proclaiming aloud that the male seminal fluid is a sovereign remedy for the sting of the scorpion! In the case too, of women afflicted with sterility, they recommend the application of a pessary, made of the first excrement that is voided by an infant at the moment of its birth; the name they give it is "meconium." They have even gone so far, too, as to scrape the very filth from off the walls of the gymnasia, and to assert that this is also possessed of certain calorific properties. These scrapings are used as a resolvent for inflamed tumours, and are applied topically to ulcers upon aged people and children, and to excoriations and burns.

Detailed table of contents

CHAP. 14.

REMEDIES DEPENDING UPON THE HUMAN WILL.

It would be the less becoming then for me to omit all mention of the remedies which depend upon the human will. Total abstinence from food or drink, or from wine only, from flesh, or from the use of the bath, in cases where the health requires any of these expedients, is looked upon as one of the most effectual modes of treating diseases. To this class of remedies must be added bodily exercise, exertion of the voice, anointings, and frictions according to a prescribed method: for powerful friction, it should be remembered, has a binding effect upon the body, while gentle friction, on the other hand, acts as a laxative; so too, repeated friction reduces the body, while used in moderation it has a tendency to make flesh. But the most beneficial practice of all is to take walking or carriage exercise; this last being performed in various ways. Exercise on horseback is extremely good for affections of the stomach and hips, a voyage for phthisis, and a change of locality for diseases of long standing. So, too, a cure may sometimes be effected by sleep, by a recumbent position in bed, or by the use of emetics in moderation. To lie upon the back is beneficial to the sight, to lie with the face downwards is good for a cough, and to lie on the side is recommended for patients suffering from catarrh.

According to Aristotle and Fabianus, it is towards spring and autumn that we are most apt to dream; and they tell us that persons are most liable to do so when lying on the back, but never when lying with the face downwards. Theophrastus assures us that the digestion is accelerated by lying on the right side; while, on the other hand, it is retarded by lying with the face upwards. The most powerful, however, of all remedies, and one which is always at a person's own command, is the sun: violent friction, too, is useful by the agency of linen towels and body-scrappers. To pour warm water on the head before taking the vapour-bath, and cold water after it, is looked upon as a most beneficial practice; so, too, is the habit of taking cold water before food, of drinking it every now and then while eating, of taking it just before going to sleep, and, if practicable, of waking every now and then, and taking a draught. It is worthy also of remark, that there is no living creature but man that is fond of hot drinks, a proof that they are contrary to nature. It has been ascertained by experiment, that it is a good plan to rinse the mouth with undiluted wine, before going to sleep, for the purpose of sweetening the breath; to rinse the mouth with cold water an odd number of times every morning, as a preservative against tooth-ache; and to wash the eyes with oxycrate, as a preventive of ophthalmia. It has been remarked also, that the general health is improved by a varying regimen, subject to no fixed rules.

(5.) Hippocrates informs us that the viscera of persons who do not take the morning meal become prematurely aged and feeble; but then he has

pronounced this aphorism, it must be remembered, by way of suggesting a healthful regimen, and not to promote gluttony; for moderation in diet is, after all, the thing most conducive to health. L. Lucullus gave charge to one of his slaves to overlook him in this respect; and, a thing that reflected the highest discredit on him, when, now an aged man and laden with triumphs, he was feasting in the Capitol even, his hand had to be removed. from the dish to which he was about to help himself. Surely it was a disgrace for a man to be governed by his own slave more easily than by himself!

Detailed table of contents

CHAP. 15. (6.)

REMEDIES DERIVED FROM SNEEZING.

Sneezing, provoked by a feather, relieves heaviness in the head; it is said too, that to touch the nostrils of a mule with the lips, will arrest sneezing and hiccup. For this last purpose, Varro recommends us to scratch the palm, first of one hand and then of the other; while many say that it is a good plan to shift the ring from off the left hand to the longest finger of the right, and then to plunge the hands into hot water. Theophrastus says, that aged persons sneeze with greater difficulty than others.

[Detailed table of contents](#)

CHAP. 16.

REMEDIES DERIVED FROM THE SEXUAL CONGRESS.

Democritus spoke in condemnation of the sexual congress, as being merely an act through which one human being springs from another; and really, by Hercules! the more rarely it is used the better. Still however, athletes, we find, when they become dull and heavy, are re-established by it: the voice, too, is restored by it, when from being perfectly clear, it has degenerated into hoarseness. The congress of the sexes is a cure also for pains in the loins, dimness of the eyesight, alienation of the mental difficulties, and melancholy.

[Detailed table of contents](#)

CHAP. 17.

VARIOUS OTHER REMEDIES.

To sit by a pregnant woman, or by a person to whom any remedy is being administered, with the fingers of one hand inserted between those of the other, acts as a magic spell; a discovery that was made, it is said, when Alcmena was delivered of Hercules. If the fingers are thus joined, clasping one or both knees, or if the ham of one leg is first put upon the knee of the other, and then changed about, the omen is of still worse signification. Hence it is, that in councils held by generals and persons in authority, our ancestors forbade these postures, as being an impediment to all business. They have given a similar prohibition also with reference to sacrifices and the offering of public vows; but as to the usage of uncovering the head in presence of the magistrates, that has been enjoined, Varro says, not as a mark of respect, but with a view to health, the head being strengthened by the practice of keeping it uncovered.

When anything has got into the eye, it is a good plan to close the other; and when water has got into the right ear, the person should hop about on the left foot, with the head reclining upon the right shoulder, the reverse being done when the same has happened to the left ear. If the secretion of the phlegm produces coughing, the best way of stopping it is for another person to blow in the party's face. When the uvula is relaxed, another person should take the patient with his teeth by the crown, and lift him from the ground; while for pains in the neck, the hams should be rubbed, and for pains in the hams the neck. If a person is seized in bed with cramp in the sinews of the legs or thighs, he should set his feet upon the ground: so, too, if he has cramp on the left side, he should take hold of the great toe of the left foot with the right hand, and if on the right side, the great toe of the right foot with the left hand. For cold shiverings or for excessive bleeding at the nostrils, the extremities of the body should be well rubbed with sheep's wool. To arrest incontinence of urine, the extremities of the generative organs should be tied with a thread of linen or papyrus, and a binding passed round the middle of the thigh. For derangement of the stomach, it is a good plan to press the feet together, or to plunge the hands into hot water.

In addition to all this, in many cases it is found highly beneficial to speak but little; thus, for instance, Mæcenas Melissus, we are told, enjoined silence on himself for three years, in consequence of spitting blood after a convulsive fit. When a person is thrown from a carriage, or when, while mounting an elevation or lying extended at full length, he is menaced with any accident, or if he receives a blow, it is singularly beneficial to hold the breath; a discovery for which we are indebted to an animal, as already stated.

To thrust an iron nail into the spot where a person's head lay at the moment he was seized with a fit of epilepsy, is said to have the effect of curing him of

that disease. For pains in the kidneys, loins, or bladder, it is considered highly soothing to void the urine lying on the face at full length in a reclining bath. It is quite surprising how much more speedily wounds will heal if they are bound up and tied with a Hercules' knot: indeed, it is said, that if the girdle which we wear every day is tied with a knot of this description, it will be productive of certain beneficial effects, Hercules having been the first to discover the fact.

Demetrius, in the treatise which he has compiled upon the number Four, alleges certain reasons why drink should never be taken in proportions of four cyathi or sextarii. As a preventive of ophthalmia, it is a good plan to rub the parts behind the ears, and, as a cure for watery eyes, to rub the forehead. As to the presages which are derived from man himself, there is one to the effect that so long as a person is able to see himself reflected in the pupil of the patient's eye, there need be no apprehension of a fatal termination to the malady.

Detailed table of contents

CHAP. 18.

REMEDIES DERIVED FROM THE URINE.

The urine, too, has been the subject not only of numerous theories with authors, but of various religious observances as well, its properties being classified under several distinctive heads: thus, for instance, the urine of eunuchs, they say, is highly beneficial as a promoter of fruitfulness in females. But to turn to those remedies which we may be allowed to name without impropriety — the urine of children who have not arrived at puberty is a sovereign remedy for the poisonous secretions of the asp known as the “ptyas,” from the fact that it spits its venom into the eyes of human beings. It is good, too, for the cure of albugo, films and marks upon the eyes, white specks upon the pupils, and maladies of the eyelids. In combination with meal of fitches, it is used for the cure of burns, and, with a head of bulbed leek, it is boiled down to one half, in a new earthen vessel, for the treatment of suppurations of the ears, or the extermination of worms breeding in those organs: the vapour, too, of this decoction acts as an emmenagogue. Salpe recommends that the eyes should be fomented with it, as a means of strengthening the sight; and that it should be used as a liniment for sun scorches, in combination with white of egg, that of the ostrich being the most effectual, the application being kept on for a couple of hours.

Urine is also used for taking out ink spots. Male urine cures gout, witness the fullers for instance, who, for this reason, it is said, are never troubled with that disease. With stale urine some mix ashes of calcined oyster-shells, for the cure of eruptions on the bodies of infants, and all kinds of running ulcers: it is used, too, as a liniment for corrosive sores, burns, diseases of the rectum, chaps upon the body, and stings inflicted by scorpions. The most celebrated midwives have pronounced that there is no lotion which removes itching sensations more effectually; and, with the addition of nitre, they prescribe it for the cure of ulcers of the head, porrigo, and cancerous sores, those of the generative organs in particular. But the fact is, and there is no impropriety in saying so, that every person’s own urine is the best for his own case, due care being taken to apply it immediately, and unmixed with anything else; in such cases as the bite of a dog, for instance, or the quill of a hedge-hog entering the flesh, a sponge or some wool being the vehicle in which it is applied. Kneaded up with ashes, it is good for the bite of a mad dog, and for the cure of stings inflicted by serpents. As to the bite of the scolopendra, the effects of urine are said to be quite marvellous — the person who has been injured has only to touch the crown of his head with a drop of his own urine, and he will experience an instantaneous cure.

CHAP. 19.

INDICATIONS OF HEALTH DERIVED FROM THE URINE.

Certain indications of the health are furnished by the urine. Thus, for example, if it is white at first in the morning and afterwards high-coloured, the first signifies that the digestion is going on, the last that it is completed. When the urine is red, it is a bad sign; but when it is swarthy, it is the worst sign of all. So, too, when it is thick or full of bubbles, it is a bad sign; and when a white sediment forms, it is a symptom of pains in the region of the viscera or in the joints. A green-coloured urine is indicative of disease of the viscera, a pale urine of biliousness, and a red urine of some distemper in the blood. The urine is in a bad state, too, when certain objects form in it, like bran or fine clouds in appearance. A thin, white, urine also is in a diseased state; but when it is thick and possessed of an offensive smell, it is significant of approaching death: so, too, when with children it is thin and watery.

The adepts in magic expressly forbid a person, when about to make water, to uncover the body in the face of the sun or moon, or to sprinkle with his urine the shadow of any object whatsoever. Hesiod gives a precept, recommending persons to make water against an object standing full before them, that no divinity may be offended by their nakedness being uncovered. Osthanes maintains that every one who drops some urine upon his foot in the morning will be proof against all noxious medicaments.

CHAP. 20. (7.)

FORTY-ONE REMEDIES DERIVED FROM THE FEMALE SEX.

The remedies said to be derived from the bodies of females closely approach the marvellous nature of prodigies; to say nothing of still-born infants cut up limb by limb for the most abominable practices, expiations made with the menstrual discharge, and other devices which have been mentioned, not only by midwives but by harlots even as well! The smell of a woman's hair, burnt, will drive away serpents, and hysterical suffocations, it is said, may be dispelled thereby. The ashes of a woman's hair, burnt in an earthen vessel, or used in combination with litharge, will cure eruptions and prurigo of the eyes: used in combination with honey they will remove warts and ulcers upon infants; with the addition of honey and frankincense, they will heal wounds upon the head, and fill up all concavities left by corrosive ulcers; used with hogs' lard, they will cure inflammatory tumours and gout; and applied topically to the part affected, they will arrest erysipelas and hæmorrhage, and remove itching pimples on the body which resemble the stings of ants.

CHAP. 21.

REMEDIES DERIVED FROM WOMAN'S MILK.

As to the uses to which woman's milk has been applied, it is generally agreed that it is the sweetest and the most delicate of all, and that it is the best of remedies for chronic fevers and cœliac affections, when the woman has just weaned her infant more particularly. In cases, too, of sickness at stomach, fevers, and gnawing sensations, it has been found by experience to be highly beneficial; as also, in combination with frankincense, for abscesses of the mamillæ. When the eyes are bloodshot from the effects of a blow, or affected with pain or defluxion, it is a very good plan to inject woman's milk into them, more particularly in combination with honey and juice of daffodil, or else powdered frankincense. In all cases, however, the milk of a woman who has been delivered of a male child is the most efficacious, and still more so if she has had male twins; provided always she abstains from wine and food of an acrid nature. Mixed with the white of an egg in a liquid state, and applied to the forehead in wool, it arrests defluxions of the eyes. If a frog has spirted its secretions into the eye, woman's milk is a most excellent remedy; and for the bite of that reptile it is used both internally and externally.

It is asserted that if a person is rubbed at the same moment with the milk of both mother and daughter, he will be proof for the rest of his life against all affections of the eyes. Mixed with a small quantity of oil, woman's milk is a cure for diseases of the ears; and if they are in pain from the effects of a blow, it is applied warm with goose-grease. If the ears emit an offensive smell, a thing that is mostly the case in diseases of long standing, wool is introduced into those organs, steeped in woman's milk and honey. While symptoms of jaundice are still visible in the eyes, woman's milk is injected, in combination with elaterium. Taken as a drink, it is productive of singularly good effects, where the poison of the sea-hare, the buprestis, or, as Aristotle tells us, the plant dorycnium has been administered; as a preventive also of the madness produced by taking henbane. Woman's milk also, mixed with hemlock, is recommended as a liniment for gout; while some there are who employ it for that purpose in combination with wool-grease or goose-grease; a form in which it is used as an application for pains in the uterus. Taken as a drink, it arrests diarrhœa, Rabirius says, and acts as an emmenagogue; but where the woman has been delivered of a female child, her milk is of use only for the cure of face diseases.

Woman's milk is also a cure for affections of the lungs; and, mixed with the urine of a youth who has not arrived at puberty, and Attic honey, in the proportion of one spoonful of each, it removes singing in the ears, I find. Dogs which have once tasted the milk of a woman who has been delivered of a male child, will never become mad, they say.

CHAP. 22.

REMEDIES DERIVED FROM THE SPITTLE OF FEMALES.

A woman's fasting spittle is generally considered highly efficacious for bloodshot eyes: it is good also for defluxions of those organs, the inflamed corners of the eyes being moistened with it every now and then; the result, too, is still more successful, if the woman has abstained from food and wine the day before.

I find it stated that head-ache may be alleviated by tying a woman's fillet round the head.

CHAP. 23.

FACTS CONNECTED WITH THE MENSTRUAL DISCHARGE.

Over and above these particulars, there is no limit to the marvellous powers attributed to females. For, in the first place, hailstorms, they say, whirlwinds, and lightning even, will be scared away by a woman uncovering her body while her monthly courses are upon her. The same, too, with all other kinds of tempestuous weather; and out at sea, a storm may be lulled by a woman uncovering her body merely, even though not menstruating at the time. As to the menstrual discharge itself, a thing that in other respects, as already stated on a more appropriate occasion, is productive of the most monstrous effects, there are some ravings about it of a most dreadful and unutterable nature. Of these particulars, however, I do not feel so much shocked at mentioning the following. If the menstrual discharge coincides with an eclipse of the moon or sun, the evils resulting from it are irremediable; and no less so, when it happens while the moon is in conjunction with the sun; the congress with a woman at such a period being noxious, and attended with fatal effects to the man. At this period also, the lustre of purple is tarnished by the touch of a woman: so much more baneful is her influence at this time than at any other. At any other time, also, if a woman strips herself naked while she is menstruating, and walks round a field of wheat, the caterpillars, worms, beetles, and other vermin, will fall from off the ears of corn. Metrodorus of Scepsos tells us that this discovery was first made in Cappadocia; and that, in consequence of such multitudes of cantharides being found to breed there, it is the practice for women to walk through the middle of the fields with their garments tucked up above the thighs. In other places, again, it is the usage for women to go barefoot, with the hair dishevelled and the girdle loose: due precaution must be taken, however, that this is not done at sun-rise, for if so, the crop will wither and dry up. Young vines, too, it is said, are injured irremediably by the touch of a woman in this state; and both rue and ivy, plants possessed of highly medicinal virtues, will die instantly upon being touched by her.

Much as I have already stated on the virulent effects of this discharge, I have to state, in addition, that bees, it is a well-known fact, will forsake their hives if touched by a menstruous woman; that linen boiling in the cauldron will turn black, that the edge of a razor will become blunted, and that copper vessels will contract a fetid smell and become covered with verdigrise, on coming in contact with her. A mare big with foal, if touched by a woman in this state, will be sure to miscarry; nay, even more than this, at the very sight of a woman, though seen at a distance even, should she happen to be menstruating for the first time after the loss of her virginity, or for the first time, while in a state of virginity. The bitumen that is found in Judæa, will

yield to nothing but the menstrual discharge; its tenacity being overcome, as already stated, by the agency of a thread from a garment which has been brought in contact with this fluid. Fire itself even, an element which triumphs over every other substance, is unable to conquer this; for if reduced to ashes and then sprinkled upon garments when about to be scoured, it will change their purple tint, and tarnish the brightness of the colours. Indeed so pernicious are its properties, that women themselves, the source from which it is derived, are far from being proof against its effects; a pregnant woman, for instance, if touched with it, or indeed if she so much as steps over it, will be liable to miscarry.

Laïs and Elephant have given statements quite at variance, on the subject of abortives; they mention the efficacy for that purpose of charcoal of cabbage root, myrtle root, or tamarisk root, quenched in the menstrual discharge; they say that she-asses will be barren for as many years as they have eaten barley-corns steeped in this fluid; and they have enumerated various other monstrous and irreconcilable properties, the one telling us, for instance, that fruitfulness may be ensured by the very same methods, which, according to the statement of the other, are productive of barrenness; to all which stories it is the best plan to refuse credit altogether. Bithus of Dyrrhachium informs us that a mirror, which has been tarnished by the gaze of a menstuous female, will recover its brightness if the same woman looks steadily upon the back of it; he states, also, that all evil influences of this nature will be entirely neutralized, if the woman carries the fish known as the sur mullet about her person.

On the other hand, again, many writers say that, baneful as it is, there are certain remedial properties in this fluid; that it is a good plan, for instance, to use it as a topical application for gout, and that women, while menstruating, can give relief by touching scrofulous sores and imposthumes of the parotid glands, inflamed tumours, erysipelas, boils, and defluxions of the eyes. According to Laïs and Salpe, the bite of a mad (log, as well as tertian or quartan fevers, may be cured by putting some menstuous blood in the wool of a black ram and enclosing it in a silver bracelet; and we learn from Diotimus of Thebes that the smallest portion will suffice of any kind of cloth that has been stained therewith, a thread even, if inserted and worn in a bracelet. The midwife Sotira informs us that the most efficient cure for tertian and quartan fevers is to rub the soles of the patient's feet therewith, the result being still more successful if the operation is performed by the woman herself, without the patient being aware of it; she says, too, that this is an excellent method for reviving persons when attacked with epilepsy.

Icetidas the physician pledges his word that quartan fever may be cured by sexual intercourse, provided the woman is just beginning to menstruate. It is universally agreed, too, that when a person has been bitten by a dog and manifests a dread of water and of all kinds of drink, it will be quite sufficient to put under his clip a strip of cloth that has been dipped in this fluid; the result being that the hydrophobia will immediately disappear. This arises, no

doubt, from that powerful sympathy which has been so much spoken of by the Greeks, and the existence of which is proved by the fact, already mentioned, that dogs become mad upon tasting this fluid. It is a well-known fact, too, that the menstruous discharge, reduced to ashes, and applied with furnace soot and wax, is a cure for ulcers upon all kinds of beasts of burden; and that stains made upon a garment with it can only be removed by the agency of the urine of the same female. Equally certain it is, too, that this fluid, reduced to ashes and mixed with oil of roses, is very useful, applied to the forehead, for allaying head-ache, in women more particularly; as also that the nature of the discharge is most virulent in females whose virginity has been destroyed solely by the lapse of time.

Another thing universally acknowledged and one which I am ready to believe with the greatest pleasure, is the fact, that if the door-posts are only touched with the menstruous fluid all spells of the magicians will be neutralized — a set of men the most lying in existence, as any one may ascertain. I will give an example of one of the most reasonable of their prescriptions — Take the parings of the toe-nails and finger-nails of a sick person, and mix them up with wax, the party saying that he is seeking a remedy for a tertian, quartan, or quotidian fever, as the case may be; then stick this wax, before sunrise, upon the door of another person — such is the prescription they give for these diseases! What deceitful persons they must be if there is no truth in it! And how highly criminal, if they really do thus transfer diseases from one person to another! Some of them, again, whose practices are of a less guilty nature, recommend that the parings of all the finger-nails should be thrown at the entrance of ant-holes, the first ant to be taken which attempts to draw one into the hole; this, they say, must be attached to the neck of the patient, and he will experience a speedy cure.

CHAP. 24. (8.)

REMEDIES DERIVED FROM FOREIGN ANIMALS: THE ELEPHANT, EIGHT REMEDIES.

Such then are the remedies from human beings which may with any degree of propriety be described, and many of those only with the leave and good-will of the reader. The rest are of a most execrable and infamous nature, such, in fact, as to make me hasten to close my description of the remedies derived from man: we will therefore proceed to speak of the more remarkable animals, and the effects produced by them. The blood of the elephant, the male in particular, arrests all those defluxions known by the name of “rheumatismi.” Ivory shavings, it is said, in combination with Attic honey, are good for the removal of spots upon the face: with the sawdust, too, of ivory, hangnails are removed. By the touch of an elephant’s trunk head-ache is alleviated, if the animal happens to sneeze at the time more particularly. The right side of the trunk, attached to the body with red earth of Lemnos, acts powerfully as an aphrodisiac. Elephant’s blood is good for consumption, and the liver for epilepsy.

CHAP. 25.

TEN REMEDIES DERIVED FROM THE LION.

Lion's fat, mixed with oil of roses, protects the skin of the face from all kinds of spots, and preserves the whiteness of the complexion; it is remedial also for such parts of the body as have been frozen by snow, and for swellings in the joints. The frivolous lies of the magicians assert that persons who are anointed with lion's fat, will more readily win favour with kings and peoples; more particularly when the fat has been used that lies between the eyebrows of the animal—a place, in fact, where there is no fat to be found! The like effects they promise also from the possession of a lion's tooth, one from the right side in particular, as also the shaggy hairs that are found upon the lower jaw. The gall, used as an ointment in combination with water, improves the eyesight, and, employed with the fat of the same animal, is a cure for epilepsy; but a slight taste only must be taken of it, and the patient must run immediately after swallowing it, in order to digest it. A lion's heart, used as food, is curative of quartan fevers, and the fat, taken with oil of roses, of quotidian fevers. Wild beasts will fly from persons anointed with lion's fat, and it is thought to be a preservative even against treacherous practices.

Detailed table of contents

CHAP. 26.

TEN REMEDIES DERIVED FROM THE CAMEL.

A camel's brains, dried and taken in vinegar, are a cure, they say, for epilepsy: the same, too, with the gall, taken with honey; which is a remedy also for quincy. A camel's tail dried, it is said, is productive of diarrhœa, and ashes of burnt camel's dung, mixed with oil, make the hair curl. These ashes, applied topically, are very useful for dysentery, as also taken in drink, the proper dose being a pinch in three fingers at a time; they are curative also of epilepsy. Camel's urine it is said, is very useful to fullers, and is good for the cure of running sores. Barbarous nations, we are told, are in the habit of keeping it till it is five years old, and then taking it as a purgative, in doses of one semisextarius. The hairs of the tail, it is said, plaited and attached to the left arm, are a cure for quartan fevers.

CHAP. 27.

SEVENTY-NINE REMEDIES DERIVED FROM THE HYÆNA.

But of all animals, it is the hyæna that has been held in the highest admiration by the magicians, who have gone so far as to attribute to it certain magical virtues even, and the power of alluring human beings and depriving them of their senses. Of its change of sex each year, and other monstrous peculiarities in its nature, we have spoken already; we will now proceed to describe the medicinal virtues that are ascribed to it.

The hyæna, it is said, is particularly terrible to panthers; so much so, indeed, that they will not attempt to make the slightest resistance to it, and will never attack a man who has any portion of a hyæna's skin about him. A thing truly marvellous to tell of, if the hides of these two animals are hung up facing one another, the hair will fall from off the panther's skin! When the hyæna flies before the hunter, it turns off on the right, and letting the man get before it, follows in his track: should it succeed in doing which, the man is sure to lose his senses and fall from his horse even. But if, on the other hand, it turns off to the left, it is a sign that the animal is losing strength, and that it will soon be taken. The easiest method, however, of taking it, they say, is for the hunter to tie his girdle with seven knots, and to make as many knots in the whip with which he guides his horse. In addition to all this, so full of quirks and subtleties are the vain conceits of the magicians, they recommend the hyæna to be captured while the moon is passing through the sign of Gemini, and every hair of it to be preserved, if possible. They say, too, that the skin of the head is highly efficacious, if attached to a person suffering from headache; that the gall, applied to the forehead, is curative of ophthalmia; and that if the gall is boiled down with three cyathi of Attic honey and one ounce of saffron, it will be a most effectual preservative against that disease, the same preparation being equally good for the dispersion of films on the eyes and cataract. If, again, this preparation is kept till it is old, it will be all the better for improving the sight, due care being taken to preserve it in a box of Cyprian copper: they assert also, that it is good for the cure of argema, eruptions and excrescences of the eyes, and marks upon those organs. For diseases of the crystalline humours of the eyes, it is recommended to anoint them with the gravy of hyæna's liver roasted fresh, incorporated with clarified honey.

We learn also, from the same sources, that the teeth of the hyæna are useful for the cure of tooth-ache, the diseased tooth being either touched with them, or the animal's teeth being arranged in their regular order, and attached to the patient; that the shoulders of this animal are good for the cure of pains in the arms and shoulders; that the teeth, extracted from the left side of the jaw, and wrapped in the skin of a sheep or hegoat, are an effectual cure for pains in the

stomach; that the lights of the animal, taken with the food, are good for coeliac affections; that the lights, reduced to ashes and applied with oil, are also soothing to the stomach; that the marrow of the backbone, used with old oil and gall, is strengthening to the sinews; that the liver, tasted thrice just before the paroxysms, is good for quartan fevers; that the ashes of the vertebræ, applied in hyæna's skin with the tongue and right foot of a sea-calf and a bull's gall, the whole boiled up together, are soothing for gout; that for the same disease hyæna's gall is advantageously employed in combination with stone of Assos; that for cold shiverings, spasms, sudden fits of starting, and palpitations of the heart, it is a good plan to eat some portion of a hyæna's heart cooked, care being taken to reduce the rest to ashes, and to apply it with the brains of the animal to the part affected; that this last composition, or the gall applied alone, acts as a depilatory, the hairs being first plucked out which are wanted not to grow again; that by this method superfluous hairs of the eyelids may be removed; that the flesh of the loins, eaten and applied with oil, is a cure for pains in the loins; and that sterility in females may be removed by giving them the eye of this animal to eat, in combination with liquorice and dill, conception within three days being warranted as the result.

Persons afflicted with night-mare and dread of spectres, will experience relief, they say, by attaching one of the large teeth of a hyæna to the body, with a linen thread. In fits of delirium too, it is recommended to fumigate the patient with the smoke of one of these teeth, and to attach one in front of his chest, with the fat of the kidneys, or else the liver or skin. They assert also that a pregnant woman will never miscarry, if she wears suspended from her neck, the white flesh from a hyæna's breast, with seven hairs and the genitals of a stag, the whole tied up in the skin of a gazelle. The genitals, they say, eaten with honey, act as a stimulant upon a person, according to the sex, and this even though it should be the case of a man who has manifested an aversion to all intercourse with females.

Nay, even more than all this, we are assured that if the genitals and a certain joint of the vertebræ are preserved in a house with the hide adhering to them, they will ensure peace and concord between all members of the family; hence it is that this part is known as the "joint of the spine," or "Atlantian knot." This joint, which is the first, is reckoned among the remedies for epilepsy.

The fumes of the burnt fat of this animal will put serpents to flight, they say; and the jawbone, pounded with anise and taken with the food, is a cure for shivering fits. A fumigation made therewith has the effect of an emmenagogue; and such are the frivolous and absurd conceits of the professors of the magic art, that they boldly assert that if a man attaches to his arm a tooth from the right side of the upper jaw, he will never miss any object he may happen to aim at with a dart. The palate, dried and warmed with Egyptian alum, is curative of bad odours and ulcers of the mouth, care being taken to renew the application three times. Dogs, they say, will never bark at

persons who have a hyæna's tongue in the shoe, beneath the sole of the foot. The left side of the brain, applied to the nostrils, is said to have a soothing effect upon all dangerous maladies either in men or beasts. They say, too, that the skin of the forehead is a preservative against all fascinations; that the flesh of the neck, whether eaten or dried and taken in drink, is good for pains in the loins; that the sinews of the back and shoulders, used as a fumigation, are good for pains in the sinews; that the bristles of the snout, applied to a woman's lips, have all the effect of a philtre; and that the liver, administered in drink, is curative of griping pains and urinary calculi.

The heart, it is said, taken with the food or drink, is remedial for all kinds of pains in the body; the milt for pains in the spleen; the caul, in combination with oil, for inflammatory ulcers; and the marrow for pains in the spine and weakness in the sinews. The strings of the kidneys, they say, if taken with wine and frankincense, will restore fruitfulness, in cases where it has been banished through the agency of noxious spells; the uterus, taken in drink with the rind of a sweet pomegranate, is highly beneficial for diseases of the uterus; and the fat of the loins, used as a fumigation, removes all impediments to delivery, and accelerates parturition. The marrow of the back, attached to the body as an amulet, is an effectual remedy for fantastic illusions, and the genitals of the male animal, used as a fumigation, are good for the cure of spasms. For ophthalmia, ruptures, and inflammations, the feet, which are kept for the purpose, are touched; the left feet for affections on the right side of the body, and the right feet for affections on the left. The left foot, if laid upon the body of a woman in travail, will be productive, they say, of fatal effects; but the right foot, similarly employed, will facilitate delivery. The vesicle which has contained the gall, taken in wine or with the food, is beneficial for the cardiac disease; and the bladder, taken in wine, is a good preservative against incontinence of urine. The urine, too, which is found in the bladder, taken with oil, sesame, and honey, is said to be useful for diseases of long standing.

The first rib and the eighth, used as a fumigation, are said to be useful for ruptures; the vertebræ for women in travail; and the blood, in combination with polenta, for griping pains in the bowels. If the door-posts are touched with this blood, the various arts of the magicians will be rendered of no effect; they will neither be able to summon the gods into their presence nor to converse with them, whatever the method to which they have recourse, whether lamps or basin, water or globe, or any other method.

The flesh of the hyæna, taken as food, is said to be efficacious for the bite of a mad dog, and the liver still more so. The flesh or bones of a human being which have been found in the belly of a slain hyæna, used as a fumigation, are said to be remedial for gout: but if among these remains the nails are found, it is looked upon as a presage of death to some one among those who have captured it. The excrements or bones which have been voided by the animal at the moment when killed, are looked upon as counter-charms to magic spells. The dung found in the intestines is dried and administered in drink for

dysentery; and it is applied to all parts of the body with goose-grease, in the form of a liniment, in the case of persons who have received injury from some noxious medicament. By rubbing themselves with the grease, and lying upon the skin, of a hyæna, persons who have been bitten by dogs are cured.

On the other hand, the ashes of the left pastern-bone, they say, boiled with weasel's blood, and applied to a person's body, will ensure universal hatred; a similar effect being equally produced by the eye when boiled. But the most extraordinary thing of all is, their assertion that the extremity of the rectum of this animal is a preservative against all oppression on the part of chiefs and potentates, and an assurance of success in all petitions, judgments, and lawsuits, and this, if a person only carries it about him. The anus, according to them, has so powerful an effect as a philtre, that if it is worn on the left arm, a woman will be sure to follow the wearer the moment he looks at her. The hairs, too, of this part, reduced to ashes, and applied with oil to the body of a man who is living a life of disgraceful effeminacy, will render him not only modest, they assure us, but of scrupulous morals even.

Detailed table of contents

CHAP. 28.

NINETEEN REMEDIES DERIVED FROM THE CROCODILE.

For fabulous stories connected with it the crocodile may challenge the next place; and, indeed for cunning, the one which lives both upon land and in the water is fully its equal: for I would here remark, that there are two varieties of this animal. The teeth of the right jaw of the amphibious crocodile, attached to the right arm as an amulet, acts as an aphrodisiac, that is, if we choose to believe it. The eye-teeth of the animal, filled with frankincense — for they are hollow — are a cure for periodical fevers, care being taken to let the patient remain five days without seeing the person who has attached them to his body. A similar virtue is attributed to the small stones which are found in the belly of this animal, as being a check to the cold shiverings in fevers, when about to come on; and with the same object the Ægyptians are in the habit of anointing their sick with the fat of the crocodile.

The other kind of crocodile resembles it, but is much inferior in size: it lives upon land only, and among the most odoriferous flowers; hence it is that its intestines are so greatly in request, being filled as they are with a mass of agreeable perfumes. This substance is called “crocodilea,” and it is looked upon as extremely beneficial for diseases of the eyes, and for the treatment of films and cataract, being applied with leek-juice in the form of an ointment. Applied with oil of cyprus, it removes blemishes growing upon the face; and, employed with water, it is a cure for all those diseases, the nature of which it is to spread upon the face, while at the same time it restores the natural tints of the skin. An application of it makes freckles disappear, as well as all kinds of spots and pimples; and it is taken for epilepsy, in doses of two oboli, in oxymel. Used in the form of a pessary it acts as an emmenagogue. The best kind of crocodilea, is that which is the whitest, friable, and the lightest in weight: when rubbed between the fingers it should ferment like leaven. The usual method is to wash it, as they do white lead. It is sometimes adulterated with amyllum or with Cimolian earth, but the most common method of sophistication is to catch the crocodiles and feed them upon nothing but rice. It is recommended as one of the most efficient remedies for cataract to anoint the eyes with crocodile’s gall, incorporated with honey. We are assured also that it is highly beneficial for affections of the uterus to make fumigations with the intestines and rest of the body, or else to envelope the patient with wool impregnated with the smoke.

The ashes of the skin of either crocodile, applied with vinegar to such parts of the body as are about to undergo an incision, or indeed the very smell of the skin when burning, will render the patient insensible to the knife. The blood of either crocodile, applied to the eyes, effaces marks upon those organs and improves the sight. The body, with the exception of the head and feet, is

eaten, boiled, for the cure of sciatica, and is found very useful for chronic coughs, in children more particularly: it is equally good, too, for the cure of lumbago. These animals have a certain fat also, which, applied to the hair, makes it fall off; persons anointed with this fat are effectually protected against crocodiles, and it is the practice to drop it into wounds inflicted by them. A crocodile's heart, attached to the body in the wool of a black sheep without a speck of any other colour, due care too being taken that the sheep was the first lamb yeaned by its dam, will effectually cure a quartan fever, it is said.

CHAP. 29.

FIFTEEN REMEDIES DERIVED FROM THE CHAMÆLEON.

To these animals we shall annex some others that are equally foreign, and very similar in their properties. To begin then with the chameleon, which Democritus has considered worthy to be made the subject of an especial work, and each part of which has been consecrated to some particular purpose — This book, in fact, has afforded me no small amusement, revealing as it does, and exposing the lies and frivolities of the Greeks. — In size, the chameleon resembles the crocodile last mentioned, and only differs from it in having the back-bone arched at a more acute angle, and a larger tail. There is no animal, it is thought, more timid than this, a fact to which it owes its repeated changes of colour. It has a peculiar ascendancy over the hawk tribe; for, according to report, it has the power of attracting those birds, when flying above it, and then leaving them a voluntary prey for other animals. Democritus asserts that if the head and neck of a chamæleon are burnt in a fire made with logs of oak, it will be productive of a storm attended with rain and thunder; a result equally produced by burning the liver upon the tiles of a house. As to the rest of the magical virtues which he ascribes to this animal, we shall forbear to mention them, although we look upon them as unfounded; except, indeed, in some few instances where their very ridiculousness sufficiently refutes his assertions.

The right eye, he says, taken from the living animal and applied with goats' milk, removes diseases of the crystalline humours of the eyes; and the tongue, attached to the body as an amulet, is an effectual preservative against the perils of child-birth. He asserts also that the animal itself will facilitate parturition, if in the house at the moment; but if, on the other hand, it is brought from elsewhere, the consequences, he says, will be most dangerous. The tongue, he tells us, if taken from the animal alive, will ensure a favourable result to suits at law; and the heart, attached to the body with black wool of the first shearing, is a good preservative against the attacks of quartan fever.

He states also that the right fore-paw, attached to the left arm in the skin of the hyena, is a most effectual preservative against robberies and alarms at night; that the pap on the right side is a preventive of fright and panics; that the left foot is sometimes burnt in a furnace with the plant which also has the name of "chamæleon," and is then made up, with some unguent, into lozenges; and that these lozenges, kept in a wooden vessel, have the effect, if we choose to believe him, of making their owner invisible to others; that the possession, also, of the right shoulder of this animal will ensure victory over all adversaries or enemies, provided always the party throws the sinews of the shoulder upon the ground and treads them under foot. As to the left shoulder

of the chamæleon, I should be quite ashamed to say to what monstrous purposes Democritus devotes it; how that dreams may be produced by the agency thereof, and transferred to any person we may think proper; how that these dreams may be dispelled by the employment of the right foot; and how that lethargy, which has been produced by the right foot of this animal, may be removed by the agency of the left side.

So, too, head-ache, he tells us, may be cured by sprinkling wine upon the head, in which either flank of a chameleon has been macerated. If the feet are rubbed with the ashes of the left thigh or foot, mixed with sow's milk, gout, he says, will be the result. It is pretty generally believed, however, that cataract and diseases of the crystalline humours of the eyes may be cured by anointing those organs with the gall for three consecutive days; that serpents may be put to flight by dropping some of it into the fire; that weasels may be attracted by water into which it has been thrown; and that, applied to the body, it acts as a depilatory. The liver, they say, applied with the lungs of a bramble-frog, is productive of a similar effect: in addition to which, we are told that the liver counteracts the effects of philtres; that persons are cured of melancholy by drinking from the warm skin of a chamæleon the juice of the plant known by that name; and that if the intestines of the animal and their contents — we should bear in mind that in reality the animal lives without food — are mixed with apes' urine, and the doors of an enemy are besmeared with the mixture, he will, through its agency, become the object of universal hatred.

We are told, too, that by the agency of the tail, the course of rivers and torrents may be stopped, and serpents struck with torpor; that the tail, prepared with cedar and myrrh, and tied to a double branch of the date-palm, will divide waters that are smitten therewith, and so disclose every- thing that lies at the bottom — and I only wish that Democritus himself had been touched up with this branch of palm, seeing that, as he tells us, it has the property of putting an end to immoderate garrulity. It is quite evident that this philosopher, a man who has shown himself so sagacious in other respects, and so useful to his fellow-men, has been led away, in this instance, by too earnest a desire to promote the welfare of mankind.

Detailed table of contents

CHAP. 30.

FOUR REMEDIES DERIVED FROM THE SCINCUS.

Similar in appearance to the preceding animals is the scincus, which by some writers has been called the land crocodile; it is, however, whiter in appearance, and the skin is not so thick. But the main difference between it and the crocodile is in the arrangement of the scales, which run from the tail towards the head. The largest of these animals is the Indian scincus, and next to it that of Arabia; they are brought here salted. The muzzle and fat of the scincus, taken in white wine, act as an aphrodisiac; when used with satyrion and rocket-seed more particularly, in the proportion of one drachma of each, mixed with two drachmæ of pepper; the whole being made up into lozenges of one drachma each, and so taken in drink. The flesh from the flanks, taken internally in a similar manner, in doses of two oboli, with myrrh and pepper, is generally thought to be productive of a similar effect, and to be even more efficacious for the purpose. According to Apelles, the flesh of the scincus is good for wounds inflicted by poisoned arrows, whether taken before or after the wound is inflicted: it is used as an ingredient, also, in the most celebrated anti-dotes. Sextius tells us, that, taken in doses of more than one drachma, in one semisextarius of wine, the flesh is productive of deadly results: he adds, too, that a broth prepared from it, taken with honey, acts as an antaphrodisiac.

Detailed table of contents

CHAP. 31.

SEEN REMEDIES DERIVED FROM THE HIPPOPOTAMUS.

Between the crocodile, too, and the hippopotamus there is a certain affinity, frequenting as they do the same river, and being both of them of an amphibious nature. The hippopotamus was the first inventor of the practice of letting blood, a fact to which we have made allusion on a previous occasion: it is found, too, in the greatest numbers in the parts above the prefecture of Saïs.

The hide, reduced to ashes and applied with water, is curative of inflamed tumours, and the fat, as well as the dung, used as a fumigation, is employed for the cure of cold agues. With the teeth of the left side of the jaw, the gums are scarified for the cure of tooth-ache. The skin of the left side of the forehead, attached to the groin, acts as an antaphrodisiac; and an application of the ashes of the same part will cause the hair to grow when lost through alopecia. The testes are taken in water, in doses of one drachma, for the cure of injuries inflicted by serpents. The blood is made use of by painters.

Detailed table of contents

CHAP. 32.

FIVE REMEDIES DERIVED FROM THE LYNX.

To foreign countries, also, belongs the lynx, which of all quadrupeds is possessed of the most piercing sight. It is said that in the Isle of Carpathus a most powerful medicament is obtained by reducing to ashes the nails of the lynx, together with the hide; that these ashes, taken in drink, have the effect of checking abominable desires in men; and that, if they are sprinkled upon women, all libidinous thoughts will be restrained. They are good too for the removal of itching sensations in any part of the body. The urine of the lynx is a remedy for strangury; for which reason the animal, it is said, is in the habit of rooting up the ground and covering it the moment it is voided. It is mentioned, too, that this urine is an effectual remedy for pains in the throat. Thus much with reference to foreign animals.

Detailed table of contents

CHAP. 33. (9.)

REMEDIES FURNISHED IN COMMON BY ANIMALS OF THE SAME CLASS,
WHETHER WILD OR TAME. FIFTY-FOUR MEDICINAL USES OF MILK, WITH
OBSERVATIONS THEREON.

We will now return to our own part of the world, speaking, first of all, of certain remedies common to animals in general, but excellent in their nature; such as the use of milk, for example. The most beneficial milk to every creature is the mother's milk. It is highly dangerous for nursing women to conceive: children that are suckled by them are known among us as "colostrati," their milk being thick, like cheese in appearance — the name "colostra," it should be remembered, is given to the first milk secreted after delivery, which assumes a spongy, coagulated form. The most nutritive milk, in all cases, is woman's milk, and next to that goats' milk, to which is owing, probably, the fabulous story that Jupiter was suckled by a goat. The sweetest, next to woman's milk, is camels' milk; but the most efficacious, medicinally speaking, is asses' milk. It is in animals of the largest size and individuals of the greatest bulk, that the milk is secreted with the greatest facility. Goats' milk agrees the best with the stomach, that animal browsing more than grazing. Cows' milk is considered more medicinal, while ewes' milk is sweeter and more nutritive, but not so well adapted to the stomach, it being more oleaginous than any other.

Every kind of milk is more aqueous in spring than in summer, and the same in all cases where the animal has grazed upon a new pasture. The best milk of all is that which adheres to the finger nail, when placed there, and does not run from off it. Milk is most harmless when boiled, more particularly if sea pebbles have been boiled with it. Cows' milk is the most relaxing, and all kinds of milk are less apt to inflate when boiled. Milk is used for all kinds of internal ulcerations, those of the kidneys, bladder, intestines, throat, and lungs in particular; and externally, it is employed for itching sensations upon the skin, and for purulent eruptions, it being taken fasting for the purpose. We have already stated, when speaking of the plants, how that in Arcadia cows' milk is administered for phthisis, consumption, and cachexy. Instances are cited, also, of persons who have been cured of gout in the hands and feet, by drinking asses' milk.

To these various kinds of milk, medical men have added another, to which they have given the name of "schiston;" the following being the usual method of preparing it. Goats' milk, which is used in preference for the purpose, is boiled in a new earthen vessel, and stirred with branches of a fig-tree newly gathered, as many cyathi of honied wine being added to it as there are semisextarii of milk. When the mixture boils, care is taken to prevent it running over, by plunging into it a silver cyathus measure filled with cold water, none of the water being allowed to escape. When taken off the fire, the

constituent parts of it divide as it cools, and the whey is thus separated from the milk. Some persons, again, take this whey, which is now very strongly impregnated with wine, and, after boiling it down to one third, leave it to cool in the open air. The best way of taking it, is in doses of one semisextarius, at stated intervals, during five consecutive days; after taking it, riding exercise should be used by the patient. This whey is administered in cases of epilepsy, melancholy, paralysis, leprosy, elephantiasis, and diseases of the joints.

Milk is employed as an injection where excoriations have been caused by the use of strong purgatives; in cases also where dysentery is productive of chafing, it is similarly employed, boiled with sea pebbles or a ptisan of barley. Where, however, the intestines are excoriated, cows' milk or ewes' milk is the best. New milk is used as an injection for dysentery; and in an unboiled state, it is employed for affections of the colon and uterus, and for injuries inflicted by serpents. It is also taken internally as an antidote to the venom of cantharides, the pine-caterpillar, the buprestis, and the salamander. Cows' milk is particularly recommended for persons who have taken colchicum, hemlock, dorycnium, or the flesh of the seahare; and asses' milk, in cases where gypsum, white-lead, sulphur, or quick-silver, have been taken internally. This last is good too for constipation attendant upon fever, and is remarkably useful as a gargle for ulcerations of the throat. It is taken, also, internally, by patients suffering from atrophy, for the purpose of recruiting their exhausted strength; as also in cases of fever unattended with head-ache. The ancients held it as one of their grand secrets, to administer to children, before taking food, a semisextarius of asses' milk, or for want of that, goats' milk; a similar dose, too, was given to children troubled with chafing of the rectum at stool. It is considered a sovereign remedy for hardness of breathing, to take cows' milk whey, mixed with nasturtium. In cases of ophthalmia, too, the eyes are fomented with a mixture of one semisextarius of milk and four drachmæ of pounded sesame.

Goats' milk is a cure for diseases of the spleen; but in such case the goats must fast a couple of days, and be fed on ivyleaves the third; the patient, too, must drink the milk for three consecutive days, without taking any other nutriment. Milk, under other circumstances, is detrimental to persons suffering from head-ache, liver complaints, diseases of the spleen, and affections of the sinews; it is bad for fevers, also, vertigo — except, indeed, where it is required as a purgative — oppression of the head, coughs, and ophthalmia. Sows' milk is extremely useful in cases of tenesmus, dysentery, and phthisis; authors have been found too, to assert that it is very wholesome for females.

CHAP. 34.

TWELVE REMEDIES DERIVED FROM CHEESE.

We have already spoken of the different kinds of cheese when treating of the mamillæ and other parts of animals. Sextius attributes the same properties to mares' milk cheese that he does to cheese made of cows' milk: to the former he gives the names of "hippace." Cheese is best for the stomach when not salted, or, in other words, when new cheese is used. Old [salted] cheese has a binding effect upon the bowels, and reduces the flesh, but is more wholesome to the stomach [than new salted cheese]. Indeed, we may pronounce of aliments in general, that salt meats reduce the system, while fresh food has a tendency to make flesh. Fresh cheese, applied with honey, effaces the marks of bruises. It acts, also, emolliently upon the bowels; and, taken in the form of tablets, boiled in astringent wine and then toasted with honey on a platter, it modifies and alleviates griping pains in the bowels.

The cheese known as "saprum," is beaten up, in wine, with salt and dried sorb apples, and taken in drink, for the cure of celiac affections. Goats' milk cheese, pounded and applied to the part affected, is a cure for carbuncle of the generative organs; sour cheese, also, with oxymel, is productive of a similar effect. In the bath it is used as a friction, alternately with oil, for the removal of spots.

Detailed table of contents

CHAP. 35.

TWENTY-FIVE REMEDIES DERIVED FROM BUTTER.

From milk, too, butter is produced; held as the most delicate of food among barbarous nations, and one which distinguishes the wealthy from the multitude at large. It is mostly made from cows' milk, and hence its name; but the richest butter is that made from ewes' milk. There is a butter made also from goats' milk; but previously to making it, the milk should first be warmed, in winter. In summer it is extracted from the milk by merely shaking it to and fro in a tall vessel, with a small orifice at the mouth to admit the air, but otherwise closely stopped, a little water being added to make it curdle the sooner. The milk that curdles the most, floats upon the surface; this they remove, and, adding salt to it, give it the name of "oxygala." They then take the remaining part and boil it down in pots, and that portion of it which floats on the surface is butter, a substance of an oily nature. The more rank it is in smell, the more highly it is esteemed. When old, it forms an ingredient in numerous compositions. It is of an astringent, emollient, repletive, and purgative nature.

Detailed table of contents

CHAP. 36.

OXYGALA: ONE REMEDY.

Oxygala, too, is prepared another way, sour milk being added to the fresh milk which is wanted to curdle. This preparation is extremely wholesome to the stomach: of its properties we shall have occasion to speak in another place.

Detailed table of contents

CHAP. 37.

THE VARIOUS USES OF FAT AND OBSERVATIONS UPON IT, FIFTY-TWO IN NUMBER.

Among the remedies common to living creatures, fat is the substance held in the next highest esteem, that of swine in particular, which was employed by the ancients for certain religious purposes even: at all events, it is still the usage for the newly-wedded bride, when entering her husband's house, to touch the door-posts with it. There are two methods of keeping hogs' lard, either salted or fresh; indeed, the older it is, the better. The Greek writers have now given it the name of "axungia," or axle-grease, in their works. Nor, in fact, is it any secret, why swine's fat should be possessed of such marked properties, seeing that the animal feeds to such a great extent upon the roots of plants — owing too, to which, its dung is applied to such a vast number of purposes. It will be as well, therefore, to premise, that I shall here speak only of the hog that feeds in the open field, and no other; of which kind it is the female that is much the most useful-if she has never farrowed, more particularly. But it is the fat of the wild boar that is held in by far the highest esteem of all.

The distinguishing properties, then, of swine's-grease, are emollient, calorific, resolvent, and detergent. Some physicians recommend it as an ointment for the gout, mixed with goose grease, bull-suet, and wool-grease: in cases, however, where the pain is persistent, it should be used in combination with wax, myrtle, resin, and pitch. Hogs' lard is used fresh for the cure of burns, and of blains, too, caused by snow: with ashes of burnt barley and nutgalls, in equal proportions, it is employed for the cure of chilblains. It is good also for excoriations of the limbs, and for dispelling weariness and lassitude arising from long journeys. For the cure of chronic cough, new lard is boiled down, in the proportion of three ounces to three cyathi of wine, some honey being added to the mixture. Old lard too, if it has been kept without salt, made up into pills and taken internally, is a cure for phthisis: but it is a general rule not to use it salted in any cases except where detergents are required, or where there are no symptoms of ulceration. For the cure of phthisis, some persons boil down three ounces of hogs' lard and honied wine, in three cyathi of ordinary wine; and after swathing the sides, chest, and shoulders of the patient with compresses steeped in the preparation, administer to him, every four days, some tar with an egg: indeed, so potent is this composition, that if it is only attached to the knees even, the flavour of it will ascend to the mouth, and the patient will appear to spit it out, as it were.

The grease of a sow that has never farrowed, is the most useful of all cosmetics for the skin of females; but in all cases, hogs' lard is good for the cure of itch-scab, mixed with pitch and beef-suet in the proportion of one-third, the whole being made lukewarm for the purpose. Fresh hogs' lard,

applied as a pessary, imparts nutriment to the infant in the womb, and prevents abortion. Mixed with white lead or litharge, it restores scars to their natural colour; and, in combination with sulphur, it rectifies malformed nails. It prevents the hair also from falling off; and, applied with a quarter of a nutgall, it heals ulcers upon the head in females. When well smoked, it strengthens the eyelashes. Lard is recommended also for phthisis, boiled down with old wine, in the proportion of one ounce to a semisextarius, till only three ounces are left; some persons add a little honey to the composition. Mixed with lime, it is used as a liniment for inflamed tumours, boils, and indurations of the mamillæ: it is curative also of ruptures, convulsions, cramps, and sprains. Used with white hellebore, it is good for corns, chaps, and callosities; and, with pounded earthen-ware which has held salted provisions, for imposthumes of the parotid glands and scrofulous sores. Employed as a friction in the bath, it removes itching sensations and pimples: but for the treatment of gout there is another method of preparing it, by mixing it with old oil, and adding pounded sarcophagus stone and cinquefoil bruised in wine, or else with lime or ashes. A peculiar kind of plaster is also made of it for the cure of inflammatory ulcers, seventy-five denarii of hogs' lard being mixed with one hundred of litharge.

It is reckoned a very good plan also to anoint ulcers with boars' grease, and, if they are of a serpiginous nature, to add resin to the liniment. The ancients used to employ hogs' lard in particular for greasing the axles of their vehicles, that the wheels might revolve the more easily, and to this, in fact, it owes its name of "axungia." When hogs' lard has been used for this purpose, incorporated as it is with the rust of the iron upon the wheels, it is remarkably useful as an application for diseases of the rectum and of the generative organs. The ancient physicians, too, set a high value upon the medicinal properties of hogs' lard in an unmixed state: separating it from the kidneys, and carefully removing the veins, they used to wash and rub it well in rain water, after which they boiled it several times in a new earthen vessel, and then put it by for keeping. It is generally agreed that it is more emollient, calorific, and resolvent, when salted; and that it is still more useful when it has been rinsed in wine.

Massurius informs us, that the ancients set the highest' value of all upon the fat of the wolf: and that it was for this reason that the newly-wedded bride used to anoint the doorposts of her husband's house with it, in order that no noxious spells might find admittance.

[Detailed table of contents](#)

CHAP. 38.

SUET.

Corresponding with the grease of the swine, is the suet that is found in the ruminating animals, a substance employed in other ways, but no less efficacious in its properties. The proper mode of preparing it, in all cases, is to take out the veins and to rinse it in sea or salt-water, after which it is beaten up in a mortar, with a sprinkling of sea-water in it. This done, it is boiled in several waters, until, in fact, it has lost all smell, and is then bleached by continual exposure to the sun; that of the most esteemed quality being the fat which grows about the kidneys. In case stale suet is required for any medicinal purpose, it is recommended to melt it first, and then to wash it in cold water several times; after which, it must again be melted with a sprinkling of the most aromatic wine that can be procured, it being then boiled again and again, until the rank smell has totally disappeared.

Many persons recommend that the fat of bulls, lions, panthers, and camels, in particular, should be thus prepared. As to the various uses to which these substances are applied, we shall mention them on the appropriate occasions.

Detailed table of contents

CHAP. 39.

MARROW.

Common too, to all these animals, is marrow; a substance which in all cases is possessed of certain emollient, expletive, desiccative, and calorific properties. The most highly esteemed of all is deer's marrow, the next best being that of the calf, and then that of the goat, both male and female. These substances are prepared before autumn, by washing them in a fresh state, and drying them in the shade; after which they are passed through a sieve, and then strained through linen, and put by in earthen pots for keeping, in a cool spot.

[Detailed table of contents](#)

CHAP. 40.

GALL.

But among the substances which are furnished in common by the various animals, it is the gall, we may say, that is the most efficacious of all. The properties of this substance are of a calorific, pungent, resolvent, extractive, and dispersive nature. The gall of the smaller animals is looked upon as the most penetrating; for which reason it is that it is generally considered the most efficacious for the composition of eye-salves. Bull's gall is possessed of a remarkable degree of potency, having the effect of imparting a golden tint to the surface of copper even and to vessels made of other metals. Gall in every case is prepared in the following manner: it is taken fresh, and the orifice of the vesicle in which it is contained being tied fast with a strong linen thread, it is left to steep for half an hour in boiling water; after which it is dried in the shade, and then put away for keeping, in honey.

That of the horse is condemned, being reckoned among the poisons only. Hence it is that the Flamen of the Sacrifices is not allowed to touch a horse, notwithstanding that it is the custom to immolate one of these animals at the public sacrifices at Rome.

Detailed table of contents

CHAP. 41.

BLOOD.

The blood, also, of the horse is possessed of certain corrosive properties; and so, too, is mare's blood-except, indeed, where the animal has not been covered-it having the effect of cauterizing the margins of ulcers, and so enlarging them. Bull's blood too, taken fresh, is reckoned among the poisons; except, indeed, at Ægira, at which place the priestess of the Earth, when about to foretell coming events, takes a draught of bull's blood before she descends into the cavern: so powerful, in fact, is the agency of that sympathy so generally spoken of, that it may occasionally originate, we find, in feelings of religious awe, or in the peculiar nature of the locality.

Drusus, the tribune of the people, drank goats' blood, it is said; it being his object by his pallid looks to suggest that his enemy, Q. Cæpio, had given him poison, and so expose him to public hatred. So remarkably powerful is the blood of the hegoat, that there is nothing better in existence for sharpening iron implements, the rust produced by this blood giving them a better edge even than a file. Considering, however, that the blood of all animals cannot be reckoned as a remedy in common, will it not be advisable, in preference, to speak of the effects that are produced by that of each kind?

Detailed table of contents

CHAP. 42.

PECULIAR REMEDIES DERIVED FROM VARIOUS ANIMALS, AND CLASSIFIED ACCORDING TO THE MALADIES. REMEDIES AGAINST THE POISON OF SERPENTS, DERIVED FROM THE STAG, THE FAWN, THE OPHION, THE SHE-GOAT, THE KID, AND THE ASS.

We will therefore classify the various remedies, according to the maladies for which they are respectively used; and, first of all, those to which man has recourse for injuries inflicted by serpents. That deer are destructive to those reptiles no one is ignorant; as also of the fact that they drag them from their holes when they find them, and so devour them. And it is not only while alive and breathing that deer are thus fatal to serpents, but even when dead and separated limb from limb. The fumes of their horns, while burning, will drive away serpents, as already stated; but the bones, it is said, of the upper part of a stag's throat, if burnt upon a fire, will bring those reptiles together. Persons may sleep upon a deer's skin in perfect safety, and without any apprehension of attacks by serpents; its rennet too, taken with vinegar, is an effectual antidote to the stings of those reptiles; indeed, if it has been only touched by a person, he will be for that day effectually protected from them. The testes, dried, or the genitals of the male animal, are considered to be very wholesome, taken in wine, and so are the umbles, generally known as the "centipellio." Persons having about them a deer's tooth, or who have taken the precaution of rubbing the body with a deer or fawn's marrow, will be sure to repel the attacks of all serpents.

But the most effectual remedy of all is thought to be the rennet of a fawn that has been cut from the uterus of the dam, as already mentioned in another place. Deer's blood, burnt upon a fire of lentisk wood, with dracontium, cunilago, and alkanet, will attract serpents, they say; while, on the other hand, if the blood is removed and pyrethrum substituted for it, they will take to flight.

I find an animal mentioned by Greek writers, smaller than the stag, but resembling it in the hair, and to which they give the name of "ophion." Sardinia, they say, is the only country that produces it; I am of opinion, however, that it is now extinct, and for that reason I shall not enlarge upon its medicinal properties.

(10.) As a preservative against the attacks of serpents, the brains and blood of the wild boar are held in high esteem: the liver also, dried and taken in wine with rue; and the fat, used with honey and resin. Similar properties are attributed to the liver of the domesticated boar and the outer filaments, and those only, of the gall, these last being taken in doses of four denarii; the brains also, taken in wine, are equally effectual. The fumes of the burning horns or hair of a she-goat will repel serpents, they say: the ashes, too, of the horns, used either internally or externally, are thought to be an antidote to

their poison. A similar effect is attributed to goats' milk, taken with Taminian grapes; to the urine of those animals, taken with squill vinegar; to goats' milk cheese, applied with origanum; and to goat suet, used with wax.

In addition to all this, as will be seen hereafter, there are a thousand other remedial properties attributed to this animal; a fact which surprises me all the more, seeing that the goat, it is said, is never free from fever. The wild animals of the same species, which are very numerous, as already stated, have a still greater efficacy attributed to them; but the hegoat has certain properties peculiar to itself, and Democritus attributes properties still more powerful to the animal when it has been the only one yeaned. It is recommended also to apply she-goat's dung, boiled in vinegar, to injuries inflicted by serpents, as also the ashes of fresh dung mixed with wine. As a general rule, persons who find that they are recovering but slowly from injuries inflicted by a serpent, will find their health more speedily re-established by frequenting the stalls where goats are kept. Those, however, whose object is a more assured remedy, attach immediately to the wound the paunch of a she-goat killed for the purpose, dung and all. Others, again, use the flesh of a kid just killed, and fumigate it with the singed hair, the smell of which has the effect of repelling serpents.

For stings of serpents, as also for injuries inflicted by the scorpion and shrew-mouse, some employ the skin of a goat newly killed, as also the flesh and dung of a horse that has been out at pasture, or a hare's rennet in vinegar. They say, too, that if a person has the body well rubbed with a hare's rennet, he will never receive injury from venomous animals. When a person has been stung by a scorpion, she-goat's dung, boiled with vinegar, is considered a most efficient remedy: in cases too, where a buprestis has been swallowed, bacon and the broth in which it has been boiled, are highly efficacious. Nay, what is even more than this, if a person applies his mouth to an ass's ear, and says that he has been stung by a scorpion, the whole of the poison, they say, will immediately pass away from him and be transferred to the animal. All venomous creatures, it is said, are put to flight by a fumigation made by burning an ass's lights. It is considered an excellent plan too, to fumigate persons, when stung by a scorpion, with the smoke of burnt calves' dung.

Detailed table of contents

CHAP. 43.

REMEDIES FOR THE BITE OF THE MAD DOG. REMEDIES DERIVED FROM THE CALF, THE HE-GOAT, AND VARIOUS OTHER ANIMALS.

When a person has been bitten by a mad dog, it is the practice to make an incision round the wound to the quick, and then to apply raw veal to it, and to make the patient take either veal broth or hogs' lard, mixed with lime internally. Some persons recommend a he-goat's liver, and maintain that if it is applied to the wound the patient will never be attacked with hydrophobia. She-goat's dung, too, is highly spoken of, applied with wine, as also the dung of the badger, cuckoo, and swallow, boiled and taken in drink.

For bites inflicted by other animals, dried goats' milk cheese is applied with origanum and taken with the drink; and for injuries caused by the human teeth, boiled beef is applied; veal, however, is still more efficacious for the purpose, provided it is not removed before the end of four days.

CHAP. 44.

REMEDIES TO BE ADOPTED AGAINST ENCHANTMENTS.

The dried muzzle of a wolf, they say, is an effectual preservative against the malpractices of magic; and it is for this reason that it is so commonly to be seen fastened to the doors of farm-houses. A similar degree of efficacy, it is thought, belongs to the skin of the neck, when taken whole from the animal. Indeed, so powerful is the influence of this animal, in addition to what we have already stated, that if a horse only treads in its track, it will be struck with torpor in consequence.

Detailed table of contents

CHAP. 45.

REMEDIES FOR POISONS.

In case where persons have swallowed quicksilver, bacon is the proper remedy to be employed. Poisons are neutralized by taking asses' milk; henbane more particularly, mistletoe, hemlock, the flesh of the sea-hare, opocarpathon, pharicon, and dorycnium: the same, too, where coagulated milk has been productive of bad effects, for the biestings, or first curdled milk, should be reckoned as nothing short of a poison. We shall have to mention many other uses to which asses' milk is applied; but it should be remembered that in all cases it must be used fresh, or, if not, as new as possible, and warmed, for there is nothing that more speedily loses its virtue. The bones, too, of the ass are pounded and boiled, as an antidote to the poison of the sea-hare. The wild ass is possessed of similar properties in every respect, but in a much higher degree.

Of the wild horse the Greek writers have made no mention, it not being a native of their country; we have every reason to believe, however, that it has the same properties as the animal in a tame state, but much more fully developed. Mares' milk effectually neutralizes the venom of the sea-hare and all narcotic poisons. Nor had the Greeks any knowledge from experience of the urns and the bison, although in India the forests are filled with herds of wild oxen: it is only reasonable, however, to conclude that all their medicinal properties must be much more highly developed than in the animal as found among us. It is asserted also, that cows' milk is a general counter-poison, in the cases above-mentioned, more particularly, as also where the poison of ephemeron has settled internally, or cantharides have been administered; it acting upon the poison by vomit. Broth, too, made from goats' flesh, neutralizes the effects of cantharides, in a similar manner, it is said. To counteract the corrosive poisons which destroy by ulceration, veal or beef-suet is resorted to; and in cases where a leech has been swallowed, butter is the usual remedy, with vinegar heated with a red-hot iron. Indeed, butter employed by itself is a good remedy for poisons, for where oil is not to be procured, it is an excellent substitute for it. Used with honey, butter heals injuries inflicted by millepedes. The broth of boiled tripe, it is thought, is an effectual repellent of the above-mentioned poisons, aconite and hemlock more particularly; veal-suet also has a similar repute.

Fresh goats' milk cheese is given to persons who have taken mistletoe, and goats' milk itself is a remedy for cantharides. Taken with Taminian grapes, goats' milk is an antidote to the effects of ephemeron. Goats' blood, boiled down with the marrow, is used as a remedy for the narcotic poisons, and kids' blood for the other poisons. Kid's rennet is administered where persons have taken mistletoe, the juice of the white chamæleon, or bull's blood: for which

last, hare's rennet in vinegar is also used by way of antidote. For injuries inflicted by the pastinaca, and the stings or bites of all kinds of marine animals, hare's rennet, kid's rennet, or lamb's rennet is taken, in doses of one drachma, in wine. Hare's rennet, too, generally forms an ingredient in the antidotes for poisons.

The moth that is seen fluttering about the flame of a lamp is generally reckoned in the number of the noxious substances: its bad effects are neutralized by the agency of goat's liver. Goat's gall, too, is looked upon as an antidote to venomous preparations from the field weazel. But we will now return to the other remedies, classified according to the various diseases.

[Detailed table of contents](#)

CHAP. 46. (11.)

-REMEDIES FOR DISEASES OF THE HEAD, AND FOR ALOPECY.

Bears' grease, mixed with ladanum and the plant adiantum, prevents the hair from falling off; it is a cure also for alopecy and defects in the eyebrows, mixed with the fungus from the wick of a lamp, and the soot that is found in the nozzle. Used with wine, it is good for the cure of porrigo, a malady which is also treated with the ashes of deer's horns in wine: this last substance also prevents the growth of vermin in the hair. For porrigo some persons employ goat's gall, in combination with Cimolian chalk and vinegar, leaving the preparation to dry for a time on the head. Sow's gall, too, mixed with bull's urine, is employed for a similar purpose; and when old, it is an effectual cure, with the addition of sulphur, for furfuraceous eruptions. The ashes, it is thought, of an ass's genitals, will make the hair grow more thickly, and prevent it from turning grey; the proper method of applying it being to shave the head and to pound the ashes in a leaden mortar with oil. Similar effects are attributed to the genitals of an ass's foal, reduced to ashes and mixed with urine; some nard being added to render the mixture less offensive. In cases of alopecy the part affected is rubbed with bull's gall, warmed with Egyptian alum. Running ulcers of the head are successfully treated with bull's urine, or stale human urine, in combination with cyclaminos and sulphur: but the most effectual remedy is calf's gall, a substance which, heated with vinegar, has also the effect of exterminating lice. Veal suet, pounded with salt and applied to ulcers of the head, is a very useful remedy: the fat, too, of the fox is highly spoken of, but the greatest value is set upon cats' dung, applied in a similar manner with mustard.

Powdered goats' horns, or the horns reduced to ashes, those of the he-goat in particular, with the addition of nitre, tamarisk-seed, butter, and oil, are remarkably effectual for preventing the hair from coming off, the head being first shaved for the purpose. So too, the ashes of burnt goats' flesh, applied to the eye-brows with oil, impart to them a black tint. By using goats' milk, they say, lice may be exterminated; and the dung of those animals, with honey, is thought to be a cure for alopecy: the ashes, too, of the hoofs, mixed with pitch, prevent the hair from coming off.

The ashes of a burnt hare, mixed with oil of myrtle, alleviate head-ache, the patient drinking some water that has been left in the trough after an ox or ass has been drinking there. The male organs of a fox, worn as an amulet, are productive, if we choose to believe it, of a similar effect: the same, too, with the ashes of a burnt deer's horn, applied with vinegar, rose oil, or oil of iris.

CHAP. 47.

-REMEDIES FOR AFFECTIONS OF THE EYES.

For defluxions of the eyes, beef suet, boiled with oil, is applied to the parts affected; and for eruptions of those organs, ashes of burnt deer's horns are similarly employed, the tips of the horns being considered the most effectual for the purpose. For the cure of cataract, it is reckoned a good plan to apply a wolf's excrements: the same substance, too, reduced to ashes, is used for the dispersion of films, in combination with Attic honey. Bear's gall, too, is similarly employed; and for the cure of epinyctis, wild boar's lard, mixed with oil of roses, is thought to be very useful. An ass's hoof, reduced to ashes and applied with asses' milk, is used for the removal of marks in the eyes and indurations of the crystalline humours. Beef marrow, from the right fore leg, beaten up with soot, is employed for affections of the eyebrows, and for diseases of the eyelids and corners of the eyes. For the same purpose, also, a sort of calliblepharon is prepared from soot, the best of all being that made from a wick of papyrus mixed with oil of sesame; the soot being removed with a feather and caught in a new vessel prepared for the purpose. This mixture, too, is very efficacious for preventing superfluous eyelashes from growing again when once pulled out.

Bull's gall is made up into eye-salves with white of egg, these salves being steeped in water and applied to the eyes for four days successively. Veal suet, with goose-grease and the extracted juice of ocimum, is remarkably good for diseases of the eye-lids. Veal marrow, with the addition of an equal proportion of wax and oil or oil of roses, an egg being added to the mixture, is used as a liniment for indurations of the eyelids. Soft goats' milk cheese is used as an application, with warm water, to allay defluxions of the eyes; but when they are attended with swelling, honey is used instead of the water. In both cases, however, the eyes should be fomented with warm whey. In cases of dry ophthalmia, it is found a very useful plan to take the muscles lying within a loin of pork, and, after reducing them to ashes, to pound and apply them to the part affected.

She-goats, they say, are never affected with ophthalmia, from the circumstance that they browse upon certain kinds of herbs: the same, too, with the gazelle. Hence it is that we find it recommended, at the time of new moon, to swallow the dung of these animals, coated with wax. As they are able to see, too, by night, it is a general belief that the blood of a hegoat is a cure for those persons affected with dimness of sight to whom the Greeks have given the name of "nyctalopes." A similar virtue is attributed to the liver of a she-goat, boiled in astringent wine. Some are in the habit of rubbing the eyes with the thick gravy which exudes from a she-goat's liver roasted, or with the gall of that animal: they recommend the flesh also as a diet, and say that the

patient should expose his eyes to the fumes of it while boiling: it is a general opinion, too, that the animal should be of a reddish colour. Another prescription is, to fumigate the eyes with the steam arising from the liver boiled in an earthen jar, or, according to some authorities, roasted.

Goats' gall is applied for numerous purposes: with honey, for films upon the eyes; with one-third part of white hellebore, for cataract; with wine, for spots upon the eyes, indurations of the cornea, films, webs, and argema; with extracted juice of cabbage, for diseases of the eyelids, the hairs being first pulled out, and the preparation left to dry on the parts affected; and with woman's milk, for rupture of the coats of the eye. For all these purposes, the gall is considered the most efficacious, when dried. Nor is the dung of this animal held in disesteem, being applied with honey for defluxions of the eyes. The marrow, too, of a goat, or a hare's lights, we find used for pains in the eyes; and the gall of a goat, with raisin wine or honey, for the dispersion of films upon those organs. It is recommended also, for ophthalmia, to anoint the eyes with wolf's fat or swine's marrow: we find it asserted, too, that persons who carry a wolf's tongue, inserted in a bracelet, will always be exempt from ophthalmia.

Detailed table of contents

CHAP. 48.

REMEDIES FOR DISEASES AND AFFECTIONS OF THE EARS.

Pains and diseases of the ears are cured by using the urine of a wild boar, kept in a glass vessel, or the gall of a wild boar, swine, or ox, mixed with castor-oil and oil of roses in equal proportions. But the best remedy of all is bull's gall, warmed with leek juice, or with honey, if there is any suppuration. Bull's gall too, warmed by itself in a pomegranate rind, is an excellent remedy for offensive exhalations from the ears: in combination with woman's milk, it is efficacious as a cure for ruptures of those organs. Some persons are of opinion that it is a good plan to wash the ears with this preparation in cases where the hearing is affected; while others again, after washing the ears with warm water, insert a mixture composed of the old slough of a serpent and vinegar, wrapped up in a dossil of wool. In cases, however, where the deafness is very considerable, gall warmed in a pomegranate rind with myrrh and rue, is injected into the ears; sometimes, also, fat bacon is used for this purpose, or fresh asses' dung, mixed with oil of roses: in all cases, however, the ingredients should be warmed.

The foam from a horse's mouth is better still, or the ashes of fresh horse dung, mixed with oil of roses: fresh butter too is good; beef-suet mixed with goose-grease; the urine of a bull or she-goat; or fullers' lant, heated to such a degree that the steam escapes by the neck of the vessel. For this purpose also, one third part of vinegar is mixed with a small portion of the urine of a calf, which has not begun to graze. They apply also to the ears calf's dung, mixed with the gall of that animal and sloughs of serpents, care being taken to warm the ears before the application, and all the remedies being wrapped in wool. Veal-suet, too, is used, with goose-grease and extract of ocimum; or else veal marrow, mixed with bruised cummin and injected into the ears. For pains in the ears, the liquid ejected by a boar in copulation is used, due care being taken to receive it before it falls to the ground. For fractures of the ears, a glutinous composition is made from the genitals of a calf, which is dissolved in water when used; and for other diseases of those organs, foxes' fat is employed, goat's gall mixed with rose-oil warmed, or else extracted juice of leeks: in all cases where there is any rupture, these preparations are used in combination with woman's milk. Where a patient is suffering from hardness of hearing, ox-gall is employed, with the urine of a he or she-goat; the same, too, where there is any suppuration.

Whatever the purpose for which they are wanted, it is the general opinion that these substances are more efficacious when they have been smoked in a goat's horn for twenty days. Hare's rennet, too, is highly spoken of, taken in Aminean wine, in the proportion of one third of a denarius of rennet to one half of a denarius of sacopenum. Bears' grease, mixed with equal proportions

of wax and bull-suet, is a cure for imposthumes of the parotid glands: some persons add hypocisthis to the composition, or else content themselves with employing butter only, after first fomenting the parts affected with a decoction of fenugreek, the good effects of which are augmented by strychnos. The testes, too, of the fox, are very useful for this purpose; as also bull's blood, dried and reduced to powder. She-goats' urine, made warm, is used as an injection for the ears; and a liniment is made of the dung of those animals, in combination with axle-grease.

Detailed table of contents

CHAP. 49.

REMEDIES FOR TOOTH-ACHE.

The ashes of deer's horns strengthen loose teeth and allay tooth-ache, used either as a friction or as a gargle. Some persons, however, are of opinion that the horn, unburnt and reduced to powder, is still more efficacious for all these purposes. Dentifrices are made both from the powder and the ashes. Another excellent remedy is a wolf's head, reduced to ashes: it is a well-known fact, too, that there are bones generally found in the excrements of that animal; these bones, attached to the body as an amulet, are productive of advantageous effects. For the cure of tooth-ache, hare's rennet is injected into the ear: the head also of that animal, reduced to ashes, is used in the form of a dentifrice, and, with the addition of nard, is a corrective of bad breath. Some persons, however, think it a better plan to mix the ashes of a mouse's head with the dentifrice. In the side of the hare there is a bone found, similar to a needle in appearance: for the cure of tooth-ache it is recommended to scarify the gums with this bone. The pastern-bone of an ox, ignited and applied to loose teeth which ache, has the effect of strengthening them in the sockets; the same bone, reduced to ashes, and mixed with myrrh, is also used as a dentifrice. The ashes of burnt pig's feet are productive of a similar effect, as also the calcined bones of the cotyloid cavities in which the hip-bones move. It is a well-known fact, that, introduced into the throat of beasts of burden, these bones are a cure for worms, and that, in a calcined state, they are good for strengthening the teeth.

When the teeth have been loosened by a blow, they are strengthened by using asses' milk, or else ashes of the burnt teeth of that animal, or a horse's lichen, reduced to powder, and injected into the ear with oil. By lichen I do not mean the hippomanes, a noxious substance which I purposely forbear to enlarge upon, but an excrescence which forms upon the knees of horses, and just above the hoofs. In the heart of this animal there is also found a bone which bears a close resemblance to the eye-teeth of a dog: if the gums are scarified with this bone, or with a tooth taken from the jaw-bone of a dead horse, corresponding in place with the tooth affected, the pain will be removed, they say. Anaxilaüs assures us that if the liquid which exudes from a mare when covered, is ignited on the wick of a lamp, it will give out a most marvellous representation of horses' heads; and the same with reference to the she-ass. As to the hippomanes, it is possessed of properties so virulent and so truly magical, that if it is only thrown into fused metal which is being cast into the resemblance of an Olympian mare, it will excite in all stallions that approach it a perfect frenzy for copulation.

Another remedy for diseases of the teeth is joiners' glue, boiled in water and applied, care being taken to remove it very speedily, and instantly to rinse

the teeth with wine in which sweet pomegranate-rind has been boiled. It is, considered, also, a very efficacious remedy to wash the teeth with goats' milk, or bull's gall. The pastern-bones of a she-goat just killed, reduced to ashes, and indeed, to avoid the necessity for repetition, of any other four-footed beast reared in the farmyard, are considered to make an excellent dentifrice.

Detailed table of contents

CHAP. 50. (12.)

REMEDIES FOR DISEASES OF THE FACE.

It is generally believed that asses' milk effaces wrinkles in the face, renders the skin more delicate, and preserves its whiteness: and it is a well-known fact, that some women are in the habit of washing their face with it seven hundred times daily, strictly observing that number. Poppæa, the wife of the Emperor Nero, was the first to practise this; indeed, she had sitting-baths, prepared solely with asses' milk, for which purpose whole troops of she-asses used to attend her on her journies. Purulent eruptions on the face are removed by an application of butter, but white lead, mixed with the butter, is an improvement. Pure butter, alone, is used for serpiginous eruptions of the face, a layer of barley-meal being powdered over it. The caul of a cow that has just calved, is applied, while still moist, to ulcers of the face.

The following recipe may seem frivolous, but still, to please the women, it must not be omitted; the pastern-bone of a white steer, they say, boiled forty days and forty nights, till it is quite dissolved, and then applied to the face in a linen cloth, will remove wrinkles and preserve the whiteness of the skin. An application of bull's dung, they say, will impart a rosy tint to the cheeks, and not crocodilea even is better for the purpose; the face, however, must be washed with cold water, both before and after the application. Sun-burns and all other discolorations of the skin, are removed by the aid of calves' dung kneaded up by hand with oil and gum; ulcerations and chaps of the mouth, by an application of veal or beef-suet, mixed with goose-grease and juice of ocimum. There is another composition, also, made of veal-suet with stag's marrow and leaves of white-thorn, the whole beaten up together. Marrow, too, mixed with resin, even if it be cow marrow only, is equally good; and the broth of cow-beef is productive of similar effects. A most excellent remedy for lichens on the face is a glutinous substance prepared from the genitals of a male calf, melted with vinegar and live sulphur, and stirred together with the branch of a fig-tree: this composition is applied twice a day, and should be used quite fresh. This glue, similarly prepared from a decoction of honey and vinegar, is a cure for leprous spots, which are also removed by applying a he-goat's liver warm.

Elephantiasis, too, is removed by an application of goats' gall; and leprous spots and furfuraceous eruptions by employing bull's gall with the addition of nitre, or else asses' urine about the rising of the Dog-star. Spots on the face are removed by either bull's gall or ass's gall diluted in water by itself, care being taken to avoid the sun or wind after the skin has peeled off. A similar effect is produced, also, by using bull's gall or calf's gall, in combination with seed of cunila and the ashes of a deer's horn, burnt at the rising of Canicula.

Asses' fat, in particular, restores the natural colour to scars and spots on the

skin caused by lichen or leprosy. A he-goat's gall, mixed with cheese, live sulphur, and sponge reduced to ashes, effectually removes freckles, the composition being brought to the consistency of honey before being applied. Some persons, however, prefer using dried gall, and mix with it warm bran, in the proportion of one obolus to four oboli of honey, the spots being rubbed briskly first. He-goat suet, too, is highly efficacious, used in combination with gith, sulphur, and iris; this mixture being also employed, with goose-grease, stag's marrow, resin, and lime, for the cure of cracked lips. I find it stated by certain authors, that persons who have freckles on the skin are looked upon as disqualified from taking any part in the sacrifices prescribed by the magic art.

Detailed table of contents

CHAP. 51.

REMEDIES FOR DISEASES OF THE TONSILLARY GLANDS, AND FOR SCROFULA.

Cow's milk or goat's milk is good for ulcerations of the tonsillary glands and of the trachea. It is used in the form of a gargle, warm from the udder or heated, goat's milk being the best, boiled with mallows and a little salt. A broth made from tripe is an excellent gargle for ulcerations of the tongue and trachea; and for diseases of the tonsillary glands, the kidneys of a fox are considered a sovereign remedy, dried and beaten up with honey, and applied externally. For quinzey, bull's gall or goat's gall is used, mixed with honey. A badger's liver, taken in water, is good for offensive breath, and butter has a healing effect upon ulcerations of the mouth. When a pointed or other substance has stuck in the throat, by rubbing it externally with cats' dung, the substance, they say, will either come up again or pass downwards into the stomach.

Scrofulous sores are dispersed by applying the gall of a wild boar or of an ox, warmed for the purpose: but it is only when the sores are ulcerated that hare's rennet is used, applied in a linen cloth with wine. The ashes of the burnt hoof of an ass or horse, applied with oil or water, is good for dispersing scrofulous sores; warmed urine also; the ashes of an ox's hoof, taken in water; cow-dung, applied hot with vinegar; goat-suet with lime; goats' dung, boiled in vinegar; or the testes of a fox. Soap, too, is very useful for this purpose, an invention of the Gauls for giving a reddish tint to the hair. This substance is prepared from tallow and ashes, the best ashes for the purpose being those of the beech and yoke-elm: there are two kinds of it, the hard soap and the liquid, both of them much used by the people of Germany, the men, in particular, more than the women.

Detailed table of contents

CHAP. 52

REMEDIES FOR PAINS IN THE NECK.

For pains in the neck, the part should be well rubbed with butter or bears' grease; and for a stiff neck, with beef suet, a substance which, in combination with oil, is very useful for the cure of scrofula. For the painful cramp, attended with inflexibility, to which people give the name of "opisthotony," the urine of a she-goat, injected into the ears, is found very useful; as also a liniment made of the dung of that animal, mixed with bulbs. In cases where the nails have been crushed, it is an excellent plan to attach to them the gall of any kind of animal. Whitlows upon the fingers should be treated with dried bull's gall, dissolved in warm water. Some persons are in the habit of adding sulphur and alum, of each an equal weight.

Detailed table of contents

CHAP. 53.

-REMEDIES FOR COUGH AND FOR SPITTING OF BLOOD.

A. wolf's liver, administered in mulled wine, is a cure for cough; a bear's gall also, mixed with honey; the ashes of the tips of a cow's horn; or else the saliva of a horse, taken in the drink for three consecutive days — in which last case the horse will be sure to die, they say. A deer's lights are useful for the same purpose, dried with the gullet of the animal in the smoke, and then beaten up with honey, and taken daily as an electuary: the spitter deer, be it remarked, is the kind that is the most efficacious for the purpose.

Spitting of blood is cured by taking ashes of burnt deer's horns, or else a hare's rennet in drink, in doses of one-third of a denarius, with Samian earth and myrtle-wine. The dung of this last animal, reduced to ashes and taken in the evening, with wine, is good for coughs that are recurrent at night. The smoke, too, of a hare's fur, inhaled, has the effect of bringing off from the lungs such humours as are difficult to be discharged by expectoration. Purulent ulcerations of the chest and lungs, and bad breath proceeding from a morbid state of the lungs, are successfully treated with butter boiled with an equal quantity of Attic honey till it assumes a reddish hue, a spoonful of the mixture being taken by the patient every morning: some persons, however, instead of honey prefer using larch-resin for the purpose. In cases where there are discharges of blood, cow's blood, they say, is good, taken in small quantities with vinegar; but as to bull's blood, it would be a rash thing to believe in any such recommendation. For inveterate spitting of blood, bull-glue is taken, in doses of three oboli, in warm water.

Detailed table of contents

CHAP. 54. (13.)

REMEDIES FOR AFFECTIONS OF THE STOMACH.

Ulcerations of the stomach are effectually treated with asses' milk or cows' milk. For gnawing pains in that region, beef is stewed, with vinegar and wine. Fluxes are healed by taking the ashes of burnt deer's horns; and discharges of blood by drinking the blood of a kid just killed, made hot, in doses of three cyathi, with equal proportions of vinegar and tart wine; or else by taking kid's rennet, with twice the quantity of vinegar.

Detailed table of contents

CHAP. 55.

REMEDIES FOR LIVER COMPLAINTS AND FOR ASTHMA.

Liver complaints are cured by taking a wolf's liver dried, in honied wine; or by using the dried liver of an ass, with twice the quantity of rock-parsley and three nuts, the whole beaten up with honey and taken with the food. The blood, too, of a he-goat is prepared and taken with the food. For persons suffering from asthma, the most efficient remedy of all is the blood of wild horses taken in drink; and next to that, asses' milk boiled with bulbs, the whey being the part used, with the addition of nasturtium steeped in water and tempered with honey, in the proportion of one cyathus of nasturtium to three semi-sextarii of whey. The liver or lights of a fox, taken in red wine, or bear's gall in water, facilitate the respiration.

Detailed table of contents

CHAP. 56.

REMEDIES FOR PAINS IN THE LOINS.

For pains in the loins and all other affections which require emollients, frictions with bears' grease should be used; or else ashes of stale boars' dung or swine's dung should be mixed with wine and given to the patients. The magicians, too, have added to this branch of medicine their own fanciful devices. In the first place of all, madness in he-goats, they say, may be effectually calmed by stroking the beard; and if the beard is cut off, the goat will never stray to another flock,

To the above composition they add goats' dung, and recommend it to be held in the hollow of the hand, as hot as possible, a greased linen cloth being placed beneath, and care being taken to hold it in the right hand if the pain is on the left side, and in the left hand if the pain is on the right. They recommend also that the dung employed for this purpose should be taken up on the point of a needle made of copper. The mode of treatment is, for the patient to hold the mixture in his hand till the heat is felt to have penetrated to the loins, after which the hand is rubbed with a pounded leek, and the loins with the same dung annealed with honey. They prescribe also for the same malady the testes of a hare, to be eaten by the patient. In cases of sciatica they are for applying cow-dung warmed upon hot ashes in leaves: and for pains in the kidneys they recommend a hare's kidneys to be swallowed raw, or perhaps boiled, but without letting them be touched by the teeth. If a person carries about him the pastern-bone of a hare, he will never be troubled with pains in the bowels, they say.

[Detailed table of contents](#)

CHAP. 57.

REMEDIES FOR AFFECTIONS OF THE SPLEEN.

Affections of the spleen are alleviated by taking the gall of a wild boar or hog in drink; ashes of burnt deer's horns in vinegar; or, what is best of all, the dried spleen of an ass, the good effects being sure to be felt in the course of three days. The first dung voided by an ass's foal—a substance known as “polea” by the people of Syria — is administered in oxymel for these complaints; a dried horse tongue, too, is taken in wine, a sovereign remedy which, Cæcilius Bion tells us, he first heard of when living among the barbarous nations. The milt of a cow or ox is used in a similar manner; but when it is quite fresh, the practice is to roast or boil it and take it with the food. For pains in the liver a topical application is made by bruising twenty heads of garlick in one sextarius of vinegar, and applying them in a piece of ox bladder. For the same malady the magicians recommend a calf's milt, bought at the price set upon it and without any haggling, that being an important point, and one that should be religiously observed. This done, the milt must be cut in two lengthwise, and attached to the patient's shirt, on either side; after which, the patient must put it on and let the pieces fall at his feet, and must then pick them up, and dry them in the shade. While this last is doing, the diseased liver of the patient will gradually contract, they say, and he will eventually be cured. The lights, too, of a fox are very useful for this purpose, dried on hot ashes and taken in water; the same, too, with a kid's milt, applied to the part affected.

Detailed table of contents

CHAP. 58. (14.)

REMEDIES FOR BOWEL COMPLAINTS.

To arrest looseness of the bowels, deer's blood is used; the ashes also of deer's horns; the liver of a wild boar, taken fresh and without salt, in wine; a swine's liver roasted, or that of a he-goat, boiled in five semisextarii of wine; a hare's rennet boiled, in quantities the size of a chick-pea, in wine, or, if there are symptoms of fever, in water. To this last some persons add nut-galls, while others, again, content themselves with hare's blood boiled by itself in milk. Ashes; too, of burnt horse-dung are taken in water for this purpose; or else ashes of the part of an old bull's horn which lies nearest the root, sprinkled in water; the blood, too, of a he-goat boiled upon charcoal; or a decoction made from a goat's hide boiled with the hair on.

For relaxing the bowels a horse's rennet is used, or else the blood, marrow, or liver of a she-goat. A similar effect is produced by applying a wolf's gall to the navel, with elaterium; by taking mares' milk, goats' milk with salt and honey, or a she-goat's gall with juice of cyclaminos, and a little alum — in which last case some prefer adding nitre and water to the mixture. Bull's gall, too, is used for a similar purpose, beaten up with wormwood and applied in the form of a suppository; or butter is taken, in considerable doses.

Cœliac affections and dysentery are cured by taking cow's liver; ashes of deer's horns, a pinch in three fingers swallowed in water; hare's rennet, kneaded up in bread, or, if there is any discharge of blood, taken with polenta; or else boar's dung, swine's dung, or hare's dung, reduced to ashes and mixed with mulled wine. Among the remedies, also, for the cœliac flux and dysentery, veal broth is reckoned, a remedy very commonly used. If the patient takes asses' milk for these complaints, it will be all the better if honey is added; and no less efficacious for either complaint are the ashes of asses' dung taken in wine; or else polea, the substance above-mentioned. In such cases, even when attended with a discharge of blood, we find a horse's rennet recommended, by some persons known as "hippace;" ashes of burnt horse-dung; horses' teeth pounded; and boiled cows' milk. In cases of dysentery, it is recommended to add a little honey; and, for the cure of griping pains, ashes of deer's horns, bull's gall mixed with cum-min, or the flesh of a gourd, should be applied to the navel. For both complaints new cheese made of cows' milk is used, as an injection; butter also, in the proportion of four semisextarii to two ounces of turpentine, or else employed with a decoction of mallows or with oil of roses. Veal-suet or beef-suet is also given, and the marrow of those animals is boiled with meal, a little wax, and some oil, so as to form a sort of pottage. This marrow, too, is kneaded up with bread for a similar purpose; or else goats' milk is used, boiled down to one half. In cases, too, where there are gripings in the bowels, wine of the first running is

administered. For the last-named pains, some persons are of opinion that it is a sufficient remedy to take a single dose of hare's rennet in mulled wine; though others again, who are more distrustful, are in the habit of applying a liniment to the abdomen, made of goats' blood, barley-meal, and resin.

For all defluxions of the bowels it is recommended to apply soft cheese, and for cœliac affections and dysentery old cheese, powdered, one cyathus of cheese being taken in three cyathi of ordinary wine. Goats' blood is boiled down with the marrow of those animals for the cure of dysentery; and the cœliac flux is effectually treated with the roasted liver of a she-goat, or, what is still better, the liver of a he-goat boiled in astringent wine, and administered in the drink, or else applied to the navel with oil of myrtle. Some persons boil down the liver in three sextarii of water to half a sextarius, and then add rue to it. The milt of a he or she-goat is sometimes roasted for this purpose, or the suet of a he-goat is incorporated in bread baked upon the ashes; the fat, too, of a she-goat, taken from the kidneys more particularly, is used. This last, however, must be taken by itself and swallowed immediately, being generally recommended to be taken in water moderately cool. Some persons, too, boil goats' suet in water, with a mixture of polenta, cummin, anise, and vinegar; and for the cure of cœliac affections, they rub the abdomen with a decoction of goats' dung and honey.

For both the cœliac flux and dysentery, kid's rennet is employed, taken in myrtle wine in pieces the size of a bean, or else kid's blood, prepared in the form of a dish known by the name of "sanguiculus." For dysentery an injection is employed, made of bull glue dissolved in warm water. Flatulency is dispelled by a decoction of calf's dung in wine. For intestinal affections deer's rennet is highly recommended, boiled with beef and lentils, and taken with the food; hare's fur, also reduced to ashes and boiled with honey; or boiled goat's milk, taken with a small quantity of mallows and some salt; if rennet is added, the remedy will be all the more effectual. Goat suet, taken in any kind of broth, is possessed of similar virtues, care being taken to swallow cold water immediately after. The ashes of a kid's thighs are said to be marvellously efficacious for intestinal hernia; as also hare's dung, boiled with honey, and taken daily in pieces the size of a bean; indeed, these remedies are said to have proved effectual in cases where a cure has been quite despaired of. The broth too, made from a goat's head, boiled with the hair on, is highly recommended.

CHAP. 59.

REMEDES FOR TENESMUS, TAPEWORM, AND AFFECTIONS OF THE COLON.

The disease called “tenesmus,” or in other words, a frequent and ineffectual desire to go to stool, is removed by drinking asses’ milk or cows’ milk. The various kinds of tapeworm are expelled by taking the ashes of deer’s horns in drink. The bones which we have spoken of as being found in the excrements of the wolf, worn attached to the arm, are curative of diseases of the colon, provided they have not been allowed to touch the ground. Polea, too, a substance already mentioned, is remarkably useful for this purpose, boiled in grape juice: the same too with swine’s dung, powdered and mixed with cummin, in a decoction of rue. The antler of a young stag, reduced to ashes and taken in wine, mixed with African snails, crushed with the shells on, is considered a very, useful remedy.

CHAP. 60. (15.)

-REMEDIES FOR AFFECTIONS OF THE BLADDER, AND FOR URINARY CALCULI.

Diseases of the bladder, and the torments attendant upon calculi, are treated with the urine of a wild boar, or the bladder of that animal taken as food; both of them being still more efficacious if they have been thoroughly soaked first. The bladder, when eaten, should be boiled first, and if the patient is a female, it should be a sow's bladder. There are found in the liver of the wild boar certain small stones, or what in hardness resemble small stones, of a white hue, and resembling those found in the liver of the common swine: if these stones are pounded and taken in wine, they will expel calculi, it is said. So oppressed is the wild boar by the burden of his urine, that if he has not first voided it, he is unable to take to flight, and suffers himself to be taken as though he were enchained to the spot. This urine, they say, has a consuming effect upon urinary calculi. The kidneys of a hare, dried and taken in wine, act as an expellent upon calculi. We have already mentioned that in the gammon of the hog there are certain joint-bones; a decoction made from them is remarkably useful for urinary affections. The kidneys of an ass, dried and pounded, and administered in undiluted wine, are a cure for diseases of the bladder. The excrescences that grow on horses' legs, taken for forty days in ordinary wine or honied wine, expel urinary calculi. The ashes, too, of a horse's hoof, taken in wine or water, are considered highly useful for this purpose; and the same with the dung of a she-goat — if a wild goat, all the better — taken in honied wine: goats' hair, too, is used, reduced to ashes.

For carbuncles upon the generative organs, the brains and blood of a wild boar or swine are highly recommended: and for serpiginous affections of those parts, the liver of those animals is used, burnt upon juniper wood more particularly, and mixed with papyrus and arsenic; the ashes, also, of their dung; ox-gall, kneaded to the consistency of honey, with Egyptian alum and myrrh, beet-root boiled in wine being laid upon it; or else beef. Running ulcers of those parts are treated with veal-suet and marrow, boiled in wine, or with the gall of a she-goat, mixed with honey and the extracted juice of the bramble. In cases where these ulcers are serpiginous, it is recommended to use goats' dung with honey or vinegar, or else butter by itself. Swellings of the testes are reduced by using veal-suet with nitre, or the dung of the animal boiled in vinegar. The bladder of a wild boar, eaten roasted, acts as a check upon incontinence of urine; a similar effect being produced by the ashes of the feet of a wild boar or swine sprinkled in the drink; the ashes of a sow's bladder taken in drink; the bladder or lights of a kid; a hare's brains taken in wine; the testes of a male hare grilled; the rennet of that animal taken with goose-grease and polenta; or the kidneys of an ass, beaten up and taken in undiluted wine.

The magicians tell us, that after taking the ashes of a boar's genitals in sweet wine, the patient must make water in a dog kennel, and repeat the following formula— "This I do that I may not wet my bed as a dog does." On the other hand, a swine's bladder, attached to the groin, facilitates the discharge of the urine, provided it has not already touched the ground.

Detailed table of contents

CHAP. 61.

REMEDIES FOR DISEASES OF THE GENERATIVE ORGANS AND OF THE FUNDAMENT.

For diseases of the fundament, a sovereign remedy is bear's gall, mixed with the grease; to which some persons are in the habit of adding litharge and frankincense. Butter, too, is very good, employed with goose-grease and oil of roses. The proportions in which they are mixed will be regulated by the circumstances of the case, care being taken to see that they are of a consistency which admits of their being easily applied. Bull's gall upon lint is a remarkably useful remedy, and has the effect of making chaps of the fundament cicatrize with great rapidity. Swellings of those parts are treated with veal suet — that from the loins in particular — mixed with rue. For other affections, goats' blood is used, with polenta. Goats' gall, too, is employed by itself, for the cure of condylomata, and sometimes, wolf's gall, mixed with wine.

Bears' blood is curative of inflamed tumours and apostemes upon these parts in general; as also bulls' blood, dried and powdered. The best remedy, however, is considered to be the stone which the wild ass voids with his urine, it is said, at the moment he is killed. This stone, which is in a somewhat liquefied state at first, becomes solid when it reaches the ground: attached to the thigh, it; disperses all collections of humours and all kinds of suppurations: it is but rarely found, however, and it is not every wild ass that produces it, but as a remedy it is held in high esteem. Asses' urine too, used in combination with gith, is highly recommended; the ashes of a horse's hoof, applied with oil and water; a horse's blood, that of a stone-horse in particular; the blood, also, of an ox or cow, or the gall of those animals. Their flesh too, applied warm, is productive of similar results; the hoofs reduced to ashes, and taken in water or honey; the urine of a she-goat; the flesh of a he-goat, boiled in water; the dung of these animals, boiled with honey; or else a boar's gall, or swine's urine, applied in wool.

Riding on horseback, we well know, galls and chafes the inside of the thighs: the best remedy for accidents of this nature is to rub the parts with the foam which collects at a horse's mouth. Where there are swellings in the groin, arising from ulcers, a cure is effected by inserting in the sores three horse-hairs, tied with as many knots.

[Detailed table of contents](#)

CHAP. 62. (16.)

REMEDIES FOR GOUT AND FOR DISEASES OF THE FEET.

For the cure of gout, bears' grease is employed, mixed in equal proportions with bull-suet and wax; some persons add to the composition, hypocisthis and nut-galls. Others, again, prefer he-goat suet, mixed with the dung of a she-goat and saffron, or else with mustard, or sprigs of ivy pounded and used with perdicium, or with flowers of wild cucumber. Cowdung is also used, with lees of vinegar. Some persons speak highly in praise of the dung of a calf which has not begun to graze, or else a bull's blood, without any other addition; a *fox*, also, boiled alive till only the bones are left; a wolf boiled alive in oil to the consistency of a cerate; he-goat suet, with an equal proportion of helxine, and one-third part of mustard; or ashes of goats' dung, mixed with axle-grease. They say, too, that for sciatica, it is an excellent plan to apply this dung boiling hot beneath the great toes; and that, for diseases of the joints, it is highly efficacious to attach bears' gall or hares' feet to the part affected. Gout, they say, may be allayed by the patient always carrying about with him a hare's foot, cut off from the animal alive.

Bears' grease is a cure for chilblains and all kinds of chaps upon the feet; with the addition of alum, it is still more efficacious. The same results are produced by using goat-suet; a horse's teeth powdered; the gall of a wild boar or hog; or else the lights of those animals, applied with their grease; and this, too, where the soles are blistered, or the feet have been crushed by a substance striking against them. In cases where the feet have been frozen, ashes of burnt hare's fur are used; and for contusions of the feet, the lights of that animal are applied, sliced or reduced to ashes. Blisters occasioned by the sun are most effectually treated by using asses' fat, or else beef-suet, with oil of roses. Corns, chaps, and callosities of the feet are cured by the application of wild boars' dung or swine's dung, used fresh, and removed at the end of a couple of days. The pastern-bones of these animals are also used, reduced to ashes; or else the lights of a wild boar, swine, or deer. When the feet have been galled by the shoes, they are rubbed with the urine of an ass, applied with the mud formed by it upon the ground. Corns are treated with beef-suet and powdered frankincense; chilblains with burnt leather, that of an old shoe, in particular; and injuries produced by tight shoes with ashes of goat-skin, tempered with oil.

The pains attendant upon varicose veins are mitigated by using ashes of burnt calves' dung, boiled with lily roots and a little honey: a composition which is equally good for all kinds of inflammations and sores that tend to suppurate. It is very useful, also, for gout and diseases of the joints, when it is the dung of a bull-calf that is used more particularly. For excoriations of the joints, the gall of a wild boar or swine is applied, in a warm linen cloth: the

dung, also, of a calf that has not begun to graze; or else goat-dung, boiled in vinegar with honey. Veal-suet rectifies malformed nails, as also goat-suet, mixed with sandarach. Warts are removed by applying ashes of burnt calves' dung in vinegar, or else the mud formed upon the ground by the urine of an ass.

[Detailed table of contents](#)

CHAP. 63.

REMEDIES FOR EPILEPSY.

In cases of epilepsy, it is a good plan to eat a bear's testes, or those of a wild boar, with mares' milk or water; or else to drink a wild boar's urine with honey and vinegar, that being the best which has been left to dry in the bladder. The testes, also, of swine are prescribed, dried and beaten up in sows' milk, the patient abstaining from wine some days before and after taking the mixture. The lights of a hare, too, are recommended, salted, and taken with one third of frankincense, for thirty consecutive days, in white wine: hare's rennet also and asses' brains, smoked with burning leaves, and administered in hydromel, in doses of half an ounce per day. An ass's hoofs are reduced to ashes, and taken for a month together, in doses of two spoonfuls; the testes, also, of an ass, salted and mixed with the drink, asses' milk or water in particular. The secundines, also, of a she-ass are recommended, more particularly when it is a male that has been foaled: placed beneath the nostrils of the patient, when the fits are likely to come on, this substance will effectually repel them.

There are some persons who recommend the patient to eat the heart of a black he-ass in the open air with bread, upon the first or second day of the moon: others, again, prescribe the flesh of that animal, and others the blood, diluted with vinegar, and taken for forty days together. Some mix horse-stale for this purpose, with smithy water fresh from the forge, employing the same mixture for the cure of delirium. Epilepsy is also treated with mares' milk, or the excrescences from a horse's legs, taken in honey and vinegar. The magicians highly recommend goats' flesh, grilled upon a funeral pile; as also the suet of that animal, boiled with an equal quantity of bull's gall, and kept in the gall-bladder; care being taken not to let it touch the ground, and the patient swallowing it in water, standing aloft. The smell arising from a goat's horns or deer's antlers, burnt, efficiently detects the presence of epilepsy.

In cases where persons are suddenly paralyzed, the urine of an ass's foal, applied to the body with nard, is very useful, it is

Detailed table of contents

CHAP. 64.

REMEDIES FOR JAUNDICE.

For the cure of jaundice, the ashes of a stag's antlers are employed; or the blood of an ass's foal, taken in wine. The first dung, too, that has been voided by the foal after its birth, taken in wine, in pieces the size of a bean, will effect a cure by the end of three days. The dung of a new-born colt is possessed of a similar efficacy.

[Detailed table of contents](#)

CHAP. 65.

-REMEDIES FOR BROKEN BONES.

For broken bones, a sovereign remedy is the ashes of the jaw-bone of a wild boar or swine: boiled bacon, too, tied round the broken bone, unites it with marvellous rapidity. For fractures of the ribs, goats' dung, applied in old wine, is extolled as the grand remedy, being possessed in a high degree of aperient, extractive, and healing properties.

Detailed table of contents

CHAP. 66.

REMEDIES FOR FEVERS.

Deer's flesh, as already stated, is a febrifuge. Periodical and recurrent fevers are cured, if we are to believe what the magicians tell us, by wearing the right eye of a wolf, salted, and attached as an amulet. There is one kind of fever generally known as "amphemerine" it is to be cured, they say, by the patient taking three drops of blood from an ass's ear, and swallowing them in two semi-sextarii of water. For quartan fever, the magicians recommend cats' dung to be attached to the body, with the toe of a horned owl, and, that the fever may not be recurrent, not to be removed until the seventh paroxysm is past. Who, pray, could have ever made such a discovery as this? And what, too, can be the meaning of this combination? Why, of all things in the world, was the toe of a horned owl made choice of?

Other adepts in this art, who are more moderate in their suggestions, recommend for quartan fever, the salted liver of a cat that has been killed while the moon was on the wane, to be taken in wine just before the paroxysms come on. The magicians recommend, too, that the toes of the patient should be rubbed with the ashes of burnt cow-dung, diluted with a boy's urine, and that a hare's heart should be attached to the hands; they prescribe, also, hare's rennet, to be taken in drink just before the paroxysms come on. New goats' milk cheese is also given with honey, the whey being carefully extracted first.

Detailed table of contents

CHAP. 67. (17.)

REMEDIES FOR MELANCHOLY, LETHARGY, AND PHTHISIS.

For patients affected with melancholy, calves' dung, boiled in wine, is a very useful remedy. Persons are aroused from lethargy by applying to the nostrils the callosities from an ass's legs steeped in vinegar, or the fumes of burnt goats' horns or hair, or by the application of a wild boar's liver: a remedy which is also used for confirmed drowsiness.

The cure of phthisis is effected by taking a wolf's liver boiled in thin wine; the bacon of a sow that has been fed upon herbs; or the flesh of a she-ass, eaten with the broth: this last mode in particular, being the one that is employed by the people of Achaia. They say too, that the smoke of dried cow-dung — that of the animal when grazing, I mean—is remarkably good for phthisis, inhaled through a reed; and we find it stated that the tips of cows' horns are burnt, and administered with honey, in doses of two spoonfuls, in the form of pills. Goat suet, many persons say, taken in a pottage of alica, or melted fresh with honied wine, in the proportion of one ounce of suet to one cyathus of wine, is good for cough and phthisis, care being taken to stir the mixture with a sprig of rue. One author of credit assures us that before now, a patient whose recovery has been despaired of; has been restored to health by taking one cyathus of wild goat suet and an equal quantity of milk. Some writers, too, have stated that ashes of burnt swine's dung are very useful, mixed with raisin wine; as also the lights of a deer, a spitter deer in particular, smoke-dried and beaten up in wine.

Detailed table of contents

CHAP. 68.

REMEDIES FOR DROPSY.

For dropsy, a will boar's urine is good, taken in small doses in the patient's drink; it is of much greater efficacy, however, when it has been left to dry in the bladder of the animal. The ashes, too, of burnt cow-dung, and of bulls' dung in particular — animals that are reared in herds, I mean — are highly esteemed. This dung, the name given to which is "bolbiton," is reduced to ashes, and taken in doses of three spoonfuls to one semisextarius of honied wine; that of the female animal being used where the patient is a woman, and that of the other sex in the case of males; a distinction about which the magicians have made a sort of grand mystery. The dung of a bull-calf is also applied topically for this disease, and ashes of burnt calves' dung are taken with seed of staphylinos, in equal proportions, in wine. Goats' blood also is used, with the marrow; but it is generally thought that the blood of the he-goat is the most efficacious, when the animal has fed upon lentisk, more particularly.

Detailed table of contents

CHAP. 69.

REMEDIES FOR ERYSIPELAS, AND FOR PURULENT ERUPTIONS.

For erysipelas a liniment of bears' grease is used, that from the kidneys in particular; fresh calves' dung also, or cow-dung; dried goats' milk cheese, with leeks; or else the fine scrapings of a deer's skin, brought off with pumice-stone and beaten up in vinegar. Where there is redness of the skin attended with itching, the foam from a horse's mouth is used, or the hoof, reduced to ashes.

For the cure of purulent eruptions ashes of burnt asses' dung are applied, with butter; and for the removal of swarthy pimples, dried goats' milk cheese, steeped in honey and vinegar, is applied in the bath, no oil being used. Pustules are treated with ashes of swine's dung, applied with water, or else ashes of deer's antlers.

Detailed table of contents

CHAP. 70.

REMEDIES FOR SPRAINS, INDURATIONS, AND BOILS.

For the cure of sprains the following applications are used; wild boars' dung or swine's dung; calves' dung; wild boars' foam, used fresh with vinegar; goats' dung, applied with honey; and raw beef, used as a plaster. For swellings, swine's dung is used, warmed in an earthen pot, and beaten up with oil. The best emollient for all kinds of indurations upon the body is wolf's fat, applied topically. In the case of sores which are wanted to break, the most effectual plan is to apply cow-dung warmed in hot ashes, or else goats' dung boiled in vinegar or wine. For the cure of boils, beef-suet is applied with salt; but if they are attended with pain, it is melted with oil, and no salt is used. Goat-suet is employed in a similar manner.

Detailed table of contents

CHAP. 71.

REMEDIES FOR BURNS. THE METHOD OF TESTING BULL-GLUE; SEVEN REMEDIES DERIVED FROM IT.

For the treatment of burns, bears' grease is used, with lily roots; dried wild boars' dung also, or swine's dung; the ashes of burnt bristles, extracted from plasterers' brushes, beaten up with grease; the pastern-bone of an ox, reduced to ashes, and mixed with wax and bull's marrow or deer's marrow; or the dung of a hare. The dung, too, of a she-goat, they say, will effect a cure without leaving any scars.

The best glue is that prepared from the ears and genitals of the bull, and there is no better cure in existence for burns. There is nothing, however, that is more extensively adulterated; which is done by boiling up all kinds of old skins, and shoes even, for the purpose. The Rhodian glue is the purest of all, and it is this that painters and physicians mostly use. The whiter it is, the more highly glue is esteemed: that, on the other hand, which is black and brittle like wood, is looked upon is good for nothing.

[Detailed table of contents](#)

CHAP. 72.

REMEDIES FOR AFFECTIONS OF THE SINEWS AND FOR CONTUSIONS.

For pains in the sinews, goats' dung, boiled in vinegar with honey, is considered one of the most useful remedies, and this even where the sinew is threatened with putrefaction. Strains and contusions are healed with wild boars' dung, that has been gathered in spring and dried. A similar method is employed where persons have been dragged by a chariot or lacerated by the wheels, or have received contusions in any other way, the application being quite as effectual, should the dung happen to be fresh. Some think it a better plan, however, to boil it in vinegar; and if only powdered and taken in vinegar, they vouch for its good effects where persons are ruptured, wounded internally, or suffering from the effects of a fall.

Others again, who are of a more scrupulous tendency, take the ashes of it in water; and the Emperor Nero, it is said, was in the habit of refreshing himself with this drink, when he attempted to gain the public applause at the three-horse chariot races. Swine's dung, it is generally thought, is the next best to that of the goat.

Detailed table of contents

CHAP. 73. (18.)

REMEDIES FOR HÆMORRHAGE.

Hæmorrhage is arrested by applying deer's rennet with vinegar, hare's rennet, hare's fur reduced to ashes, or ashes of burnt asses' dung. The dung, however, of male animals is the most efficacious for this purpose, being mixed with vinegar, and applied with wool, in all cases of hæmorrhage. In the same way, too, the ashes of a horse's head or thigh, or of burnt calves' dung, are used with vinegar; the ashes also of a goat's horns or dung, with vinegar. But it is the thick blood that issues from the liver of a he-goat when cut asunder, that is looked upon as the most efficacious; or else the ashes of the burnt liver of a goat of either sex, taken in wine or applied to the nostrils with vinegar. The ashes, too, of a leather wine-bottle — but only when made of he-goat skin — are used very efficiently with an equal quantity of resin, for the purpose of stanching blood, and knitting together the lips of the wound. A kid's rennet in vinegar, or the thighs of that animal, reduced to ashes, are said to be productive of a similar result.

[Detailed table of contents](#)

CHAP. 74.

REMEDIES FOR ULCERS AND CARACINOMATOUS SORES.

Ulcers upon the legs and thighs are cured by an application of bears' grease, mixed with red earth: and those of a serpiginous nature by using wild boar's gall, with resin and white lead; the jaw-bone of a wild boar or swine, reduced to ashes; swine's dung in a dry state; or goats' dung, made luke-warm in vinegar. For otter kinds of ulcers butter is used, as a detergent, and as tending to make new flesh; ashes of deer's antlers, or deer's marrow; or else bull's gall, mixed with oil of cyprus or oil of iris. Wounds inflicted with edged weapons are rubbed with fresh swine's dung, or with dried swine's dung, powdered. When ulcers are phagedænic or fistulous, bull's gall is injected, with leek-juice or woman's milk; or else bull's blood, dried and powdered, with the plant cotyledon.

Carcinomatous sores are treated with hare's rennet, sprinkled upon them with an equal proportion of capers in wine; gangrenes, with bears' grease, applied with a feather; and ulcers of a serpiginous nature with the ashes of an ass's hoofs, powdered upon them. The blood of the horse corrodes the flesh by virtue of certain septic powers which it possesses; dried horse-dung, too, reduced to ashes, has a similar effect. Those kinds of ulcer which are commonly known as "phagedænic," are treated with the ashes of a cow's hide, mixed with honey. Calves' flesh, as also cow-dung mixed with honey, prevents recent wounds from swelling. The ashes of a leg of veal, applied with woman's milk, are a cure for sordid ulcers, and the malignant sore known as "cacoëthes;" bull-glue, melted, is applied to recent wounds inflicted with edged weapons, the application being removed before the end of three days. Dried goats' milk cheese, applied with vinegar and honey, acts as a detergent upon ulcers; and goat suet, used in combination with wax, arrests the spread of serpiginous sores if employed with pitch and sulphur, it will effect a thorough cure. The ashes of a kid's leg, applied with woman's milk, have a similar effect upon malignant ulcers; for the cure, too, of carbuncles, a sow's brains are roasted and applied.

Detailed table of contents

CHAP. 75.

REMEDIES FOR THE ITCH.

The itch in man is cured very effectually by using the marrow of an ass, or the urine of that animal, applied with the mud it has formed upon the ground. Butter, too, is very good; as also in the case of beasts of burden, if applied with warmed resin: bull glue is also used, melted in vinegar, and incorporated with lime; or goat's gall, mixed with calcined alum. The eruption called "boa," is treated with cow-dung, a fact to which it is indebted for its name. The itch in dogs is cured by an application of fresh cows' blood, which, when quite dry, is renewed a second time, and is rubbed off the next day with strong lie-ashes.

Detailed table of contents

CHAP. 76.

METHODS OF EXTRACTING FOREIGN SUBSTANCES WHICH ADHERE TO THE, BODY, AND OF RESTORING SCARS TO THEIR NATURAL COLOUR.

Thorns and similar foreign substances are extracted from the body by using cats' dung, or that of she-goats, with wine; the rennet also of any kind of animal, that of the hare more particularly, with powdered frankincense and oil, or an equal quantity of mistletoe, or else with bee-glue.

Ass suet restores scars of a swarthy hue to their natural colour; and they are equally effaced by using calf's gall made warm. Medical men add myrrh, honey, and saffron, and keep the mixture in a copper box; some, too, incorporate with it flower of copper.

[Detailed table of contents](#)

CHAP. 77. (19.)

REMEDIES FOR FEMALE DISEASES.

Menstruation is promoted by using hall's gall, in unwashed wool, as a pessary: Olympias of Thebe adds hyssop and nitre. Ashes, too, of deer's horns are taken in drink for the same purpose, and for derangements of the uterus they are applied topically, as also bull's gall, used as a pessary with opium, in the proportion of two oboli. It is a good plan, too, to use fumigations for the uterus, made with deer's hair, burnt. Hinds, they say, when they find themselves pregnant, are in the habit of swallowing a small stone. This stone, when found in their excrements, or in the uterus — for it is to be found there as well — attached to the body as an amulet, is a preventive of abortion. There are also certain small stones, found in the heart and uterus of these animals, which are very useful for women during pregnancy and in travail. As to the kind of pumice-stone which is similarly found in the uterus of the cow, we have already mentioned it when treating of the formation of that animal.

A wolf's fat, applied externally, acts emolliently upon the uterus, and the liver of a wolf is very soothing for pains in that organ. It is found advantageous for women, when near delivery, to eat wolf's flesh, or, if they are in travail, to have a person near them who has eaten it; so much so, indeed, that it will act as a countercharm even to any noxious spells which may have been laid upon them. In case, however, a person who has eaten wolf's flesh should happen to enter the room at the moment of parturition, dangerous effects will be sure to follow. The hare, too, is remarkably useful for the complaints of females: the lights of that animal, dried and taken in drink, are beneficial to the uterus; the liver, taken in water with Samian earth, acts as an emmenagogue; and the rennet brings away the after-birth, due care being taken by the patient not to bathe the day before. Applied in wool as a pessary, with saffron and leek-juice, this last acts as an expellent upon the dead fœtus. It is a general opinion that the uterus of a hare, taken with the food, promotes the conception of male offspring, and that a similar effect is produced by using the testes and rennet of that animal. It is thought, too, that a leveret, taken from the uterus of its dam, is a restorative of fruitfulness to women who are otherwise past child-bearing. But it is the blood of a hare's fœtus that the magicians recommend males to drink: while for young girls they prescribe nine pellets of hare's dung, to ensure a durable firmness to the breasts. For a similar purpose, also, they apply hare's rennet with honey; and to prevent hairs from growing again when once removed, they use a liniment of hare's blood.

For inflations of the uterus, it is found a good plan to apply wild boars' dung or swine's dung topically with oil: but a still more effectual remedy is to dry the dung, and sprinkle it, powdered, in the patient's drink, even though

she should be in a state of pregnancy or suffering the pains of child-birth. By administering sow's milk with honied wine, parturition is facilitated; and if taken by itself it will promote the secretion of the milk when deficient in nursing women. By rubbing the breasts of females with sow's blood they are prevented from becoming too large. If pains are felt in the breasts, they will be alleviated by drinking asses' milk; and the same milk, taken with honey, has considerable efficacy as an emmenagogue. Stale fat, too, from the same animal, heals ulcerations of the uterus: applied as a pessary, in wool, it acts emolliently upon indurations of that organ; and, applied fresh by itself, or in water when stale, it has all the virtues of a depilatory.

An ass's milt, dried and applied in water to the breasts, promotes the secretion of the milk; and used in the form of a fumigation, it acts as a corrective upon the uterus. A fumigation made with a burnt ass's hoof; placed beneath a woman, accelerates parturition, so much so, indeed, as to expel the dead foetus even: hence it is that it should only be employed in cases of miscarriage, it having a fatal effect upon the living foetus. Asses' dung, applied fresh, has a wonderful effect, they say, in arresting discharges of blood in females: the same, too, with the ashes of this dung, which, used as a pessary, are very good for the uterus. If the skin is rubbed with the foam from a horse's mouth for forty days together, before the first hair has made its appearance, it will effectually prevent the growth thereof: a decoction, too, made from deer's antlers is productive of a similar effect, being all the better if they are used quite fresh. Mares' milk, used as an injection, is highly beneficial to the uterus.

Where the foetus is felt to be dead in the uterus, the lichens or excrescences from a horse's legs, taken in fresh water, will act as an expellent: an effect produced also by a fumigation made with the hoofs or dry dung of that animal. Procidence of the uterus is arrested by using butter, in the form of an injection; and indurations of that organ are removed by similarly employing ox-gall, with oil of roses, turpentine being applied externally in wool. They say, too, that a fumigation, made from ox-dung, acts as a corrective upon procidence of the uterus, and facilitates parturition; and that conception is promoted by the use of cows' milk. It is a well-known fact that sterility is often entailed by suffering in child-birth; an evil which may be averted, Olympias of Thebes assures us, by rubbing the parts, before sexual intercourse, with bull's gall, serpents' fat, verdigrease, and honey. In cases, too, where menstruation is too abundant, the external parts should be sprinkled with a solution of calf's gall, the moment before the sexual congress; a method which acts emolliently also upon indurations of the abdomen. Applied to the navel as a liniment, it arrests excessive discharges, and is generally beneficial to the uterus. The proportions generally adopted are — one denarius of gall, one-third of a denarius of opium, and as much oil of almonds as may appear to be requisite; the whole being applied in sheep's wool. The gall, too, of a bull-calf is beaten up with half the quantity of honey,

and kept in readiness for the treatment of uterine diseases. If a woman about the time of conception eats roasted veal with the plant aristolochia, she will bring forth a male child, we are assured. Calf's marrow, boiled in wine and water with the suet, and applied as a pessary, is good for ulcerations of the uterus; the same, too, with foxes' fat and cats' dung, the last being applied with resin and oil of roses.

It is considered a remarkably good plan to subject the uterus to fumigations made with burnt goats' horns. The blood of the wild goat, mixed with sea-palm, acts as a depilatory. The gall of the other kinds of goat, used as an injection, acts emolliently upon callosities of the uterus, and ensures conception immediately after menstruation: it possesses also the virtues of a depilatory, the application being left for three days upon the flesh after the hair has been removed. The midwives assure us that she-goats' urine, taken in drink, and the dung, applied topically, will arrest uterine discharges, however much in excess. The membrane in which the kid is enclosed in the uterus, dried and taken in wine, acts as an expellent upon the after-birth. For affections of the uterus, it is thought a desirable plan to fumigate it with burnt kids' hair; and for discharges of blood, kids' rennet is administered in drink, or seed of henbane is applied. According to Osthane, if a woman's loins are rubbed with blood taken from the ticks upon a black wild bull, she will be inspired with an aversion to sexual intercourse: she will forget, too, her former love, by taking a he-goat's urine in drink, some nard being mixed with it to disguise the loathsome taste.

CHAP. 78.

REMEDIES FOR THE DISEASES OF INFANTS.

For infants there is nothing more useful than butter, either by itself or in combination with honey; for dentition more particularly, for soreness of the gums, and for ulcerations of the mouth. A wolf's tooth, attached to the body, prevents infants from being startled, and acts as a preservative against the maladies attendant upon dentition; an effect equally produced by making use of a wolf's skin. The larger teeth, also, of a wolf, attached to a horse's neck, will render him proof against all weariness, it is said. A hare's rennet, applied to the breasts of the nurse, effectually prevents diarrhœa in the infant suckled by her. An ass's liver, mixed with a little panax, and dropped into the mouth of an infant, will preserve it from epilepsy and other diseases to which infants are liable; this, however, must be done for forty days, they say. An ass's skin, too, thrown over infants, renders them insensible to fear. The first teeth shed by a horse, attached as an amulet to infants, facilitate dentition, and are better still, when not allowed to touch the ground. For pains in the spleen, an ox's milt is administered in honey, and applied topically; and for running ulcers it is used as an application, with honey. A calf's milt, boiled in wine, is beaten up, and applied to incipient ulcers of the mouth.

The magicians take the brains of a she-goat, and, after passing them through a gold ring, drop them into the mouth of the infant before it takes the breast, as a preservative against epilepsy and other infantile diseases. Goats' dung, attached to infants in a piece of cloth, prevents them from being restless, female infants in particular. By rubbing the gums of infants with goats' milk or hare's brains, dentition is greatly facilitated.

CHAP. 79.

PROVOCATIVES OF SLEEP.

Cato was of opinion that hare's flesh, taken as a diet, is provocative of sleep. It is a vulgar notion, too, that this diet confers beauty for nine days on those who use it; a silly play upon words, no doubt, but a notion which has gained far too extensively not to have had some real foundation. According to the magicians, the gall of a she-goat, but only of one that has been sacrificed, applied to the eyes or placed beneath the pillow, has a narcotic effect. Too profuse perspiration is checked by rubbing the body with ashes of burnt goats' horns mixed with oil of myrtle.

CHAP. 80.

STIMULANTS FOR THE SEXUAL PASSIONS.

Among the aphrodisiacs, we find mentioned, a wild boar's gall, applied externally; swine's marrow, taken inwardly; asses' fat, mixed with the grease of a gander and applied as a liniment; the virulent substance described by Virgil as distilling from mares when covered; and the dried testes of a horse, pulverized and mixed with the drink. The right testicle, also, of an ass, is taken in a proportionate quantity of wine, or worn attached to the arm in a bracelet; or else the froth discharged by that animal after covering, collected in a piece of red cloth and enclosed in silver, as Osthane informs us. Salpe recommends the genitals of this animal to be plunged seven times in boiling oil, and the corresponding parts to be well rubbed therewith. Balcon says that these genitals should be reduced to ashes and taken in drink; or else the urine: that has been voided by a bull immediately after covering: lie recommends, also, that the groin should be well rubbed with earth moistened with this urine.

Mouse-dung, on the other hand, applied in the form of a liniment, acts as an antaphrodisiac. The lights of a wild boar or swine, roasted, are an effectual preservative against drunkenness; they must, however, be eaten fasting, and upon the same day. The lights of a kid, too, are productive of the same effect.

CHAP. 81. (20.)

REMARKABLE FACTS RELATIVE TO ANIMALS.

In addition to those already mentioned, there are various other marvellous facts related, with reference to these animals. When a horse-shoe becomes detached from the hoof, as often is the case, if a person takes it up and puts it by, it will act as a remedy for hiccup the moment he calls to mind the spot where he has placed it. A wolf's liver, they say, is similar to a horse's hoof in appearance; and a horse, they tell us, if it follows in the track of a wolf, will burst asunder beneath its rider. The pastern-bones of swine have a certain tendency to promote discord, it is said. In cases of fire, if some of the dung can be brought away from the stalls, both sheep and oxen may be got out all the more easily, and will make no attempt to return. The flesh of a he-goat will lose its rank smell, if the animal has eaten barley-bread, or drunk an infusion of laser the day on which it was killed. Meat that has been salted while the moon was on the wane, will never be attacked by worms. In fact, so great has been the care taken to omit no possible researches, that a deaf hare, we find, will grow fat sooner than one that can hear!

As to the remedies for the diseases of animals — If a beast of burden voids blood, an injection must be used of swine's dung mixed with wine. For the maladies of oxen, a mixture of suet is used with quicksilver, and wild garlic boiled; the whole eaten up and administered in wine. The fat, too, of a fox is employed. The liquor of boiled horse-flesh, administered in their drink, is recommended for the cure of diseased swine: and, indeed, the maladies of all four-footed beasts may be effectually treated by boiling a she-goat whole, in her skin, along with a bramble-frog. Poultry, they say, will never be touched by a fox, if they have eaten the dried liver of that animal, or if the cock, when treading the hen, has had a piece of fox's skin about his neck. The same property, too, is attributed to a weazel's gall. The oxen in the Isle of Cyprus cure themselves of gripings in the abdomen, it is said, by swallowing human excrements: the feet, too, of oxen will never be worn to the quick, if their hoofs are well rubbed with tar before they begin work. Wolves will never approach a field, if, after one has been caught and its legs broken and throat cut, the blood is dropped little by little along the boundaries of the field, and the body buried on the spot from which it was first dragged. The share, too, with which the first furrow in the field has been traced in the current year, should be taken from the plough, and placed upon the hearth of the Lares, where the family is in the habit of meeting, and left there till it is consumed: so long as this is in doing, no wolf will attack any animal in the field.

We will now turn to an examination of those animals which, being neither tame nor wild, are of a nature peculiar to themselves.

SUMMARY. — Remedies, narratives, and observations, one thousand six

hundred and eighty-two.

ROMAN AUTHORS QUOTED. — M. Varro, L. Piso, Fabianus, Valerius Antias, Verrius Flaccus, Cato the Censor, Servius Sulpicius, Licinius Macer, Celsus, Massurius, Sextius Niger who wrote in Greek, Bithus of Dyrrhachium, Opilius the physician, Granius the physician.

FOREIGN AUTHORS QUOTED. — Democritus, Apollonius who wrote the “Myrosis,” Melitus, Artemon, Sextilius, Autæus, Homer, Theophrastus, Lysimachus, Attalus, Xenocrates, Orpheus who wrote the “Idiophya,” Archelaüs who wrote a similar work, Demetrius, Sotira, Laïs, Elephantis, Salpe, Olympias of Thebes, Diotimus of Thebes, Iollas, Andreas, Marcion of Smyrna, Æschines the physician, Hippocrates, Aristotle, Metrodorus of Scepsos, Icetidas the physician, Apelles the physician, Hesiod, Dalion, Cæcilius, Bion who wrote “On Powers,” Anaxilais, King Juba.

CHAP. 1. (1.)

THE ORIGIN OF THE MEDICAL ART.

THE nature and multiplicity of the various remedies already described or which still remain to be enlarged upon, compel me to enter upon some further details with reference to the art of medicine itself: aware as I am, that no one has hitherto treated of this subject in the Latin tongue, and that if all new enterprises are difficult or of doubtful success, it must be one in particular which is so barren of all charms to recommend it, and accompanied with such difficulties of illustration. It will not improbably suggest itself, however, to those who are familiar with this subject, to make enquiry how it is that in the practice of medicine the use of simples has been abandoned, so convenient as they are and so ready prepared to our hand: and they will be inclined to feel equal surprise and indignation when they are informed that no known art, lucrative as this is beyond all the rest, has been more fluctuating, or subjected to more frequent variations.

Commencing by ranking its inventors in the number of the gods, and consecrating for them a place in heaven, the art of medicine, at the present day even, teaches us in numerous instances to have recourse to the oracles for aid. In more recent times again, the same art has augmented its celebrity, at the cost perhaps of being charged with criminality, by devising the fable that Æsculapius was struck by lightning for presuming to raise Tyndareus to life. And this example notwithstanding, it has not hesitated to relate how that others, through its agency, have since been restored to life. Already enjoying celebrity in the days of the Trojan War, its traditions from that period have acquired an additional degree of certainty; although in those times, we may remark, the healing art confined itself solely to the treatment of wounds.

CHAP. 2.

PARTICULARS RELATIVE TO HIPPOCRATES. DATE OF THE ORIGIN OF CLINICAL PRACTICE AND OF THAT OF IATRALIPTICS.

Its succeeding history, a fact that is truly marvellous, remains enveloped in the densest night, down to the time of the Peloponnesian War; at which period it was restored to light by the agency of Hippocrates, a native of Cos, an island flourishing and powerful in the highest degree, and consecrated to Æsculapius. It being the practice for persons who had recovered from a disease to describe in the temple of that god the remedies to which they had owed their restoration to health, that others might derive benefit therefrom in a similar emergency; Hippocrates, it is said, copied out these prescriptions, and, as our fellow-countryman Varro will have it, after burning the temple to the ground, instituted that branch of medical practice which is known as "Clinics." There was no limit after this to the profits derived from the practice of medicine; for Prodicus, a native of Selymbria, one of his disciples, founded the branch of it known as "Iatraliptics," and so discovered a means of enriching the very anointers even and the commonest drudges employed by the physicians.

CHAP. 3.

PARTICULARS RELATIVE TO CHRYSIPPUS AND ERASISTRATUS.

In the rules laid down by these professors, changes were effected by Chrysippus with a vast parade of words, and, after Chrysippus, by Erasistratus, son of the daughter of Aristotle. For the cure of King Antiochus—to give our first illustration of the profits realized by the medical art—Erasistratus received from his son, King Ptolemæus, the sum of one hundred talents.

CHAP. 4.

THE EMPIRIC BRANCH OF MEDICINE.

Another sect again, known as that of the Empirics — because it based its rules upon the results of experiment — took its rise in Sicily, having for its founder Acron of Agrigentum, a man recommended by the high authority of Empedocles the physician.

CHAP. 5.

PARTICULARS RELATIVE TO HEROPHILUS AND OTHER CELEBRATED PHYSICIANS. THE VARIOUS CHANGES THAT HAVE BEEN MADE IN THE SYSTEM OF MEDICINE.

These several schools of medicine, long at variance among themselves, were all of them condemned by Herophilus, who regulated the arterial pulsation according to the musical scale, correspondingly with the age of the patient. In succeeding years again, the theories of this sect were abandoned, it being found that to belong to it necessitated an acquaintance with literature. Changes, too, were effected in the school, of which, as already stated, Asclepiades had become the founder. His disciple, Themison, who at first in his writings implicitly followed him, soon afterwards, in compliance with the growing degeneracy of the age, went so far as to modify his own methods of treatment; which, in their turn, were entirely displaced, with the authorization of the late Emperor Augustus, by Antonius Musa, a physician who had rescued that prince from a most dangerous malady, by following a mode of treatment diametrically opposite. I pass over in silence many physicians of the very highest celebrity, the Cassii, for instance, the Calpetani, the Arruntii, and the Rubrii, men who received fees yearly from the great, amounting to no less than two hundred and fifty thousand sesterces. As for Q. Stertinius, he thought that he conferred an obligation upon the emperors in being content with five hundred thousand sesterces per annum; and indeed he proved, by an enumeration of the several houses, that a city practice would bring him in a yearly income of not less than six hundred thousand sesterces.

Fully equal to this was the sum lavished upon his brother by Claudius Cæsar; and the two brothers, although they had drawn largely upon their fortunes in beautifying the public buildings at Neapolis, left to their heirs no less than thirty millions of sesterces! such an estate as no physician but Arruntius had till then possessed.

Next in succession arose Vettius Valens, rendered so notorious by his adulterous connection with Messalina, the wife of Claudius Cæsar, and equally celebrated as a professor of eloquence. When established in public favour, he became the founder of a new sect.

It was in the same age, too, during the reign of the Emperor Nero, that the destinies of the medical art passed into the hands of Thessalus, a man who swept away all the precepts of his predecessors, and declaimed with a sort of frenzy against the physicians of every age; but with what discretion and in what spirit, we may abundantly conclude from a single trait presented by his character — upon his tomb, which is still to be seen on the Appian Way, he had his name inscribed as the “Iatronices” — the “Conqueror of the Physicians.” No stage-player, no driver of a three-horse chariot, had a greater throng attending him when he appeared in public: but he was at last eclipsed

in credit by Crinas, a native of Massilia, who, to wear an appearance of greater discreetness and more devoutness, united in himself the pursuit of two sciences, and prescribed diets to his patients in accordance with the movements of the heavenly bodies, as indicated by the almanacks of the mathematicians, taking observations himself of the various times and seasons. It was but recently that he died, leaving ten millions of sesterces, after having expended hardly a less sum upon building the walls of his native place and of other towns.

It was while these men were ruling our destinies, that all at once, Charmis, a native also of Massilia, took the City by surprise. Not content with condemning the practice or preceding physicians, he proscribed the use of warm baths as well, and persuaded people, in the very depth of winter even, to immerse themselves in cold water. His patients he used to plunge into large vessels filled with cold water, and it was a common thing to see aged men of consular rank make it a matter of parade to freeze themselves; a method of treatment, in favour of which Annæus Seneca gives his personal testimony, in writings still extant.

There can be no doubt whatever, that all these men, in the pursuit of celebrity by the introduction of some novelty or other, made purchase of it at the downright expense of human life. Hence those woeful discussions, those consultations at the bedside of the patient, where no one thinks fit to be of the same opinion as another, lest he may have the appearance of being subordinate to another; hence, too, that ominous inscription to be read upon a tomb, "It was the multitude of physicians that killed me."

The medical art, so often modified and renewed as it has been, is still on the change from day to day, and still are we impelled onwards by the puffs which emanate from the ingenuity of the Greeks. It is quite evident too, that every one among them that finds himself skilled in the art of speech, may forthwith create himself the arbiter of our life and death: as though, forsooth, there were not thousands of nations who live without any physicians at all, though not, for all that, without the aid of medicine. Such, for instance, was the Roman people, for a period of more than six hundred years; a people, too, which has never shown itself slow to adopt all useful arts, and which even welcomed the medical art with avidity, until, after a fair experience of it, there was found good reason to condemn it.

[Detailed table of contents](#)

CHAP. 6.

WHO FIRST PRACTISED AS A PHYSICIAN AT ROME, AND AT WHAT PERIOD.

And, indeed, it appears to me not amiss to take the present opportunity of reviewing some remarkable facts in the days of our forefathers connected with this subject. Cassius Hemina, one of our most ancient writers, says that the first physician that visited Rome was Archagathus, the son of Lysanias, who came over from Peloponnesus, in the year of the City 535, L. Æmilius and M. Livius being consuls. He states also, that the right of free citizenship was granted him, and that he had a shop provided for his practice at the public expense in the Acilian Cross-way; that from his practice he received the name of “Vulnerarius;” that on his arrival he was greatly welcomed at first, but that soon afterwards, from the cruelty displayed by him in cutting and searing his patients, he acquired the new name of “Carnifex,” and brought his art and physicians in general into considerable disrepute.

That such was the fact, we may readily understand from the words of M. Cato, a man whose authority stands so high of itself, that but little weight is added to it by the triumph which he gained, and the Censorship which he held. I shall, therefore, give his own words in reference to this subject.

CHAP. 7.

THE OPINIONS ENTERTAINED BY THE ROMANS ON THE ANCIENT PHYSICIANS.

“Concerning those Greeks, son Marcus, I will speak to you more at length on the befitting occasion. I will show you the results of my own experience at Athens, and that, while it is a good plan to dip into their literature, it is not worth while to make a thorough acquaintance with it. They are a most iniquitous and intractable race, and you may take my word as the word of a prophet, when I tell you, that whenever that nation shall bestow its literature upon Rome it will mar everything; and that all the sooner, if it sends its physicians among us. They have conspired among themselves to murder all barbarians with their medicine; a profession which they exercise for lucre, in order that they may win our confidence, and dispatch us all the more easily. They are in the common habit, too, of calling us barbarians, and stigmatize us beyond all other nations, by giving us the abominable appellation of Opici. I forbid you to have anything to do with physicians.”

Detailed table of contents

CHAP. 8.

EVILS ATTENDANT UPON THE PRACTICE OF MEDICINE.

Cato, who wrote to this effect, died in his eighty-fifth year, in the year of the City 605; so that no one is to suppose that he had not sufficient time to form his experience, either with reference to the duration of the republic, or the length of his own life. Well then-are we to conclude that he has stamped with condemnation a thing that in itself is most useful? Far from it, by Hercules! for he subjoins an account of the medical prescriptions, by the aid of which he had ensured to himself and to his wife a ripe old age; prescriptions upon which we are now about to enlarge. He asserts also that he has a book of recipes in his possession, by the aid of which he treats the maladies of his son, his servants, and his friends; a book from which we have extracted the various prescriptions according to the several maladies for which they are employed.

It was not the thing itself that the ancients condemned, but it was the art as then practised, and they were shocked, more particularly, that man should pay so dear for the enjoyment of life. For this reason it was, they say, that the Temple of Æsculapius, even after he was received as a divinity, was built without the City, and afterwards on an island; for this reason, too, it was, that when, long after the time of Cato, the Greeks were expelled from Italy, the physicians were not exempted from the decree. And here I will improve upon the foresight displayed by them. Medicine is the only one of the arts of Greece, that, lucrative as it is, the Roman gravity has hitherto refused to cultivate. It is but very few of our fellow-citizens that have even attempted it, and so soon as ever they have done so, they have become deserters to the Greeks forth with. Nay, even more than this, if they attempt to treat of it in any other language than Greek, they are sure to lose all credit, with the most ignorant even, and those who do not understand a word of Greek; there being all the less confidence felt by our people in that which so nearly concerns their welfare, if it happens to be intelligible to them. In fact, this is the only one of all the arts, by Hercules! in which the moment a man declares himself to be an adept, he is at once believed, there being at the same time no imposture, the results of which are more fraught with peril. To all this, however, we give no attention, so seductive is the sweet influence of the hope entertained of his ultimate recovery by each.

And then besides, there is no law in existence whereby to punish the ignorance of physicians, no instance before us of capital punishment inflicted. It is at the expense of our perils that they learn, and they experimentalize by putting us to death, a physician being the only person that can kill another with sovereign impunity. Nay, even more than this, all the blame is thrown upon the sick man only; he is accused of disobedience forthwith, and it is the person who is dead and gone that is put upon his trial. It is the usage at Rome

for the decuries to pass examination under the censorship of the emperor, and for inquisitions to be made at our party-walls even: persons who are to sit in judgment on our monetary matters are sent for to Gades and the very Pillars of Hercules; while a question of exile is never entertained without a panel of forty-five men selected for the purpose. But when it is the judge's own life that is at stake, who are the persons that are to hold council upon it, but those who the very next moment are about to take it!

And yet so it is, that we only meet with our deserts, no one of us feeling the least anxiety to know what is necessary for his own welfare. We walk with the feet of other people, we see with the eyes of other people, trusting to the memory of others we salute one another, and it is by the aid of others that we live. The most precious objects of existence, and the chief supports of life, are entirely lost to us, and we have nothing left but our pleasures to call our own. I will not leave Cato exposed to the hatred of a profession so ambitious as this, nor yet that senate which judged as he did, but at the same time I will pursue my object without wresting to my purpose the crimes practised by its adepts, as some might naturally expect. For what profession has there been more fruitful in poisonings, or from which there have emanated more frauds upon wills And then, too, what adulteries have been committed, in the very houses of our princes even! the intrigue of Eudemus, for example, with Livia, the wife of Drusus Cæsar, and that of Valens with the royal lady previously mentioned. Let us not impute these evils, I say, to the art, but to the men who practise it; for Cato, I verily believe, as little apprehended such practices as these in the City, as he did the presence of royal ladies there.

I will not accuse the medical art of the avarice even of its professors, the rapacious bargains made with their patients while their fate is trembling in the balance, the tariffs framed upon their agonies, the monies taken as earnest for the dispatching of patients, or the mysterious secrets of the craft. I will not mention how that cataract must be couched only, in the eye, in preference to extracting it at once — practices, all of them, which have resulted in one very great advantage, by alluring hither such a multitude of adventurers; it being no moderation on their part, but the rivalry existing between such numbers of practitioners, that keeps their charges within moderation. It is a well-known fact that Charmis, the physician already mentioned, made a bargain with a patient of his in the provinces, that he should have two hundred thousand sesterces for the cure; that the Emperor Claudius extorted from Alcon, the surgeon, ten millions of sesterces by way of fine; and that the same man, after being recalled from his exile in Gaul, acquired a sum equally large in the course of a few years.

These are faults, however, which must be imputed to individuals only; and it is not my intention to waste reproof upon the dregs of the medical profession, or to call attention to the ignorance displayed by that crew, the violation of all regimen in their treatment of disease, the evasions practised in the use of warm baths, the strict diet they imperiously prescribe, the food that

is crammed into these same patients, exhausted as they are, several times a day; together with a thousand other methods of showing how quick they are to change their mind, their precepts for the regulation of the kitchen, and their recipes for the composition of unguents, it being one grand object with them to lose sight of none of the usual incitements to sensuality. The importation of foreign merchandize, and the introduction of tariffs settled by foreigners, would have been highly displeasing to our ancestors, I can readily imagine; but it was not these inconveniences that Cato had in view, when he spoke thus strongly in condemnation of the medical art.

“Theriace” is the name given to a preparation devised by luxury; a composition formed of six hundred different ingredients; and this while Nature has bestowed upon us such numbers of remedies, each of which would have fully answered the purpose employed by itself! The Mithridatic antidote is composed of four and fifty ingredients, none of which are used in exactly the same proportion, and the quantity prescribed is in some cases so small as the sixtieth part of one denarius! Which of the gods, pray, can have instructed man in such trickery as this, a height to which the mere subtlety of human invention could surely never have reached? It clearly must emanate from a vain ostentation of scientific skill, and must be set down as a monstrous system of puffing off the medical art.

And yet, after all, the physicians themselves do not understand this branch of their profession; and I have ascertained that it is a common thing for them to put mineral vermilion in their medicines, a rank poison, as I shall have occasion to show when I come to speak of the pigments, in place of Indian cinnabar, and all because they mistake the name of the one drug for that of the other! These, however, are errors which only concern the health of individuals, while it is the practices which Cato foresaw and dreaded, less dangerous in themselves and little regarded, practices, in fact, which the leading men in the art do not hesitate to avow, that have wrought the corruption of the manners of our empire.

The practices I allude to are those to which, while enjoying robust health, we submit: such, for instance, as rubbing the body with wax and oil, a preparation for a wrestling match, by rights, but which, these men pretend, was invented as a preservative of health; the use of hot baths, which are necessary, they have persuaded us, for the proper digestion of the food, baths which no one ever leaves without being all the weaker for it, and from which the more submissive of their patients are only carried to the tomb; potions taken fasting; vomits to clear the stomach, and then a series of fresh drenchings with drink; emasculation, self-inflicted by the use of pitch-plasters as depilatories; the public exposure, too, of even the most delicate parts of the female body for the prosecution of these practices. Most assuredly so it is, the contagion which has seized upon the public morals, has had no more fertile source than the medical art, and it continues, day by day even, to justify the claims of Cato to be considered a prophet and an oracle of wisdom, in that

assertion of his, that it is quite sufficient to dip into the records of Greek genius, without becoming thoroughly acquainted with them.

Such then is what may be said in justification of the senate and of the Roman people, during that period of six hundred years in which they manifested such repugnance to an art, by the most insidious terms of which, good men are made to lend their credit and authority to the very worst, and so strongly entered their protest against the silly persuasions entertained by those, who fancy that nothing can benefit them but what is coupled with high price.

I entertain no doubt, too, that there will be found some to express their disgust at the particulars which I am about to give, in relation to animals: and yet Virgil himself has not disdained — when, too, there was no necessity for his doing so—to speak of ants and weevils, “And nests by beetles made that shun the light.” Homer, too, amid his description of the battles of the gods, has not disdained to remark upon the voracity of the common fly; nor has Nature, she who engendered man, thought it beneath her to engender these insects as well. Let each then make it his care, not so much to regard the thing itself, as to rightly appreciate in each case the cause and its effects.

Detailed table of contents

CHAP. 9.

THIRTY-FIVE REMEDIES DERIVED FROM WOOL.

I shall begin then with some remedies that are well known, those namely, which are derived from wool and from the eggs of birds, thus giving due honour to those substances which hold the principal place in the estimation of mankind; though at the same time I shall be necessitated to speak of some others out of their proper place, according as occasion may offer. I should not have been at a loss for high-flown language with which to grace my narrative, had I made it my design to regard anything else than what, as being strictly trustworthy, becomes my work: for among the very first remedies mentioned, we find those said to be derived from the ashes and nest of the phoenix, as though, forsooth, its existence were a well ascertained fact, and not altogether a fable. And then besides, it would be a mere mockery to describe remedies that can only return to us once in a thousand years.

(2.) The ancient Romans attributed to wool a degree of religious importance even, and it was in this spirit that they enjoined that the bride should touch the door-posts of her husband's house with wool. In addition to dress and protection from the cold, wool, in an unwashed state, used in combination with oil, and wine or vinegar, supplies us with numerous remedies, according as we stand in need of an emollient or an excitant, an astringent or a laxative. Wetted from time to time with these liquids, greasy wool is applied to sprained limbs, and to sinews that are suffering from pain. In the case of sprains, some persons are in the habit of adding salt, while others, again, apply pounded rue and grease, in wool: the same, too, in the case of contusions or tumours. Wool will improve the breath, it is said, if the teeth and gums are rubbed with it, mixed with honey; it is very good, too, for phrenitis, used as a fumigation. To arrest bleeding at the nose, wool is introduced into the nostrils with oil of roses; or it is used in another manner, the ears being well plugged with it. In the case of inveterate ulcers it is applied topically with honey: soaked in wine or vinegar, or in cold water and oil, and then squeezed out, it is used for the cure of wounds.

Rams' wool, washed in cold water, and steeped in oil, is used for female complaints, and to allay inflammations of the uterus. Proclivity of the uterus is reduced by using this wool in the form of a fumigation. Greasy wool, used as a plaster and as a pessary, brings away the dead foetus, and arrests uterine discharges. Bites inflicted by a mad dog are plugged with unwashed wool, the application being removed at the end of seven days. Applied with cold water, it is a cure for agnails: steeped in a mixture of boiling nitre, sulphur, oil, vinegar, and tar, and applied twice a day, as warm as possible, it allays pains in the loins. By making ligatures with unwashed rams' wool about the extremities of the limbs, bleeding is effectually stopped.

In all cases, the wool most esteemed is that from the neck of the animal; the best kinds of wool being those of Galatia, Tarentum, Attica, and Miletus. For excoriations, blows, bruises, contusions, crushes, galls, falls, pains in the head and other parts, and for inflammation of the stomach, unwashed wool is applied, with a mixture of vinegar and oil of roses. Reduced to ashes, it is applied to contusions, wounds, and burns, and forms an ingredient in ophthalmic compositions. It is employed, also, for fistulas and suppurations of the ears. For this last purpose, some persons take the wool as it is shorn, while others pluck it from the fleece; they then cut off the ends of it, and after drying and carding it, lay it in pots of unbaked earth, steep it well in honey, and burn it. Others, again, arrange it in layers alternately with chips of torchpine, and, after sprinkling it with oil, set fire to it: they then rub the ashes into small vessels with the hands, and let them settle in water there. This operation is repeated and the water changed several times, until at last the ashes are found to be slightly astringent, without the slightest pungency; upon which, they are put by for use, being possessed of certain caustic properties, and extremely useful as a detergent for the eyelids.

Detailed table of contents

CHAP. 10.

THIRTY-TWO REMEDIES DERIVED FROM WOOL-GREASE.

And not only this, but the filthy excretions even of sheep, the sweat adhering to the wool of the flanks and of the axillary concavities — a substance known as “æsyphum” — are applied to purposes almost innumerable; the grease produced by the sheep of Attica being the most highly esteemed. There are numerous ways of obtaining it, but the most approved method is to take the wool, fresh clipped from those parts of the body, or else the sweat and grease collected from any part of the fleece, and boil it gently in a copper vessel upon a slow fire: this done, it is left to cool, and the fat which floats upon the surface collected into an earthen vessel. The material originally used is then subjected to another boiling, and the two results are washed in cold water; after which, they are strained through a linen cloth and exposed to the sun till they become bleached and quite transparent, and are then put by in a pewter box for keeping.

The best proof of its genuineness is its retention of the strong smell of the original grease, and its not melting when rubbed with water upon the hand, but turning white, like white-lead in appearance. This substance is extremely useful for inflammations of the eyes and indurations of the eyelids. Some persons bake the wool in an earthen pot, until it has lost all its grease, and are of opinion that, prepared this way, it is a more useful remedy for excoriations and indurations of the eyelids, for eruptions at the corners of the eyes, and for watery eyes. And not only does this grease heal ulcerations of the eyes, but, mixed with goose-grease, of the ears and generative organs as well; in combination also with melilote and butter, it is a cure for inflammations of the uterus, and for excoriations of the rectum and condylomata. The other uses to which it is applied, we shall detail on a more appropriate occasion.

The grease, too, of the wool about the tail is made up into pills, unmixed with any substance: these pills are dried and pulverized, being an excellent application for the teeth, when loose even, and for the gums, when attacked by spreading ulcers of a cancerous nature. Sheep’s wool, too, cleaned, is applied by itself, or with the addition of sulphur, for dull, heavy pains, and the ashes of it, burnt, are used for diseases of the generative organs: indeed, this wool is possessed of such sovereign virtues, that it is used as a covering for medicinal applications even. It is also an especial remedy for the sheep itself, when it has lost its stomach, and refuses to feed; for, upon plucking some wool from the tail, and then tying the tail therewith, as tight as possible, the sheep will fall to feeding immediately. It is said, however, that the part of the tail which lies beyond the knot so made will quickly mortify and die.

CHAP. 11. (3.)

TWENTY-TWO REMEDIES DERIVED FROM EGGS.

There is a considerable affinity also between wool and eggs, which are applied together as a frontal to the forehead by way of cure for defluxions of the eyes. Wool, however, is not required for this purpose to have been dressed with radicula, the only thing requisite to be combined with it being the white of an egg and powdered frankincense. The white of an egg, also applied by itself, arrests defluxions of the eyes, and has a cooling effect upon inflammations of those organs: some, however, prefer mixing saffron with it, and employ it as an ingredient in eye-salves, in place of water. For ophthalmia in infants there is hardly any remedy to be found, except white of egg mixed with fresh butter. Eggs beaten up with oil, are very soothing for erysipelas, beet leaves being laid on the liniment.

White of egg, mixed with pounded gum ammoniac, is used as a bandoline for arranging the hairs of the eyelids; and, in combination with pine-nuts and a little honey, it forms a liniment for the removal of pimples on the face. If the face is well rubbed with it, it will never be sun-burnt. If, the moment the flesh has been scalded, an egg is applied, no blisters will form: some persons, however, mix with it barley-meal and a little salt. In cases of ulceration formed by burns, there is nothing better than parched barley and hogs' lard, mixed with the white of an egg. The same mixture is also used as an application for diseases of the rectum, in infants even, and in cases, too, when there is procidence of those parts. For the cure of chaps upon the feet, white of eggs is boiled, with two denarii of white lead, an equal quantity of litharge, a little myrrh, and some wine. For the cure of erysipelas they use the whites of three eggs with amyllum: it is said, too, that white of egg has the effect of knitting wounds and of expelling urinary calculi. The yolk of eggs boiled hard, applied in woman's milk with a little saffron and honey, has a soothing effect upon pains in the eyes. The yolk is applied also to the eyes in wool, mixed with honied wine and oil of roses; or else mixed with ground parsley-seed and polenta, and applied with honied wine. The yolk of a single egg, swallowed raw by itself without being allowed to touch the teeth, is remarkably good for cough, defluxions of the chest, and irritations of the fauces. It is used, too, both internally and externally, in a raw state, as a sovereign cure for the sting of the hæmorrhoids; and it is highly beneficial for the kidneys, for irritations and ulcerations of the bladder, and for bloody expectorations. For dysentery, the yolks of five eggs are taken raw in one semi-sextarius of wine, mixed with the ashes of the shells, poppy-juice, and wine.

For cœliac fluxes, it is recommended to take the yolks of eggs, with like proportions of pulpy raisins and pomegranate rind, in equal quantities, for

three consecutive days; or else to follow another method, and take the yolks of three eggs, with three ounces of old bacon and honey, and three cyathi of old wine; the whole being beaten up to the consistency of honey, and taken in water, when needed, in pieces the size of a hazel nut. In some cases, too, the yolks of three eggs are fried in oil, the whole of the egg having been steeped a day previously in vinegar. It is in this way that eggs are used for the treatment of spleen diseases; but for spitting of blood, they should be taken with three cyathi of must. Yolk of egg is used, too, for the cure of bruises of long standing, in combination with bulbs and honey. Boiled and taken in wine, yolks of eggs arrest menstruation: applied raw with oil or wine, they dispel inflations of the uterus. Mixed with goose-grease and oil of roses, they are useful for crick in the neck; and they are hardened over the fire, and applied warm, for the cure of maladies of the rectum. For condylomata, eggs are used in combination with oil of roses; and for the treatment of burns, they are hardened in water, and set upon hot coals till the shells are burnt, the yellow being used as a liniment with oil of roses.

Eggs become entirely transformed into yolk, on being removed after the hen has sat upon them for three days; in which state they are known by the name of "sitista." The chicks that are found within the shell are used for strengthening a disordered stomach, being eaten with half a nut-gall, and no other food taken for the next two hours. They are given also for dysentery, boiled in the egg with one semisextarius of astringent wine, and an equal quantity of olive oil and polenta. The pellicle that lines the shell is used, either raw or boiled, for the cure of cracked lips; and the shell itself, reduced to ashes, is taken in wine for discharges of blood: care must be taken, however, to burn it without the pellicle. In the same way, too, a dentifrice is prepared. The ashes of the shell, applied topically with myrrh, arrest menstruation when in excess. So remarkably strong is the shell of an egg, that if it is set upright, no force or weight can break it, unless a slight inclination be made to one side or other of the circumference. Eggs taken whole in wine, with rue, dill, and cummin, facilitate parturition. Used with oil and cedar-resin, they remove itch and prurigo, and, applied in combination with cyclaminos, they are remedial for running ulcers of the head. For purulent expectorations and spitting of blood, a raw egg is taken, warmed with juice of cut-leek and an equal quantity of Greek honey. For coughs, eggs are administered, boiled and beaten up with honey, or else raw, with raisin wine and an equal quantity of olive oil. For diseases of the male organs, an injection is made, of an egg, three cyathi of raisin wine, and half an ounce of amyllum, the mixture being used immediately after the bath. Where injuries have been inflicted by serpents, boiled eggs are used as a liniment, beaten up with nasturtium.

In what various ways eggs are used as food is well known to all, passing downwards, however swollen the throat may be, and warming the parts as they pass. Eggs, too, are the only diet which, while it affords nutriment in sickness, does not load the stomach, possessing at the same moment all the

advantages both of food and drink. We have already stated, that the shell of an egg becomes soft when steeped in vinegar: it is by the aid of eggs thus prepared, and kneaded up with meal into bread, that patients suffering from the cœliac flux are often restored to strength. Some, however, think it a better plan to roast the eggs, when thus softened, in a shallow pan; a method, by the aid of which, they arrest not only looseness of the bowels, but excessive menstruation as well. In cases, again, where the discharges are greatly in excess, eggs are taken raw, with meal, in water. The yolks, too, are employed alone, boiled hard in vinegar and roasted with ground pepper, when wanted to arrest diarrhœa.

For dysentery, there is a sovereign remedy, prepared in the following manner: an egg is emptied into a new earthen vessel, which done, in order that all the proportions may be equal, fill the shell, first with honey, then with oil, and then with vinegar; beat them up together, and thoroughly incorporate them: the better the quality of the several ingredients, the more efficacious the mixture will be. Others, again, instead of oil and vinegar, use the same proportions of red resin and wine. There is also another way of making up this preparation: the proportion of oil, and of that only, remains the same, and to it they add two sixtieth parts of a denarius of the vegetable which we have spoken of under the name of “rhus,” and five oboli of honey. All these ingredients are boiled down together, and no food is eaten by the patient till the end of four hours after taking the mixture. Many persons, too, have a cure for griping pains in the bowels, by beating up two eggs with four cloves of garlick, and administering them, warmed in one semi-sextarius of wine.

Not to omit anything in commendation of eggs, I would here add that glair of egg, mixed with quicklime, unites broken glass. Indeed, so great is the efficacy of the substance of an egg, that wood dipped in it will not take fire, and cloth with which it has come in contact will not ignite. On this occasion, however, it is only of the eggs of poultry that I have been speaking, though those of the various other birds as well are possessed of many useful properties, as I shall have to mention on the appropriate occasions.

[Detailed table of contents](#)

CHAP. 12.

SERPENTS' EGGS.

In addition to the above, there is another kind of egg, held in high renown by the people of the Gallic provinces, but totally omitted by the Greek writers. In summer time, numberless snakes become artificially entwined together, and form rings around their bodies with the viscous slime which exudes from their mouths, and with the foam secreted by them: the name given to this substance is “anguinum.” The Druids tell us, that the serpents eject these eggs into the air by their hissing, and that a person must be ready to catch them in a cloak, so as not to let them touch the ground; they say also that he must instantly take to flight on horseback, as the serpents will be sure to pursue him, until some intervening river has placed a barrier between them. The test of its genuineness, they say, is its floating against the current of a stream, even though it be set in gold. But, as it is the way with magicians to be dexterous and cunning in casting a veil about their frauds, they pretend that these eggs can only be taken on a certain day of the moon; as though, forsooth, it depended entirely upon the human will to make the moon and the serpents accord as to the moment of this operation.

I myself, however, have seen one of these eggs: it was round, and about as large as an apple of moderate size; the shell of it was formed of a cartilaginous substance, and it was surrounded with numerous cupules, as it were, resembling those upon the arms of the polypus: it is held in high estimation among the Druids. The possession of it is marvellously vaunted as ensuring success in law-suits, and a favourable reception with princes; a notion which has been so far belied, that a Roman of equestrian rank, a native of the territory of the Vocontii, who, during a trial, had one of these eggs in his bosom, was slain by the late Emperor Tiberius, and for no other reason, that I know of, but because he was in possession of it. It is this entwining of serpents with one another, and the fruitful results of this unison, that seem to me to have given rise to the usage among foreign nations, of surrounding the caduceus with representations of serpents, as so many symbols of peace-it must be remembered, too, that on the caduceus, serpents are never represented as having crests.

CHAP. 13.

THE METHOD OF PREPARING COMMAGENUM. FOUR REMEDIES DERIVED FROM IT.

Having to make mention, in the present Book, of the eggs of the goose and the numerous uses to which they are applied, as also of the bird itself, it is our duty to award the honour to Commagene of a most celebrated preparation there made. This composition is prepared from goose-grease, a substance applied to many other well-known uses as well; but in the case of that which comes from Commagene, a part of Syria, the grease is first incorporated with cinnamon, cassia, white pepper, and the plant called “commagene,” and then placed in vessels and buried in the snow. The mixture has an agreeable smell, and is found extremely useful for cold shiverings, convulsions, heavy or sudden pains, and all those affections, in fact, which are treated with the class of remedies known as “acopa;” being equally an unguent and a medicament.

There is another method, also, of preparing it in Syria: the fat of the bird is preserved in manner already described, and there is added to it erysisceptrum, xylobalsamum, palm elate, and calamus, each in the same proportion as the grease; the whole being gently boiled some two or three times in wine. This preparation is made in winter, as in summer it will never thicken, except with the addition of wax. There are numerous other remedies, also, derived from the goose, as well as from the raven; a thing I am much surprised at, seeing that both the goose and the raven are generally said to be in a diseased state at the end of summer and the beginning of autumn.

Detailed table of contents

CHAP. 14. (4.)

REMEDIES DERIVED FROM THE DOO.

We have already spoken of the honours earned by the geese, when the Gauls were detected in their attempt to scale the Capitol. It is for a corresponding reason, also, that punishment is yearly inflicted upon the dogs, by crucifying them alive upon a gibbet of elder, between the Temple of Juventas and that of Summanus.

In reference to this last-mentioned animal, the usages of our forefathers compel us to enter into some further details. They considered the flesh of sucking whelps to be so pure a meat, that they were in the habit of using them as victims even in their expiatory sacrifices. A young whelp, too, is sacrificed to Genita Mana; and, at the repasts celebrated in honour of the gods, it is still the usage to set whelps' flesh on table; at the inaugural feasts, too, of the pontiffs, this dish was in common use, as we learn from the Comedies of Plautus. It is generally thought that for narcotic poisons there is nothing better than dogs' blood; and it would appear that it was this animal that first taught man the use of emetics. Other medicinal uses of the dog which are marvellously commended, I shall have occasion to refer to on the appropriate occasions.

Detailed table of contents

CHAP. 15.

REMEDIES CLASSIFIED ACCORDING TO THE DIFFERENT MALADIES. REMEDIES FOR INJURIES INFLICTED BY SERPENTS. REMEDIES DERIVED FROM MICE.

We will now resume the order originally proposed. For stings inflicted by serpents fresh sheeps'-dung, boiled in wine, is considered a very useful application: as also mice split asunder and applied to the wound. Indeed, these last animals are possessed of certain properties by no means to be despised, at the ascension of the planets more particularly, as already stated; the lobes increasing or decreasing in number, with the age of the moon, as the case may be. The magicians have a story that swine will follow any person who gives them a mouse's liver to eat, enclosed in a fig: they say, too, that it has a similar effect upon man, but that the spell may be destroyed by swallowing a cyathus of oil.

Detailed table of contents

CHAP. 16.

REMEDIES DERIVED FROM THE WEASEL.

There are two varieties of the weasel; the one, wild, larger than the other, and known to the Greeks as the “ictis:” its gall is said to be very efficacious as an antidote to the sting of the asp, but of a venomous nature in other respects. The other kind, which prowls about our houses, and is in the habit, Cicero tells us, of removing its young ones, and changing every day from place to place, is an enemy to serpents. The flesh of this last, preserved in salt, is given, in doses of one denarius, in three cyathi of drink to persons who have been stung by serpents: or else the maw of the animal is stuffed with coriander seed and dried, to be taken for the same purpose in wine. The young one of the weasel is still more efficacious for these purposes.

Detailed table of contents

CHAP. 17.

REMEDIES DERIVED FROM BUGS.

There are some things, of a most revolting nature, but which are recommended by authors with such a degree of assurance, that it would be improper to omit them, the more particularly as it is to the sympathy or antipathy of objects that remedies owe their existence. Thus the bug, for instance, a most filthy insect, and one the very name of which inspires us with loathing, is said to be a neutralizer of the venom of serpents, asps in particular, and to be a preservative against all kinds of poisons. As a proof of this, they tell us that the sting of an asp is never fatal to poultry, if they have eaten bugs that day; and that, if such is the case, their flesh is remarkably beneficial to persons who have been stung by serpents. Of the various recipes given in reference to these insects, the least revolting are the application of them externally to the wound, with the blood of a tortoise; the employment of them as a fumigation to make leeches loose their hold; and the administering of them to animals in drink when a leech has been accidentally swallowed. Some persons, however, go so far as to crush bugs with salt and woman's milk, and anoint the eyes with the mixture; in combination, too, with honey and oil of roses, they use them as an injection for the ears. Field-bugs, again, and those found upon the mallow, are burnt, and the ashes mixed with oil of roses as an injection for the ears.

As to the other remedial virtues attributed to bugs, for the cure of vomiting, quartan fevers, and other diseases, although we find recommendations given to swallow them in an egg, some wax, or in a bean, I look upon them as utterly unfounded, and not worthy of further notice. They are employed, however, for the treatment of lethargy, and with some fair reason, as they successfully neutralize the narcotic effects of the poison of the asp: for this purpose seven of them are administered in a cyathus of water, but in the case of children only four. In cases, too, of strangury, they have been injected into the urinary channel: so true it is that Nature, that universal parent, has engendered nothing without some powerful reason or other. In addition to these particulars, a couple of bugs, it is said, attached to the left arm in some wool that has been stolen from the shepherds, will effectually cure nocturnal fevers; while those recurrent in the daytime may be treated with equal success by enclosing the bugs in a piece of russet-coloured cloth. The scolopendra, on the other hand, is a great enemy to these insects; used in the form of a fumigation, it kills them.

CHAP. 18.

PARTICULARS RELATIVE TO THE ASP.

The sting of the asp takes deadly effect by causing torpor and drowsiness. Of all serpents, injuries inflicted by the asp are the most incurable; and their venom, if it comes in contact with the blood or a recent wound, produces instantaneous death. If, on the other hand, it touches an old sore, its fatal effects are not so immediate. Taken internally, in however large a quantity, the venom is not injurious, as it has no corrosive properties; for which reason it is that the flesh of animals killed by it may be eaten with impunity.

I should hesitate in giving circulation to a prescription for injuries inflicted by the asp, were it not that M. Varro, then in the eighty-third year of his age, has left a statement to the effect that it is a most efficient remedy for wounds inflicted by this reptile, for the person stung to drink his own urine.

Detailed table of contents

CHAP. 19.

REMEDIES DERIVED FROM THE BASILISK.

As to the basilisk, a creature which the very serpents fly from, which kills by its odour even, and which proves fatal to man by only looking upon him, its blood has been marvellously extolled by the magicians. This blood is thick and adhesive, like pitch, which it resembles also in colour: dissolved in water, they say, it becomes of a brighter red than that of cinnabar. They attribute to it also the property of ensuring success to petitions preferred to potentates, and to prayers even offered to the gods; and they regard it as a remedy for various diseases, and as an amulet preservative against all noxious spells. Some give it the name of “Saturn’s blood.”

Detailed table of contents

CHAP. 20.

REMEDIES DERIVED FROM THE DRAGON.

The dragon is a serpent destitute of venom. Its head, placed beneath the threshold of a door, the gods being duly propitiated by prayers, will ensure good fortune to the house, it is said. Its eyes, dried and beaten up with honey, form a liniment which is an effectual preservative against the terrors of spectres by night, in the case of the most timorous even. The fat adhering to the heart, attached to the arm with a deer's sinews in the skin of a gazelle, will ensure success in law-suits, it is said; and the first joint of the vertebræ will secure an easy access to persons high in office. The teeth, attached to the body with a deer's sinews in the skin of a roebuck, have the effect of rendering masters indulgent and potentates gracious, it is said.

But the most remarkable thing of all is a composition, by the aid of which the lying magicians profess to render persons invincible. They take the tail and head of a dragon, the hairs of a lion's forehead with the marrow of that animal, the foam of a horse that has won a race, and the claws of a dog's feet: these they tie up together in a deer's skin, and fasten them alternately with the sinews of a deer and a gazelle. It is, however, no better worth our while to refute such pretensions as these, than it would be to describe the alleged remedies for injuries inflicted by serpents, seeing that all these contrivances are so many evil devices to poison men's morals.

Dragon's fat will repel venomous creatures; an effect which is equally produced by burning the fat of the ichneumon. They will take to flight, also, at the approach of a person who has been rubbed with nettles bruised in vinegar.

Detailed table of contents

CHAP. 21.

REMEDIES DERIVED FROM THE VIPER.

The application of a viper's head, even if it be not the one that has inflicted the wound, is of infinite utility as a remedy. It is highly advantageous, too, to hold the viper that inflicted the injury on the end of a stick, over the steam of boiling water, for it will quite undo the mischief, they say. The ashes, also, of the viper, are considered very useful, employed as a liniment for the wound. According to what Nigidius tells us, serpents are compelled, by a sort of natural instinct, to return to the person who has been stung by them. The people of Scythia split the viper's head between the ears, in order to extract a small stone, which it swallows in its alarm, they say: others, again, use the head entire.

From the viper are prepared those tablets which are known as "theriaci" to the Greeks: for this purpose the animal is cut away three fingers' length from both the head and the tail, after which the intestines are removed and the livid vein adhering to the back-bone. The rest of the body is then boiled in a shallow pan, in water seasoned with dill, and the bones are taken out, and fine wheaten flour added; after which the preparation is made up into tablets, which are dried in the shade and are employed as an ingredient in numerous medicaments. I should remark, however, that this preparation, it would appear, can only be made from the viper. Some persons, after cleansing the viper in manner above described, boil down the fat, with one sextarius of olive oil, to one half. Of this preparation, when needed, three drops are added to some oil, with which mixture the body is rubbed, to repel the approach of all kinds of noxious animals.

Detailed table of contents

CHAP. 22.

REMEDIES DERIVED FROM THE OTHER SERPENTS.

In addition to these particulars, it is a well-known fact that for all injuries inflicted by serpents, and those even of an otherwise incurable nature, it is an excellent remedy to apply the entrails of the serpent itself to the wound; as also, that persons who have once swallowed a viper's liver, boiled, will never afterwards be attacked by serpents. The snake, too, is not venomous, except, indeed, upon certain days of the month when it is irritated by the action of the moon: it is a very useful plan to take it alive, and pound it in water, the wound inflicted by' it being fomented with the preparation. Indeed, it is generally supposed that this reptile is possessed of numerous other remedial properties, as we shall have occasion more fully to mention from time to time: hence it is that the snake is consecrated to Æsculapius. As for Democritus, he has given some monstrous preparations from snakes, by the aid of which the language of birds, he says, may be understood.

The Æsculapian snake was first brought to Rome from Epidaurus, but at the present day it is very commonly reared in our houses even; so much so, indeed, that if the breed were not kept down by the frequent conflagrations, it would be impossible to make head against the rapid increase of them. But the most beautiful of all the snakes are those which are of an amphibious nature. These snakes are known as "hydri," or water-snakes: in virulence their venom is inferior to that of no other class of serpents, and their liver is preserved as a remedy for the ill effects of their sting.

A pounded scorpion neutralizes the venom of the spotted lizard. From this last animal, too, there is a noxious preparation made; for it has been found that wine in which it has been drowned, covers the face of those who drink it with morpew. Hence it is that females, when jealous of a rival's beauty, are in the habit of stifling a spotted lizard in the unguents which they use. In such a case, the proper remedy is yolk of egg, honey, and nitre. The gall of a spotted lizard, beaten up in water, attracts weasels, they say.

CHAP. 23.

REMEDIES DERIVED FROM THE SALAMANDER.

But of all venomous animals it is the salamander that is by far the most dangerous; for while other reptiles attack individuals only, and never kill many persons at a time—not to mention the fact that after stinging a human being they are said to die of remorse, and the earth refuses to harbour them — the salamander is able to destroy whole nations at once, unless they take the proper precautions against it. For if this reptile happens to crawl up a tree, it infects all the fruit with its poison, and kills those who eat thereof by the chilling properties of its venom, which in its effects is in no way different from aconite. Nay, even more than this, if it only touches with its foot the wood upon which bread is baked, or if it happens to fall into a well, the same fatal effects will be sure to ensue. The saliva, too, of this reptile, if it comes in contact with any part of the body, the sole of the foot even, will cause the hair to fall off from the whole of the body. And yet the salamander, highly venomous as it is, is eaten by certain animals, swine for example; owing, no doubt, to that antipathy which prevails in the natural world.

From what we find stated, it is most probable, that, next to the animals which eat it, the best neutralizers of the poison of this reptile, are, cantharides taken in drink, or a lizard eaten with the food; other antidotes we have already mentioned, or shall notice in the appropriate place. As to what the magicians say, that it is proof against fire, being, as they tell us, the only animal that has the property of extinguishing fire, if it had been true, it would have been made trial of at Rome long before this. Sextius says that the salamander, preserved in honey and taken with the food, after removing the intestines, head, and feet, acts as an aphrodisiac: he denies also that it has the property of extinguishing fire.

CHAP. 24.

REMEDIES DERIVED FROM BIRDS FOR INJURIES IN- FLICTED BY SERPENTS.
REMEDIES DERIVED FROM THE VULTURE.

Among the birds that afford us remedies against serpents, it is the vulture that occupies the highest rank; the black vulture, it has been remarked, being less efficacious than the others. The smell of their feathers, burnt, will repel serpents, they say; and it has been asserted that persons who carry the heart of this bird about them will be safe, not only from serpents, but from wild beasts as well, and will have nothing to fear from the attacks of robbers or from the wrath of kings.

Detailed table of contents

CHAP. 25.

REMEDIES DERIVED FROM POULTRY.

The flesh of cocks and capons, applied warm the moment it has been plucked from the bones, neutralizes the venom of serpents; and the brains, taken in wine, are productive of a similar effect. The people of Parthia, however, prefer applying a hen's brains to the wound. Poultry broth, too, is highly celebrated as a cure, and is found marvellously useful in many other cases. Panthers and lions will never touch persons who have been rubbed with it, more particularly if it has been flavoured with garlic. The broth that is made of an old cock is more relaxing to the bowels; it is very good also for chronic fevers, numbness of the limbs, cold shiverings and maladies of the joints, pains also in the head, defluxions of the eyes, flatulency, sickness at stomach, incipient tenesmus, liver complaints, diseases of the kidneys, affections of the bladder, indigestion, and asthma. Hence there are several recipes for preparing this broth; it being most efficacious when boiled up with sea-cabbage, salted tunny, capers, parsley, the plant mercurialis, polypodium, or dill. The best plan, however, is to boil the cock or capon with the plants above-mentioned in three congii of water, down to three semi-sextarii; after which it should be left to cool in the open air, and given at the proper moment, just after an emetic has been administered.

And here I must not omit to mention one marvellous fact, even though it bears no reference to medicine: if the flesh of poultry is mingled with gold in a state of fusion, it will absorb the metal and consume it, thus showing that it acts as a poison upon gold. If young twigs are made up into a collar and put round a cock's neck, it will never crow.

Detailed table of contents

CHAP. 26.

REMEDIES DERIVED FROM OTHER BIRDS.

The flesh of pigeons also, or of swallows, used fresh and minced, is a remedy for injuries inflicted by serpents: the same, too, with the feet of a horned owl, burnt with the plant plumbago. While mentioning this bird, too, I must not forget to cite another instance of the impositions practised by the magicians: among other prodigious lies of theirs, they pretend that the heart of a horned owl, applied to the left breast of a woman while asleep, will make her disclose all her secret thoughts. They say, also, in addition to this, that persons who have it about them in battle will be sure to display valour. They describe, too, certain remedies made from the egg of this bird for the hair. But who, pray, has ever had the opportunity of seeing the egg of a horned owl, considering that it is so highly ominous to see the bird itself? And then besides, who has ever thought proper to make the experiment, and upon his hair more particularly? In addition to all this, the magicians go so far as to engage to make the hair curl by using the blood of the young of the horned owl.

What they tell us, too, about the bat, appears to belong to pretty much the same class of stories: if one of these animals is carried alive, three times round a house, they say, and then nailed outside of the window with the head downwards, it will have all the effects of a countercharm: they assert, also, that the bat is a most excellent preservative for sheepfolds, being first carried three times round them, and then hung up by the foot over the lintel of the door. The blood of the bat is also recommended by them as a sovereign remedy, in combination with a thistle, for injuries inflicted by serpents.

CHAP. 27.

REMEDIES FOR THE BITE OF THE PHALANGIUM. THE SEVERAL VARIETIES OF THAT INSECT, AND OF THE SPIDER.

Of the phalangium, an insect unknown to Italy, there are numerous kinds; one of which resembles the ant, but is much larger, with a red head, black as to the other parts of the body, and covered with white spots. Its sting is much more acute than that of the wasp, and it lives mostly in the vicinity of ovens and mills. The proper remedy is, to present before the eyes of the person stung another insect of the same description, a purpose for which they are preserved when found dead. Their husks also, found in a dry state, are beaten up and taken in drink for a similar purpose. The young of the weasel, too, as already stated, are possessed of a similar property. The Greeks give the name of "phalangion" also to a kind of spider, but they generally distinguish it by the surname of the "wolf." A third kind, also known as the "phalangium," is a spider with a hairy body, and a head of enormous size. When opened, there are found in it two small worms, they say: these, attached in a piece of deer's skin, before sunrise, to a woman's body, will prevent conception, according to what Cæcilius, in his Commentaries, says. This property lasts, however, for a year only; and, indeed, it is the only one of all the anti-conceptives that I feel myself at liberty to mention, in favour of some women whose fecundity, quite teeming with children, stands in need of some such respite.

There is another kind again, called "rhagion," similar to a black grape in appearance, with a very diminutive mouth, situate beneath the abdomen, and extremely short legs, which have all the appearance of not being fully developed. The bite of this last insect causes fully as much pain as the sting of the scorpion, and the urine of persons who are injured by it, presents filmy appearances like cobwebs. The asterion would be identical with it, were it not distinguished by white streaks upon the body: its bite causes failing in the knees. But worse than either of these last, is a blue spider, covered with black hair, and causing dimness of the sight and vomiting of a matter like cobwebs in appearance. A still more dangerous kind is one which differs only from the hornet, in form, in being destitute of wings, and the bite of which causes a wasting away of the system. The myrmecion in the head resembles the ant, has a black body spotted with white, and causes by its bite a pain like that attendant upon the sting of the wasp. Of the tetragnathius there are two varieties, the more noxious of which has two white streaks crossing each other on the middle of the head; its bite causes the mouth to swell. The other one is of an ashy colour, whitish on the posterior part of the body, and not so ready to bite.

The least noxious of all is the spider that is seen extending its web along the walls, and lying in wait for flies; it is of the same ashy colour as the last.

For the bite of all spiders, the best remedies are: a cock's brains, taken in

oxycrate with a little pepper; five ants, swallowed in drink; sheep's dung, applied in vinegar; and spiders of any kind, left to putrefy in oil. The bite of the shrewmouse is cured by taking lamb's rennet in wine; the ashes of a ram's foot with honey; or a young weasel, prepared in manner already mentioned by us when speaking of serpents. In cases where a shrewmouse has bitten beasts of burden, a mouse,. fresh caught, is applied to the wound with oil, or a bat's gall with vinegar. The shrew-mouse itself too, split asunder and applied to the wound, is a cure for its bite; indeed, if the animal is with young when the injury is inflicted, it will instantly burst asunder. The best plan is to apply the mouse itself which has inflicted the bite, but others are commonly kept for this purpose, either steeped in oil or coated with clay. Another remedy, again, for its bite is the earth taken from the rut made by a cart-wheel; for this animal, it is said, owing to a certain torpor which is natural to it, will never cross a rut made by a wheel.

Detailed table of contents

CHAP. 28.

REMEDIES DERIVED FROM THE STELLIO OR SPOTTED LIZARD.

The stellio, in its turn, is said to have the greatest antipathy to the scorpion; so much so indeed, that the very sight of it strikes terror in that reptile, and a torpor attended with cold sweats; hence it is that this lizard is left to putrefy in oil, as a liniment for injuries inflicted by the scorpion. Some persons boil down the oil with litharge, and make a sort of plaster of it to apply to the wound. The Greeks give the name of “colotes” to this lizard, as also “ascalabotes,” and “galeotes:” it is never found in Italy, and is covered with small spots, utters a shrill, piercing noise, and lives on food; characteristics, all of them, foreign to the stellio of Italy.

Detailed table of contents

CHAP. 29.

REMEDIES DERIVED FROM VARIOUS INSECTS.

Poultry dung, too, is good as an application for the sting of the scorpion; a dragon's liver also; a lizard or mouse split asunder; or else the scorpion itself, either applied to the wound, grilled and eaten, or taken in two cyathi of undiluted wine. One peculiarity of the scorpion is, that it never stings the palm of the hand, and never touches any parts of the body but those covered with hair. Any kind of pebble, applied to the wound on the side which has lain next to the ground, will alleviate the pain. A potsherd too, covered with earth on any part of it, and applied just as it is found, will effect a cure, it is said — the person, however, who applies it must not look behind him, and must be equally careful that the sun does not shine upon him. Earth-worms also, are pounded and applied to the wound; in addition to which, they form ingredients in numerous other medicaments, being kept in honey for the purpose.

For injuries inflicted by bees, wasps, hornets, and leeches, the owlet is considered a very useful remedy; persons, too, who carry about them the beak of the woodpecker of Mars are never injured by any of these creatures. The smaller kinds of locusts also, destitute of wings and known as “attelebi,” are a good remedy for the sting of the scorpion.

There is a kind of venomous ant, by no means common in Italy; Cicero calls it “solipuga,” and in Bætica it is known as “salpuga.” The proper remedy for its venom and that of all kinds of ants is a bat's heart. We have already stated that cantharides are an antidote to the salamander.

Detailed table of contents

CHAP. 30.

REMEDIES DERIVED :FROM CANTHARIDES.

But with reference to cantharides, there has been considerable controversy on the subject, seeing that, taken internally, they are a poison, attended with excruciating pains in the bladder. Cossinus, a Roman of the Equestrian order, well known for his intimate friendship with the Emperor Nero, being attacked with lichen, that prince sent to Egypt for a physician to cure him; who recommending a potion prepared from cantharides, the patient was killed in consequence. There is no doubt, however, that applied externally they are useful, in combination with juice of Taminian grapes, and the suet of a sheep or she-goat. As to the part of the body in which the poison of the insect is situate, authors are by no means agreed. Some fancy that it exists in the feet and head, while others, again, deny it; indeed the only point that has been well ascertained is, that the wings are the only antidote to their venom, wherever it may be situate.

Cantharides are produced from a small grub, found more particularly in the spongy excrescences which grow on the stem of the dog-rose, and still more abundantly upon the ash. Other kinds, again, are found upon the white rose, but they are by no means so efficacious. The most active of all in their properties, are those which are spotted with yellow streaks running transversely across the wings, and are plump and well-filled. Those which are small, broad, and hairy, are not so powerful in their operation, and the least useful of all are those which are thin and shrivelled, and present one uniform colour. They are put in a small earthen pot, not coated with pitch, and stopped at the mouth with a linen cloth, a layer of full-blown roses being placed upon them; they are then suspended over vinegar boiled with salt, until the steam has penetrated the cloth and stifled them, after which they are put by for use. They have a caustic effect upon the skin, and cover the ulcerations with a crust; a property which belongs also to the pine-caterpillar found upon the pitch-tree, and to the buprestis, both of which are prepared in a similar manner.

All these insects are extremely efficacious for the cure of leprosy and lichens. It is said, too, that they act as an emmenagogue and diuretic, for which last reason Hippocrates used to prescribe them for dropsy. Cato of Utica was reproached with selling poison, because, when disposing of a royal property by auction, he sold a quantity of cantharides, at the price of sixty thousand sesterces. (5.) We may here remark, too, that it was on the same occasion that some ostrich fat was sold, at the price of thirty thousand sesterces, a substance which is preferable to goose-grease in every respect.

CHAP. 31.

VARIOUS COUNTER-POISONS.

We have already spoken of various kinds of poisonous honey: the antidote employed for it is honey in which the bees have been stifled. This honey, too, taken in wine, is a remedy for indispositions caused by eating fish.

Detailed table of contents

CHAP. 32.

REMEDIES FOR THE BITE OF THE MAD DOG.

When a person has been bitten by a mad dog, he may be preserved from hydrophobia by applying the ashes of a dog's head to the wound. All ashes of this description, we may here remark once for all, are prepared in the same method; the substance being placed in a new earthen vessel well covered with potter's clay, and put into a furnace. These ashes, too, are very good, taken in drink, and hence some recommend the head itself to be eaten in such cases. Others, again, attach to the body of the patient a maggot, taken from the carcase of a dead dog; or else place the menstruous blood of a bitch, in a linen cloth, beneath his cup, or insert in the wound ashes of hairs from the tail of the dog that inflicted the bite. Dogs will fly from any one who has a dog's heart about him, and they will never bark at a person who carries a dog's tongue in his shoe, beneath the great toe, or the tail of a weasel which has been set at liberty after being deprived of it. There is beneath the tongue of a mad dog a certain slimy spittle, which, taken in drink, is a preventive of hydrophobia: but much the most useful plan is, to take the liver of the dog that has inflicted the injury, and eat it raw, if possible; should that not be the case, it must be cooked in some way or other, or else a broth must be taken, prepared from the flesh.

There is a small worm in a dog's tongue, known as "lytta" to the Greeks: if this is removed from the animal while a pup, it will never become mad or lose its appetite. This worm, after being carried thrice round a fire, is given to persons who have been bitten by a mad dog, to prevent them from becoming mad. This madness, too, is prevented by eating a cock's brains; but the virtue of these brains lasts for one year only, and no more. They say, too, that a cock's comb, pounded, is highly efficacious as an application to the wound; as also, goose-grease, mixed with honey. The flesh also of a mad dog is sometimes salted, and taken with the food, as a remedy for this disease. In addition to this, young puppies of the same sex as the dog that has inflicted the injury, are drowned in water, and the person who has been bitten eats their liver raw. The dung of poultry, provided it is of a red colour, is very useful, applied with vinegar; the ashes, too, of the tail of a shrew-mouse, if the animal has survived and been set at liberty; a clod from a swallow's nest, applied with vinegar; the young of a swallow, reduced to ashes; or the skin or old slough of a serpent that has been cast in spring, beaten up with a male crab in wine: this slough, I would remark, put away by itself in chests and drawers, destroys moths.

So virulent is the poison of the mad dog, that its very urine even, if trod upon, is injurious, more particularly if the person has any ulcerous sores about him. The proper remedy in such case is to apply horse-dung, sprinkled with

vinegar, and warmed in a fig. These marvellous properties of the poison will occasion the less surprise, when we remember that, “a stone bitten by a dog” has become a proverbial expression for discord and variance. Whoever makes water where a dog has previously watered, will be sensible of numbness in the loins, they say.

The lizard known by some persons as the “seps,” and by others as the “chalcidice,” taken in wine, is a cure for its own bite.

Detailed table of contents

CHAP. 33.

REMEDIES FOR THE OTHER POISONS.

Where persons have been poisoned by noxious preparations from the wild weasel, the proper remedy is the broth of an old cock, taken in considerable quantities. This broth, too, is particularly good, taken as a counter-poison for aconite, in combination with a little salt. Poultry dung — but the white part only — boiled with hyssop, or with honied wine, is an excellent antidote to the poison of fungi and of mushrooms: it is a cure also for flatulency and suffocations; a thing the more to be wondered at, seeing that if any other living creature only tastes this dung, it is immediately attacked with griping pains and flatulency. Goose blood, taken with an equal quantity of olive oil, is an excellent neutralizer of the venom of the seahare: it is kept also as an antidote for all kinds of noxious drugs, made up into lozenges with red earth of Lemnos and juice of white-thorn, five drachmæ of the lozenges being taken in three cyathi of water. The same property belongs also to the young of the weasel, prepared in manner already mentioned.

Lambs' rennet is an excellent antidote to all noxious preparations; the blood, also, of ducks from Pontus; for which reason it is preserved in a dry state, and dissolved in wine when wanted, some persons being of opinion that the blood of the female bird is the most efficacious. In a similar manner, the crop of a stork acts as an universal counter-poison; and so does sheep's rennet. A broth made from ram's flesh is particularly good as a remedy for cantharides: sheep's milk also, taken warm; this last being very useful in cases where persons have drunk an infusion of aconite, or have swallowed the buprestis in drink. The dung of wood-pigeons is particularly good taken internally as an antidote to quicksilver; and for narcotic poisons the common weasel is kept dried, and taken internally, in doses of two drachmæ.

Detailed table of contents

CHAP. 34. (6.)

REMEDIES FOR ALOPECY.

Where the hair has been lost through alopecy, it is made to grow again by using ashes of burnt sheep's dung, with oil of cyprus and honey; or else the hoof of a mule of either sex, burnt to ashes and mixed with oil of myrtle. In addition to these substances, we find our own writer, Varro, mentioning mousedung, which he calls "muscerda," and the heads of flies, applied fresh, the part being first rubbed with a fig-leaf. Some recommend the blood of flies, while others, again, apply ashes of burnt flies for ten days, in the proportion of one part of the ashes to two of ashes of papyrus or of nuts. In other cases, again, we find ashes of burnt flies kneaded up with woman's milk and cabbage, or, in some instances, with honey only. It is generally believed that there is no creature less docile or less intelligent than the fly; a circumstance which makes it all the more marvellous that at the sacred games at Olympia, immediately after the immolation of the bull in honour of the god called "Myiodes," whole clouds of them take their departure from that territory. A mouse's head or tail, or, indeed, the whole of the body, reduced to ashes, is a cure for alopecy, more particularly when the loss of the hair has been the result of some noxious preparation. The ashes of a hedge-hog, mixed with honey, or of its skin, applied with tar, are productive of a similar effect. The head, too, of this last animal, reduced to ashes, restores the hair to scars upon the body; the place being first prepared, when this cure is made use of, with a razor and an application of mustard: some persons, however, prefer vinegar for the purpose. All the properties attributed to the hedge-hog are found in the porcupine in a still higher degree.

A lizard burnt, as already mentioned, with the fresh root of a reed, cut as fine as possible, to facilitate its being reduced to ashes, and then mixed with oil of myrtle, will prevent the hair from coming off. For all these purposes green lizards are still more efficacious, and the remedy is rendered most effectual, when salt is added, bears' grease, and pounded onions. Some persons boil ten green lizards in ten sextarii of oil, and content themselves with rubbing the place with the mixture once a month. Alopecy is also cured very speedily with the ashes of a viper's skin, or by an application of fresh poultry dung. A raven's egg, beaten up in a copper vessel and applied to the head, previously shaved, imparts a black colour to the hair; care must be taken, however, to keep some oil in the mouth till the application is quite dry, or else the teeth will turn black as well. The operation must be performed also in the shade, and the liniment must not be washed off before the end of three days. Some persons employ the blood and brains of a raven, in combination with red wine; while others, again, boil down the bird, and put it, at bedtime, in a vessel made of lead. With some it is the practice, for the cure of alopecy,

to apply bruised cantharides with tar, the skin being first prepared with an application of nitre: — it should be remembered, however, that cantharides are possessed of caustic properties, and due care must be taken not to let them eat too deep into the skin. For the ulcerations thus produced, it is recommended to use applications made of the heads, gall, and dung of mice, mixed with hellebore and pepper.

Detailed table of contents

CHAP. 35.

REMEDIES FOR LICE AND FOR PORRIGO.

Nits are destroyed by using dogs' fat, eating serpents cooked like eels, or else taking their sloughs in drink. Porrigo is cured by applying sheep's gall with Cimolian chalk, and rubbing the head with the mixture till dry.

Detailed table of contents

CHAP. 36.

REMEDIES FOR HEAD-ACHE AND FOR WOUNDS ON THE HEAD.

A good remedy for head-ache are the heads taken from the snails which are found without shells, and in an imperfect state. In these heads there is found a hard stony substance, about as large as a common pebble: on being extracted from the snail, it is attached to the patient, the smaller snails being pounded and applied to the forehead. Wool-grease, too, is used for a similar purpose; the bones of a vulture's head, worn as an amulet; or the brains of that bird, mixed with oil and cedar resin, and applied to the head and introduced into the nostrils. The brains of a crow or owlet, are boiled and taken with the food: or a cock is put into a coop, and kept without food a day and a night, the patient submitting to a similar abstinence, and attaching to his head some feathers plucked from the neck or the comb of the fowl. The ashes, too, of a weasel are applied in the form of a liniment; a twig is taken from a kite's nest, and laid beneath the patient's pillow; or a mouse's skin is burnt, and the ashes applied with vinegar: sometimes, also, the small bone is extracted from the head of a snail that has been found between two cart ruts, and after being passed through a gold ring, with a piece of ivory, is attached to the patient in a piece of dog's skin; a remedy well known to most persons, and always used with success.

For fractures of the cranium, cobwebs are applied, with oil and vinegar; the application never coming away till a cure has been effected. Cobwebs are good, too, for stopping the bleeding of wounds made in shaving. Discharges of blood from the brain are arrested by applying the blood of a goose or duck, or the grease of those birds with oil of roses. The head of a snail cut off with a reed, while feeding in the morning, at full moon more particularly, is attached to the head in a linen cloth, with an old thrum, for the cure of headache; or else a liniment is made of it, and applied with white wax to the forehead. Dogs' hairs are worn also, attached to the forehead in a cloth.

Detailed table of contents

CHAP. 37.

REMEDIES FOR AFFECTIONS OF THE EYELIDS.

A crow's brains, taken with the food, they say, will make the eyelashes grow; or else wool-grease, applied with warmed myrrh, by the aid of a fine probe. A similar result is promised by using the following preparation: burnt flies and ashes of mouse-dung are mixed in equal quantities, to the amount of half a denarius in the whole; two sixths of a denarius of antimony are then added, and the mixture is applied with wool-grease. For the same purpose, also, the young ones of a mouse are beaten up, in old wine, to the consistency of the strengthening preparations known as "acopa." When eyelashes are plucked out that are productive of inconvenience, they are prevented from growing again by using a hedge-hog's gall; the liquid portion, also, of a spotted lizard's eggs; the ashes of a burnt salamander; the gall of a green lizard, mixed with white wine, and left to thicken to the consistency of honey in a copper vessel in the sun; the ashes of a swallow's young, mixed with the milky juice of tithymalos; or else the slime of snails.

[Detailed table of contents](#)

CHAP. 38.

REMEDIES FOR DISEASES OF THE EYES.

According to what the magicians say, glaucoma may be cured by using the brains of a puppy seven days old; the probe being inserted in the right side [of the eye], if it is the right eye that is being operated on, and in the left side, if it is the left. The fresh gall, too, of the asio is used, a bird belonging to the owlet tribe, with feathers standing erect like ears. Apollonius of Pitane used to prefer dog's gall, in combination with honey, to that of the hyæna, for the cure of cataract, as also of albugo. The heads and tails of mice, reduced to ashes and applied to the eyes, improve the sight, it is said; a result which is ensured with even greater certainty by using the ashes of a dormouse or wild mouse, or else the brains or gall of an eagle. The ashes and fat of a field-mouse, beaten up with Attic honey and antimony, are remarkably useful for watery eyes — what this antimony is, we shall have occasion to say when speaking of metals.

For the cure of cataract, the ashes of a weasel are used, as also the brains of a lizard or swallow. Weasels, boiled and pounded, and so applied to the forehead, allay defluxions of the eyes, either used alone, or else with fine flour or with frankincense. Employed in a similar manner, they are very good for sun-stroke, or in other words, for injuries inflicted by the sun. It is a remarkably good plan, too, to burn these animals alive, and to use their ashes, with Cretan honey, as a liniment for films upon the eyes. The cast-off slough of the asp, with the fat of that reptile, forms an excellent ointment for improving the sight in beasts of burden. To burn a viper alive in a new earthen vessel, with one cyathus of fennel juice, and a single grain of frankincense, and then to anoint the eyes with the mixture, is remarkably good for cataract and films upon the eyes; the preparation being generally known as "echeon." An eye-salve, too, is prepared, by leaving a viper to putrefy in an earthen pot, and bruising the maggots that breed in it with saffron. A viper, too, is burnt in a vessel with salt, and the preparation is applied to the tip of the tongue, to improve the eyesight, and to act generally as a corrective of the stomach and other parts of the body. This salt is given also to sheep, to preserve them in health, and is used as an ingredient in antidotes to the venom of serpents.

Some persons, again, use vipers as an article of food: when this is done, it is recommended, the moment they are killed, to put some salt in the mouth and let it melt there; after which, the body must be cut away to the length of four fingers at each extremity, and, the intestines being first removed, the remainder boiled in a mixture of water, oil, salt, and dill. When thus prepared, they are either eaten at once, or else kneaded in a loaf, and taken from time to time as wanted. In addition to the above-mentioned properties, viper-broth cleanses all parts of the body of lice, and removes itching sensations as well

upon the surface of the skin. The ashes, also, of a viper's head, used by themselves, are evidently productive of considerable effects; they are employed very advantageously in the form of a liniment for the eyes; and so, too, is viper's fat. I would not make so bold as to advise what is strongly recommended by some, the use, namely, of vipers' gall; for that, as already stated on a more appropriate occasion, is nothing else but the venom of the serpent. The fat of snakes, mixed with verdigrease, heals ruptures of the cuticle of the eyes; and the skin or slough that is cast off in spring, employed as a friction for the eyes, improves the sight. The gall of the boa is highly vaunted for the cure of albugo, cataract, and films upon the eyes, and the fat is thought to improve the sight.

The gall of the eagle, which tests its young, as already stated, by making them look upon the sun, forms, with Attic honey, an eye-salve which is very good for the cure of webs, films, and cataracts of the eye. A vulture's gall, too, mixed with leek-juice and a little honey, is possessed of similar properties; and the gall of a cock, dissolved in water, is employed for the cure of argema and albugo: the gall, too, of a white cock, in particular, is recommended for cataract. For shortsighted persons, the dung of poultry is recommended as a liniment, care being taken to use that of a reddish colour only. A hen's gall, too, is highly spoken of, and the fat in particular, for the cure of pustules upon the pupils, a purpose for which hens are expressly fattened. This last substance is marvellously useful for ruptures of the coats of the eyes, incorporated with the stones known as schistos and hæmatites. Hens' dung, too, but only the white part of it, is kept with old oil in boxes made of horn, for the cure of white specks upon the pupil of the eye. While mentioning this subject, it is worthy of remark, that peacocks swallow their dung, it is said, as though they envied man the various uses of it. A hawk, boiled in oil of roses, is considered extremely efficacious as a liniment for all affections of the eyes, and so are the ashes of its dung, mixed with Attic honey. A kite's liver, too, is highly esteemed; and pigeons' dung, diluted with vinegar, is used as an application for fistulas of the eye, as also for albugo and marks upon that organ. Goose gall and duck's blood are very useful for contusions of the eyes, care being taken, immediately after the application, to anoint them with a mixture of woolgrease and honey. In similar cases, too, gall of partridges is used, with an equal quantity of honey; but where it is only wanted to improve the sight, the gall is used alone. It is generally thought, too, upon the authority of Hippocrates, that the gall to be used for these purposes should be kept in a silver box.

Partridges' eggs, boiled in a copper vessel, with honey, are curative of ulcers of the eyes, and of glaucoma. For the treatment of blood-shot eyes, the blood of pigeons, ring-doves, turtle-doves, and partridges is remarkably useful; but that of the male pigeon is generally looked upon as the most efficacious. For this purpose, a vein is opened beneath the wing, it being warmer than the rest of the blood, and consequently more beneficial. After it

is applied, a compress, boiled in honey, should be laid upon it, and some greasy wool, boiled in oil and wine. Nyctalopy, too, is cured by using the blood of these birds, or the liver of a sheep — the most efficacious being that of a tawny sheep — as already stated by us when speaking of goats. A decoction, too, of the liver is recommended as a wash for the eyes, and, for pains and swellings in those organs, the marrow, used as a liniment. The eyes of a horned owl, it is strongly asserted, reduced to ashes and mixed in an eye-salve, will improve the sight. Albugo is made to disappear by using the dung of turtle-doves, snails burnt to ashes, and the dung of the cenchris, a kind of hawk, according to the Greeks. All the substances above mentioned, used in combination with honey, are curative of argema: honey, too, in which the bees have died, is remarkably good for the eyes.

A person who has eaten the young of the stork will never suffer from ophthalmia for many years to come, it is said; and the same when a person carries about him the head of a dragon: it is stated, too, that the fat of this last-named animal, applied with honey and old oil, will disperse incipient films of the eyes. The young of the swallow are blinded at full moon, and the moment their sight is restored, their heads are burnt, and the ashes are employed, with honey, to improve the sight, and for the cure of pains, ophthalmia, and contusions of the eyes.

Lizards, also, are employed in numerous ways as a remedy for diseases of the eyes. Some persons enclose a green lizard in a new earthen vessel, together with nine of the small stones known as “cinædia,” which are usually attached to the body for tumours in the groin. Upon each of these stones they make nine marks, and remove one from the vessel daily, taking care, when the ninth day is come, to let the lizard go, the stones being kept as a remedy for affections of the eyes. Others, again, blind a green lizard, and after putting some earth beneath it, enclose it in a glass vessel, with some small rings of solid iron or gold. When they find, by looking through the glass, that the lizard has recovered its sight, they set it at liberty, and keep the rings as a preservative against ophthalmia. Others employ the ashes of a lizard’s head as a substitute for antimony, for the treatment of eruptions of the eyes. Some recommend the ashes of the green lizard with a long neck that is usually found in sandy soils, as an application for incipient defluxions of the eyes, and for glaucoma. They say, too, that if the eyes of a weasel are extracted with a pointed instrument, its sight will return; the same use being made of it as of the lizards and rings above mentioned. The right eye of a serpent, worn as an amulet, is very good, it is said, for defluxions of the eyes, due care being taken to set the serpent at liberty after extracting the eye. For continuous watering of the eyes, the ashes of a spotted lizard’s head, applied with antimony, are remarkably efficacious.

The cobweb of the common fly-spider, that which lines its hole more particularly, applied to the forehead across the temples, in a compress of some kind or other, is said to be marvellously useful for the cure of defluxions of

the eyes: the web must be taken, however, and applied by the hands of a boy who has not arrived at the years of puberty; the boy, too, must not show himself to the patient for three days, and during those three days neither of them must touch the ground with his feet uncovered. The white spider with very elongated, thin, legs, beaten up in old oil, forms an ointment which is used for the cure of albugo. The spider, too, whose web, of remarkable thickness, is generally found adhering to the rafters of houses, applied in a piece of cloth, is said to be curative of defluxions of the eyes. The green scarabæus has the property of rendering the sight more piercing of those who gaze upon it: hence it is that the engravers of precious stones use these insects to steady their sight.

CHAP. 39.

REMEDIES FOR PAINS AND DISEASES OF THE EARS.

A sheep's gall, mixed with honey, is a good detergent of the ears. Pains in those organs are allayed by injecting a bitch's milk; and hardness of hearing is removed by using dogs' fat, with wormwood and old oil, or else goose-grease. Some persons add juice of onions and of garlic, in equal proportions. The eggs, too, of ants are used, by themselves, for this purpose; these insects being possessed, in fact, of certain medicinal properties, and bears, it is well known, curing themselves when sick, by eating them as food. Goose-grease, and indeed that of all birds, is prepared by removing all the veins and leaving the fat, in a new, shallow, earthen vessel, well covered, to melt in the sun, some boiling water being placed beneath it; which done, it is passed through linen strainers, and is then put by in a cool spot, in a new earthen vessel, for keeping: with the addition of honey it is less liable to turn rancid. Ashes of burnt mice, injected with honey or boiled with oil of roses, allay pains in the ears. In cases where an insect has got into the ears, a most excellent remedy is found in an injection of mouse gall, diluted with vinegar; where, too, water has made its way into the passages of the ear, goose-grease is used, in combination with juice of onions. Some persons skin a dormouse, and after removing the intestines boil the body in a new vessel with honey. Medical men, however, prefer boiling it down to one-third with nard, and recommend it to be kept in that state, and to be warmed when wanted, and injected with a syringe. It is a well-known fact, that this preparation is an effectual remedy for the most desperate maladies of the ears the same, too, with an injection of earth-worms boiled with goose-grease. The red worms, also, that are found upon trees, beaten up with oil, are a most excellent remedy for ulcerations and ruptures of the ears. Lizards, which have been suspended for some time and dried, with salt in the mouth, are curative of contusions of the ears, and of injuries inflicted by blows: the most efficacious for this purpose are those which have ironcoloured spots upon the skin, and are streaked with lines along the tail.

Millepedes, known also as "centipedes" or "multipedes," are insects belonging to the earth-worm genus, hairy, with numerous feet, forming curves as they crawl, and contracting themselves when touched: the Greeks give to this insect the name of "oniscos," others, again, that of "tylos." Boiled with leek-juice in a pomegranate rind, it is highly efficacious, they say, for pains in the ears; oil of roses being added to the preparation, and the mixture injected into the ear opposite to the one affected. As for that kind which does not describe a curve when moving, the Greeks give it the name of "seps," while others, again, call it "scolopendra;" it is smaller than the former one, and is injurious. The snails which are commonly used as food, are applied to the ears

with myrrh or powdered frankincense; and those with a small, broad, shell are employed with honey as a liniment for fractured ears. Old sloughs of serpents, burnt in a heated potsherd and mixed with oil of roses, are used as an injection for the ears, which is considered highly efficacious for all affections of those organs, and for offensive odours arising there from in particular. In cases where there is suppuration of the ears, vinegar is used, and it is still better if goat's gall, ox-gall, or that of the sea tortoise, is added. This slough, however, is good for nothing when more than a year old; the same, too, when it has been drenched with rain, as some think. The thick pulp of a spider's body, mixed with oil of roses, is also used for the ears; or else the pulp applied by itself with saffron or in wool: a cricket, too, is dug up with some of its earth, and applied. Nigidius attributes great virtues to this insect, and the magicians still greater, and all because it walks backwards, pierces the earth, and chirrups by night! The mode of catching it is by throwing an ant, made fast with a hair, into its hole, the dust being first blown away to prevent it from concealing itself: the moment it seizes the ant, it is drawn out.

The dried craw of poultry, a part that is generally thrown away, is beaten up in wine, and injected warm, for suppurations of the ears; the same, too, with the grease of poultry.

On pulling off the head of a black beetle, it yields a sort of greasy substance, which, beaten up with rose oil, is marvellously good, they say, for affections of the ears: care must be taken, however, to remove the wool very soon, or else this substance will be speedily transformed into an animal, in the shape of a small grub. Some writers assert that two or three of these insects, boiled in oil, are extremely efficacious for the ears; and that they are good, beaten up and applied in linen, for contusions of those organs.

This insect, also, is one of those that are of a disgusting character; but I am obliged, by the admiration which I feel for the operations of Nature, and for the careful researches of the ancients, to enter somewhat more at large upon it on the present occasion. Their writers have described several varieties of it; the soft beetle, for instance, which, boiled in oil, has been found by experience to be a very useful liniment for warts. Another kind, to which they have given the name of "mylœcon," is generally found in the vicinity of mills: deprived of the head, it has been found to be curative of leprosy — at least Musa and Picton have cited instances to that effect. There is a third kind, again, odious for its abominable smell, and tapering at the posterior extremities. Used in combination with pisselæon, it is curative, they say, of ulcers of a desperate nature, and, if kept applied for one-and-twenty days, for scrofulous sores and inflamed tumours. The legs and wings being first removed, it is employed for the cure of bruises, contusions, cancerous sores, itch-scabs, and boils — remedies, all of them, quite disgusting even to hear of. And yet, by Hercules! Diodorus tells us that he has administered this remedy internally, with resin and honey, for jaundice and hardness of breathing; such unlimited power has the medical art to prescribe as a remedy whatever it

thinks fit!

Physicians who keep more within bounds, recommend the ashes of these insects to be kept for these various purposes in a box made of horn; or else that they should be bruised and injected in a lavement for hardness of breathing and catarrhs. At all events, that, applied externally, they extract foreign substances adhering to the flesh, is a fact well known.

Honey, too, in which the bees have died, is remarkably useful for affections of the ears. Pigeons' dung, applied by itself, or with barley-meal or oat-meal, reduces imposthumes of the parotid glands; a result which is equally obtained by injecting into the ear an owl's brains or liver, mixed with oil, or by applying the mixture to the parotid glands; also, by applying millepedes with one-third part of resin; by using crickets in the form of a liniment; or by wearing crickets attached to the body as an amulet. The other kinds of maladies, and the several remedies for them, derived from the same animals or from others of the same class, we shall describe in the succeeding Book.

SUMMARY. — Remedies, narratives, and observations, six hundred and twenty-one.

ROMAN AUTHORS QUOTED. — M. Varro, L. Piso, Flaccus Verrius, Antias, Nigidius, Cassius Hemina, Cicero, Plautus, Celsus, Sextius Niger who wrote in Greek, Cæcilius the physician, Metellus Scipio, the Poet Ovid, Licinius Macer.

FOREIGN AUTHORS QUOTED. — Homer, Aristotle, Orpheus, Palæphatus, Democritus, Anaxilæus.

MEDICAL AUTHORS QUOTED. — Botrys, Apollodorus, Archidemus, Aristogenes, Xenocrates, Democrates, Diodorus, Chrysippus the philosopher, Horus, Nicander, Apollonius Of Pitane.

CHAP. 1. (1.)

THE ORIGIN OF THE MAGIC ART.

IN former parts of this work, I have had occasion more than. once, when the subject demanded it, to refute the impostures of the magic art, and it is now my intention to continue still further my exposure thereof. Indeed, there are few subjects on which more might be profitably said, were it only that, being, as it is, the most deceptive of all known arts, it has exercised the greatest influence in every country and in nearly every age. And no one can be surprised at the extent of its influence and authority, when he reflects that by its own energies it has embraced, and thoroughly amalgamated with itself; the three other sciences which hold the greatest sway upon the mind of man.

That it first originated in medicine, no one entertains a doubt; or that, under the plausible guise of promoting health, it insinuated itself among mankind, as a higher and more holy branch of the medical art. Then, in the next place, to promises the most seductive and the most flattering, it has added all the resources of religion, a subject upon which, at the present day, man is still entirely in the dark. Last of all, to complete its universal sway, it has incorporated with itself the astrological art; there being no man who is not desirous to know his future destiny, or who is not ready to believe that this knowledge may with the greatest certainty be obtained, by observing the face of the heavens. The senses of men being thus enthralled by a three-fold bond, the art of magic has attained an influence so mighty, that at the present day even, it holds sway throughout a great part of the world, and rules the kings of kings in the East.

Detailed table of contents

CHAP. 2.

WHEN AND WHERE THE ART OF MAGIC ORIGINATED: BY WHAT PERSONS IT WAS FIRST PRACTISED.

There is no doubt that this art originated in Persia, under Zoroaster, this being a point upon which authors are generally agreed; but whether there was only one Zoroaster, or whether in later times there was a second person of that name, is a matter which still remains undecided. Eudoxus, who has endeavoured to show that of all branches of philosophy the magic art is the most illustrious and the most beneficial, informs us that this Zoroaster existed six thousand years before the death of Plato, an assertion in which he is supported by Aristotle. Hermippus, again, an author who has written with the greatest exactness on all particulars connected with this art, and has commented upon the two millions of verses left by Zoroaster, besides completing indexes to his several works, has left a statement, that Agonaces was the name of the master from whom Zoroaster derived his doctrines, and that he lived five thousand years before the time of the Trojan War. The first thing, however, that must strike us with surprise, is the fact that this art, and the traditions connected with it, should have survived for so many ages, all written commentaries thereon having perished in the meanwhile; and this, too, when there was no continuous succession of adepts, no professors of note, to ensure their transmission.

For how few there are, in fact, who know anything, even by hearsay, about the only professors of this art whose names have come down to us, Apusorus and Zaratus of Media, Marmarus and Arabantiphocus of Babylonia, and Tarmoendas of Assyria, men who have left not the slightest memorials of their existence. But the most surprising thing of all is, that Homer should be totally silent upon this art in his account of the Trojan War, while in his story of the wanderings of Ulysses, so much of the work should be taken up with it, that we may justly conclude that the poem is based upon nothing else; if, indeed, we are willing to grant that his accounts of Proteus and of the songs of the Sirens are to be understood in this sense, and that the stories of Circe and of the summoning up of the shades below, bear reference solely to the practices of sorcerers. And then, too, to come to more recent times, no one has told us how the art of sorcery reached Telmessus, a city devoted to all the services of religion, or at what period it came over and reached the matrons of Thessaly; whose name has long passed, in our part of the world, as the appellation of those who practise an art, originally introduced among themselves even, from foreign lands. For in the days of the Trojan War, Thessaly was still contented with such remedies as she owed to the skill of Chiron, and her only lightnings were the lightnings hurled by Mars. Indeed, for my own part, I am surprised that the imputation of magical practices should have so strongly attached to the people once under the sway of

Achilles, that Menander even, a man unrivalled for perception in literary knowledge, has entitled one of his Comedies "The Thessalian Matron," and has therein described the devices practised by the females of that country in bringing down the moon from the heavens. I should have been inclined to think that Orpheus had been the first to introduce into a country so near his own, certain magical superstitions based upon the practice of medicine, were it not the fact that Thrace, his native land, was at that time totally a stranger to the magic art.

The first person, so far as I can ascertain, who wrote upon magic, and whose works are still in existence, was Osthanes, who accompanied Xerxes, the Persian king, in his expedition against Greece. It was he who first disseminated, as it were, the germs of this monstrous art, and tainted therewith all parts of the world through which the Persians passed. Authors who have made diligent enquiries into this subject, make mention of a second Zoroaster, a native of Proconnesus, as living a little before the time of Osthanes. That it was this same 'Osthanes, more particularly, that inspired the Greeks, not with a fondness only, but a rage, for the art of magic, is a fact beyond all doubt: though at the same time I would remark, that in the most ancient times, and indeed almost invariably, it was in this branch of science, that was sought the highest point of celebrity and of literary renown. At all events, Pythagoras, we find, Empedocles, Democritus, and Plato, crossed the seas, in order to attain a knowledge thereof, submitting, to speak the truth, more to the evils of exile than to the mere inconveniences of travel. Returning home, it was upon the praises of this art that they expatiated — it was this that they held as one of their grandest mysteries. It was Democritus, too, who first drew attention to Apollobeches of Coptos, to Dardanus, and to Phœnix: the works of Dardanus he sought in the tomb of that personage, and his own were composed in accordance with the doctrines there found. That these doctrines should have been received by any portion of mankind, and transmitted to us by the aid of memory, is to me surprising beyond anything I can conceive. All the particulars there found are so utterly incredible, so utterly revolting, that those even who admire Democritus in other respects, are strong in their denial that these works were really written by him. Their denial, however, is in vain; for it was he, beyond all doubt, who had the greatest share in fascinating men's minds with these attractive chimeras.

There is also a marvellous coincidence, in the fact that the two arts — medicine, I mean, and magic — were developed simultaneously: medicine by the writings of Hippocrates, and magic by the works of Democritus, about the period of the Peloponnesian War, which was waged in Greece in the year of the City of Rome 300.

There is another sect, also, of adepts in the magic art, who derive their origin from Moses, Jannes, and Lotapea, Jews by birth, but many thousand years posterior to Zoroaster: and as much more recent, again, is the branch of magic cultivated in Cyprus. In the time, too, of Alexander the Great, this

profession received no small accession to its credit from the influence of a second Osthanes, who had the honour of accompanying that prince in his expeditions, and who, evidently, beyond all doubt, travelled over every part of the world.

CHAP. 3.

WHETHER MAGIC WAS EVER PRACTISED IN ITALY. AT WHAT PERIOD THE SENATE FIRST FORBADE HUMAN SACRIFICES.

It is clear that there are early traces still existing of the introduction of magic into Italy; in our laws of the Twelve Tables for instance; besides other convincing proofs, which I have already noticed in a preceding Book. At last, in the year of the City 657, Cneius Cornelius Lentulus and P. Licinius Crassus being consuls, a decree forbidding human sacrifices was passed by the senate; from which period the celebration of these horrid rites ceased in public, and, for some time, altogether.

Detailed table of contents

CHAP. 4.

THE DRUIDS OF THE GALLIC PROVINCES.

The Gallic provinces, too, were pervaded by the magic art, and that even down to a period within memory; for it was the Emperor Tiberius that put down their Druids, and all that tribe of wizards and physicians. But why make further mention of these prohibitions, with reference to an art which has now crossed the very Ocean even, and has penetrated to the void recesses of Nature? At the present day, struck with fascination, Britannia still cultivates this art, and that, with ceremonials so august, that she might almost seem to have been the first to communicate them to the people of Persia. To such a degree are nations throughout the whole world, totally different as they are and quite unknown to one another, in accord upon this one point!

Such being the fact, then, we cannot too highly appreciate the obligation that is due to the Roman people, for having put an end to those monstrous rites, in accordance with which, to murder a man was to do an act of the greatest devoutness, and to eat his flesh was to secure the highest blessings of health.

Detailed table of contents

CHAP. 5. (2.)

THE VARIOUS BRANCHES OF MAGIC.

According to what Osthanes tells us, there are numerous sorts of magic. It is practised with water, for instance, with balls, by the aid of the air, of the stars, of lamps, basins, hatchets, and numerous other appliances; means by which it engages to grant a foreknowledge of things to come, as well as converse with ghosts and spirits of the dead. All these practices, however, have been proved by the Emperor Nero, in our own day, to be so many false and chimærical illusions; entertaining as he did a passion for the magic art, unsurpassed even by his enthusiastic love for the music of the lyre, and for the songs of tragedy; so strangely did his elevation to the highest point of human fortune act upon the deep-seated vices of his mind! It was his leading desire to command the gods of heaven, and no aspiration could he conceive more noble than this. Never did person lavish more favours upon any one of the arts; and for the attainment of this, his favourite object, nothing was wanting to him, neither riches, nor power, nor aptitude at learning, and what not besides, at the expense of a suffering world.

It is a boundless, an indubitable proof, I say, of the utter falsity of this art, that such a man as Nero abandoned it; and would to heaven that he had consulted the shades below, and any other spirits as well, in order to be certified in his suspicions, rather than commissioned the denizens of stews and brothels to make those inquisitions of his [with reference to the objects of his jealousy]. For assuredly there can be no superstition, however barbarous and ferocious the rites which it sanctions, that is not more tolerant than the imaginations which he conceived, and owing to which, by a series of bloodstained crimes, our abodes were peopled with ghosts.

Detailed table of contents

CHAP. 6.

THE SUBTERFUGES PRACTISED BY THE MAGICIANS.

The magicians, too, have certain modes of evasion, as, for instance, that the gods will not obey, or even appear to, persons who have freckles upon the skin. Was this perchance the obstacle in Nero's way? As for his limbs, there was nothing deficient in them. And then, besides, he was at liberty to make choice of the days prescribed by the magic ritual: it was an easy thing for him to make choice of sheep whose colour was no other than perfectly black: and as to sacrificing human beings, there was nothing in the world that gave him greater pleasure. The Magian Tiridates was at his court, having repaired thither, in token of our triumph over Armenia, accompanied by a train which cost dear to the provinces through which it passed. For the fact was, that he was unwilling to travel by water, it being a maxim with the adepts in this art that it is improper to spit into the sea or to profane that element by any other of the evacuations that are inseparable from the infirmities of human nature. He brought with him, too, several other Magi, and went so far as to initiate the emperor in the repasts of the craft; and yet the prince, for all he had bestowed a kingdom upon the stranger, found himself unable to receive at his hands, in return, this art.

We may rest fully persuaded then, that magic is a thing detestable in itself. Frivolous and lying as it is, it still bears, however, some shadow of truth upon it; though reflected, in reality, by the practices of those who study the arts of secret poisoning, and not the pursuits of magic. Let any one picture to himself the lies of the magicians of former days, when he learns what has been stated by the grammarian Apion, a person whom I remember seeing myself when young. He tells us that the plant cynocephalia, known in Egypt as "osiritis," is useful for divination, and is a preservative against all the malpractices of magic, but that if a person takes it out of the ground entire, he will die upon the spot. He asserts, also, that he himself had raised the spirits of the dead, in order to make enquiry of Homer in reference to his native country and his parents; but he does not dare, he tells us, disclose the answer he received.

Detailed table of contents

CHAP. 7. (3.)

OPINIONS OF THE MAGICIANS RELATIVE TO THE MOLE. FIVE REMEDIES DERIVED FROM IT.

Let the following stand as a remarkable proof of the frivolous nature of the magic art. Of all animals it is the mole that the magicians admire most! a creature that has been stamped with condemnation by Nature in so many ways; doomed as it is to perpetual blindness, and adding to this darkness a life of gloom in the depths of the earth, and a state more nearly resembling that of the dead and buried. There is no animal in the entrails of which they put such implicit faith, no animal, they think, better suited for the rites of religion; so much so, indeed, that if a person swallows the heart of a mole, fresh from the body and still palpitating, he will receive the gift of divination, they assure us, and a foreknowledge of future events. Tooth-ache, they assert, may be cured by taking the tooth of a live mole, and attaching it to the body. As to other statements of theirs relative to this animal, we shall draw attention to them on the fitting occasions, and shall only add here that one of the most probable of all their assertions is, that the mole neutralizes the bite of the shrew-mouse; seeing that, as already stated, the very earth even that is found in the rut of a cart-wheel, acts as a remedy in such a case.

Detailed table of contents

CHAP. 8.

THE OTHER REMEDIES DERIVED FROM LIVING CREATURES. CLASSIFIED ACCORDING TO THE RESPECTIVE DISEASES. REMEDIES FOR TOOTH-ACHE.

But to proceed with the remedies for tooth-ache — the magicians tell us, that it may be cured by using the ashes of the head of a dog that has died in a state of madness. The head, however, must be burnt without the flesh, and the ashes injected with oil of cyprus into the ear on the side affected. For the same purpose also, the left eye-tooth of a dog is used. the gum of the affected tooth being lanced with it; one of the vertebræ also of a dragon or of an enhydriis, which is a male white serpent. The eye-tooth, too, of this last, is used for scarifying the gums; and when the pain affects the teeth of the upper jaw, they attach to the patient two of the upper teeth of the serpent, and, similarly, two of the lower ones for tooth-ache in the lower jaw. Persons who go in pursuit of the crocodile, anoint themselves with the fat of this animal. The gums are also scarified with the frontal bones of a lizard, taken from it at full moon, and not allowed to touch the ground: or else the mouth is rinsed with a decoction of dogs' teeth in wine, boiled down to one half.

Ashes of dogs' teeth, mixed with honey, are useful for difficult dentition in children, and a dentifrice is similarly prepared from them. Hollow teeth are plugged with ashes of burnt mouse-dung, or with a lizard's liver, dried. To eat a snake's heart, or to wear it, attached to the body, is considered highly efficacious. There are some among the magicians, who recommend a mouse to be eaten twice a month, as a preventive of tooth-ache. Earth-worms, boiled in oil and injected into the ear on the side affected, afford considerable relief: ashes, too, of burnt earth-worms, introduced into carious teeth, make them come out easily; and, used as a friction, they allay pains in such of the teeth as are sound: the proper way of burning them is in an earthen potsherd. They are useful, too, boiled with root of the mulberry-tree in squill vinegar, and employed as a collutory for the teeth. The small worm that is found in the plant known as Venus' bath, is remarkably useful, introduced into a hollow tooth; and as to the cabbage caterpillar, it will make hollow teeth come out, by the mere contact only. The bugs that are found upon mallows, are injected into the ears, beaten up with oil of roses.

The small grits of sand that are found in the horns of snails, introduced into hollow teeth, remove the pain instantaneously. Ashes of empty snail-shells, mixed with myrrh, are good for the gums; the ashes also of a serpent, burnt with salt in an earthen pot, and injected, with oil of roses, into the ear opposite to the side affected; or else the slough of a snake, warmed with oil and torchpine resin, and injected into either ear. Some persons add frankincense and oil of roses, a preparation which, of itself, introduced into hollow teeth, makes them come out without pain. It is all a fiction, in my opinion, to say that white snakes cast this slough about the rising of the Dog-star; for such a thing has

never been seen in Italy, and it is still more improbable that sloughing should take place at so late a period in the warmer climates. We find it stated also, that this slough, even when it has been kept for some time, mixed with wax, will extract a tooth very expeditiously, if applied thereto: a snake's tooth, also, attached to the body as an amulet, allays tooth-ache. Some persons think that it is a good remedy to catch a spider with the left hand, to beat it up with oil of roses, and then to inject it into the ear on the side affected.

The small bones of poultry, preserved in a hole in a wall, the medullary channel being left intact, will immediately cure tooth-ache, they say, if the tooth is touched or the gum scarified therewith, care being taken to throw away the bone the moment the operation is performed. A similar result is obtained by using raven's dung, wrapped in wool and attached to the body, or else sparrow's dung, warmed with oil and injected into the ear on the side affected. This last remedy, however, is productive of an intolerable itching, for which reason it is considered a better plan to rub the part with the ashes of young sparrows burnt upon twigs, mixed with vinegar for the purpose.

Detailed table of contents

CHAP. 9. (4.)

REMEDIES FOR OFFENSIVE ODOURS AND SORES OF THE MOUTH.

To impart sweetness to the breath, it is recommended to rub the teeth with ashes of burnt mouse-dung and honey: some persons are in the habit of mixing fennel root. To pick the teeth with a vulture's feather, is productive of a sour breath; but to use a porcupine's quill for that purpose, greatly strengthens the teeth. Ulcers of the tongue and lips are cured by taking a decoction of swallows, boiled in honied wine; and chapped lips are healed by using goose-grease or poultry-grease, wool-grease mixed with nut-galls, white spiders' webs, or the fine cobwebs that are found adhering to the beams of roofs. If the inside of the mouth has been scalded with any hot substance, bitches' milk will afford an immediate cure.

CHAP. 10.

REMEDIES FOR SPOTS UPON THE FACE.

Wool-grease, mixed with Corsican honey—which by the way is considered the most acrid honey of all—removes spots upon the face. Applied with oil of roses in wool, it causes scurf upon the face to disappear: some persons add butter to it. In cases of morpew, the spots are first pricked with a needle, and then rubbed with dog's gall. For livid spots and bruises on the face, the lights of a ram or sheep are cut fine and applied warm, or else pigeons' dung is used. Goose-grease or poultry-grease is a good preservative of the skin of the face. For lichens a liniment is used, made of mouse-dung in vinegar, or of the ashes of a hedge-hog mixed with oil: but, when these remedies are employed, it is recommended first to foment the face with nitre dissolved in vinegar. Maladies of the face are also removed by employing the ashes of the small, broad, snail that is so commonly found, mixed with honey. Indeed, the ashes of all snails are of an inspissative nature, and are possessed of certain calorific and deterative properties: hence it is that they form an ingredient in caustic applications, and are used in the form of a liniment for itch-scabs, leprous sores, and freckles on the face.

I find it stated that a certain kind of ant known by the name of "Herculanea," is beaten up, with the addition of a little salt, and used for the cure of these diseases. The buprestis is an insect but rarely found in Italy, and very similar to a scarabæus, with long legs. Concealed among the grass, it is very liable to be swallowed unobserved, by oxen in particular; and the moment it comes in contact with the gall, it causes such a degree of inflammation, that the animal bursts asunder; a circumstance to which the insect owes its name. Applied topically with he-goat suet, it removes lichens on the face, owing to its corrosive properties, as previously stated. A vulture's blood, beaten up with cedar resin and root of white chamæleon — a plant which we have already mentioned — and covered with a cabbage leaf, when applied, is good for the cure of leprosy; the same, too, with the legs of locusts, beaten up with he-goat suet. Pimples are treated with poultry grease, beaten up and kneaded with onions. One very useful substance for the face is honey in which the bees have died; but a sovereign detergent for that part is swans' grease, which has also the property of effacing wrinkles. Brand-marks are removed by using pigeons' dung, diluted in vinegar.

CHAP. 11.

REMEDIES FOR AFFECTIONS OF THE THROAT.

I find it stated that catarrhs oppressive to the head may be cured by the patient kissing a mule's nostrils. Affections of the uvula and pains in the fauces are alleviated by using the dung of lambs before they have begun to graze, dried in the shade. Diseases of the uvula are cured with the juices of a snail pierced with a needle; the snail, however, must be then hung up in the smoke. The same maladies are treated also with ashes of burnt swallows, mixed with honey; a preparation which is equally good for affections of the tonsillary glands. Sheep's milk, used as a gargle, alleviates diseases of the fauces and tonsillary glands. Millepedes, bruised with pigeons' dung, are taken as a gargle, with raisin wine; and they are applied, externally, with dried figs and nitre, for the purpose of soothing roughness of the fauces and catarrhs. For such cases, too, snails should be boiled unwashed, the earth only being removed, and then pounded and administered to the patient in raisin wine. Some persons are of opinion that for these purposes the snails of *Astypalæa* are the most efficacious, and they give the preference to the deterative preparation made from them. The parts affected are sometimes rubbed with a cricket, and affections of the tonsillary glands are alleviated by being rubbed with the hands of a person who has bruised a cricket.

CHAP. 12.

REMEDIES FOR QUINZY AND SCROFULA.

For quinzy we have very expeditious remedies in goose-gall, mixed with elaterium and honey, an owlet's brains, or the ashes of a burnt swallow, taken in warm water; which last remedy we owe to the poet Ovid. But of all the remedies spoken of as furnished by the swallow, one of the most efficacious is that derived from the young of the wild swallow, a bird which may be easily recognized by the peculiar conformation of its nest. By far the most effectual, however, of them all, are the young of the bank-swallow, that being the name given to the kind which builds its nest in holes on the banks of rivers. Many persons recommend the young of any kind of swallow as a food, assuring us that the person who takes it need be in no apprehension of quinzy for the whole of the ensuing year. The young of this bird are sometimes stifled and then burnt in a vessel with the blood, the ashes being administered to the patient with bread or in the drink: some, however, mix with them the ashes of a burnt weasel, in equal proportion. The same remedies are recommended also for scrofula, and they are administered for epilepsy, once a day, in drink. Swallows preserved in salt are taken for quinzy, in (loses of one drachma, in drink: the nest, too, of the bird, taken internally, is said to be a cure for the same disease.

Millepedes, it is thought, used in the form of a liniment, are peculiarly efficacious for quinzy: some persons, also, administer eleven of them, bruised in one semi-sextarius of hydromel, through a reed, they being of no use whatever if once touched by the teeth. Other remedies mentioned are, the broth of a mouse boiled with vervain, a thong of dogskin passed three times round the back, and pigeons' dung mixed with wine and oil. For the cure of rigidity of the muscles of the neck, and of opisthotony, a twig of vitex, taken from a kite's nest, is attached to the body as an amulet.

(5.) For ulcerated scrofula, a weasel's blood is employed, or the animal itself, boiled in wine; but not in cases where the tumours have been opened with the knife. It is said, too, that a weasel, eaten with the food, is productive of a similar effect; sometimes, also, it is burnt upon twigs, and the ashes are applied with axle-grease. In some instances, a green lizard is attached to the body of the patient, a fresh one being substituted at the end of thirty days. Some persons preserve the heart of this animal in a small silver vessel, as a cure for scrofula in females. Old snails, those found adhering to shrubs more particularly, are pounded with the shells on, and applied as a liniment. Asps, too, are similarly employed, reduced to ashes and mixed with bull suet; snakes' fat also, diluted with oil; and the ashes of a burnt snake, applied with oil or wax. It is a good plan also, in cases of scrofula, to eat the middle of a snake, the extremities being first removed, or to drink the ashes of the reptile,

similarly prepared and burnt in a new earthen vessel: they will be found much more efficacious, however, when the snake has been killed between the ruts made by wheels. It is recommended also, to dig up a cricket with the earth about its hole, and to apply it in the form of a liniment; to use pigeons' dung, either by itself, or with barleymeal, or oatmeal and vinegar; or else to apply the ashes of a burnt mole, mixed with honey.

Some persons apply the liver of this last animal, crumbled in the hands, due care being taken not to wash it off for three days: it is said, too, that a mole's right foot is a remedy for scrofula. Others, again, cut off the head of a mole, and after kneading it with earth thrown up by those animals, divide it into tablets, and keep it in a pewter box, for the treatment of all kinds of tumours, diseases of the neck, and the affections known as "apostemes:" in all such cases the use of swine's flesh is forbidden to the patient. "Taurus" is the name usually given to an earth-beetle, very similar to a tick in appearance, and which it derives from the diminutive horns with which it is furnished: some persons call it the "earth-louse." From the earth thrown up by these insects a liniment is prepared for scrofula and similar diseases, and for gout, the application not being washed off till the end of three days. This last remedy is effectual for a whole year, and all those other properties are attributed to it which we have mentioned when speaking of crickets. There are some, again, who make a similar use of the earth thrown up by ants; while others attach to the patient as many earth-worms as there are scrofulous tumours, the sores drying as the worms dry up.

Some persons cut off the head and tail of a viper, as already mentioned, about the rising of the Dog-star, which done, they

burn the middle, and give a pinch of the ashes in three fingers, for thrice seven days, in drink-such is the plan they use for

the cure of scrofula. Others, again, pass round the scrofulous tumours a linen thread, with which a viper has been suspended by the neck till dead. Millepedes are also used, with one fourth part of turpentine; a remedy which is equally recommended for the cure of all kinds of apostemes.

CHAP. 13.

REMEDIES FOR DISEASES OF THE SHOULDERS.

The ashes of a burnt weasel, mixed with wax, are a cure for pains in the shoulders. To prevent the arm-pits of young persons from becoming hairy, they should be well rubbed with ants' eggs. Slave-dealers also, to impede the growth of the hair in young persons near puberty, employ the blood that flows from the testes of lambs when castrated. This blood, too, applied to the arm-pits, the hairs being first pulled out, is a preventive of the rank smell of those parts.

CHAP. 14.

REMEDIES FOR PAINS IN THE VISCERA.

We give the one general name of “præcordia” to the human viscera; for pains in any part of which, a sucking whelp is applied, being pressed close to the part affected. The malady, it is said, will in such case pass into the animal; a fact which may be satisfactorily ascertained; for on disembowelling it, and sprinkling the entrails with wine, that part of the viscera will be found affected in which the patient himself was sensible of pain: to bury the animal in such a case is a point most religiously observed. The dogs, too, which we call “Melitæi,” applied to the stomach every now and then, allay pains in that region: the malady, it is supposed, passes into the animal’s body, as it gradually loses its health, and it mostly dies.

(6.) Affections of the lungs are cured by using mice, those of Africa more particularly, the animal being skinned and boiled in salt and oil, and then taken with the food. The same preparation is used also, for the cure of purulent or bloody expectorations.

Detailed table of contents

CHAP. 15.

REMEDIES FOR PAINS IN THE STOMACH.

One of the very best remedies for affections of the stomach, is to use a snail diet. They must first be left to simmer in water for some time, without touching the contents of the shell, after which, without any other addition, they must be grilled upon hot coals, and eaten with wine and garum; the snails of Africa being the best of all for the purpose. The efficacy of this remedy has been proved in numerous instances of late. Another point, too, to be observed, is to take an uneven number of them. Snails, however, have a juice, it should be remembered, which imparts to the breath an offensive smell. For patients troubled with spitting of blood, they are remarkably good, the shell being first removed, and the contents bruised and administered in water. The most esteemed kinds of all are those of Africa — those which come from Iol, in particular — of Astypalæa, and, after them, those of Ætna, in Sicily, those I mean of moderate size, for the large ones are hard, and destitute of juice. The Balearic snails, called “cavaticæ,” from being found in caverns, are much esteemed; and so, too, are those from the islands of Capreæ. Those of Greece, on the other hand, are never used for food, either old or fresh.

River snails, and those with a white shell, have a strong, rank, juice, and forest snails are by no means good for the stomach, having a laxative effect upon the bowels; the same, too, with all kinds of small snails. Sea-snails, on the other hand, are more beneficial to the stomach; but it is for pains in that region that they are found the most efficacious: the best plan, it is said, is to eat them alive, of whatever kind they may happen to be, with vinegar. In addition to these, there are the snails called “aceratæ,” with a broad shell, and found in numerous localities: of the uses to which they are put we shall speak further on the appropriate occasions. The craw of poultry, dried and sprinkled in the drink, or else used fresh and grilled, has a soothing effect upon pectoral catarrhs and coughs attended with phlegm. Snails, beaten up raw and taken in three cyathi of warm water, allay cough. A piece of dog’s skin, wrapped round any one of the fingers, affords relief to patients suffering from catarrh. A broth made of boiled partridges is strengthening for the stomach.

CHAP. 16.

REMEDIES FOR PAINS IN THE LIVER, AND FOR SPITTING OF BLOOD.

For the cure of pains in the liver, a wild weasel is taken with the food, or the liver only of that animal; a ferret also, roasted like a sucking-pig. In cases of asthma, millepedes are used, thrice seven of them being soaked in Attic honey, and taken internally by the aid of a reed: for all vessels, it should be remembered, turn black on coming in contact with them. Some persons grill one sextarius of these insects on a flat pan, till they become white, and then mix them with honey. There are some authorities who call this insect a “centipede,” and recommend it to be given in warm water. Snails are administered to persons subject to fainting fits, alienation of the senses, and vertigo: for which purposes, a snail is beaten up, shell and all, with three cyathi of raisin wine, and the mixture is administered warm with the drink, for nine days at most. Others, again, give one snail the first day, two the second, three the third, two the fourth, and one the fifth; a mode of treatment also adopted for the cure of asthma and of abscesses.

There is, according to some authorities, an insect resembling the locust in appearance, destitute of wings, and known by the Greek name of “troxallis,” it being without a name in Latin: a considerable number of writers, however, consider it as identical with the insect known to us as “gryllus.” Twenty of these insects, they say, should be grilled, and taken in honied wine, by patients troubled with hardness of breathing or spitting of blood. Some persons pour pure grape-juice, or sea-water, upon unwashed snails, and then boil and eat them for food; or else they bruise the snails, shells and all, and take them with this grape-juice. A similar method is also adopted for the cure of cough. Honey in which the bees have died, is particularly good for the cure of abscesses. For spitting of blood a vulture’s lungs are used, burnt upon vine logs, and mixed with half the quantity of pomegranate blossoms, or with the same proportion of quince and lily blossom: the whole being taken morning and evening, in wine, if there is no fever; but where there are symptoms of fever, instead of wine, water is used in which quinces have been boiled.

CHAP. 17.

REMEDIES FOR AFFECTIONS OF THE SPLEEN.

According to the prescriptions given by the magicians, a fresh sheep's milt is the best application for pains in the spleen, the person who applies it uttering these words: "This I do for the cure of the spleen." This done, it is enjoined that the milt should be covered up with mortar in the wall of the patient's sleeping-room, and sealed with a ring, a charm being repeated thrice nine times. A dog's milt, removed from the animal while still alive, taken with the food, is a cure for diseases of the spleen: some, again, attach it fresh to that part of the patient's body. Others give the patient — without his knowing it — the milt of a puppy two days old, to eat, in squill vinegar; the milt, too, of a hedge-hog is similarly used. Ashes of burnt snails are employed, in combination with linseed, nettle-seed, and honey, the treatment being persisted in till the patient is thoroughly cured.

A green lizard has a remedial effect, suspended alive in an earthen vessel, at the entrance of the sleeping-room of the patient, who, every time he enters or leaves it, must take care to touch it with his hand: the head, too, of a horned owl, reduced to ashes and incorporated with an unguent; honey, also, in which the bees have died; and spiders, the one known as the "lycos" in particular.

[Detailed table of contents](#)

CHAP. 18.

REMEDIES FOR PAINS IN THE SIDE AND IN THE LOINS.

For pains in the side, the heart of a hoopoe is highly esteemed; ashes, too, of burnt snails, that have been boiled in a ptisan, snails being sometimes applied in the form of a liniment, alone. Potions employed for this purpose have a sprinkling in them of the ashes of a mad dog's skull. For the cure of lumbago, the spotted lizard from beyond seas is used: the head and intestines being first removed, the body is boiled in wine, with half a denarius of black poppy, and the decoction is taken in drink. Green lizards, also, are taken with the food, the feet and head being first removed; or else three snails are crushed, shells and all, and boiled with fifteen peppercorns in wine. The feet of an eagle are wrenched off in a contrary direction to the joint, and the right foot is attached to the right side, the left foot to the left, according as the pains are situate. The miilepede, which we have spoken of as being called the "oniscos," is a cure for these pains, taken, in doses of one denarius, in two cyathi of wine. The magicians recommend an earth-worm to be put in a wooden dish, which has been split and mended with iron wire; which done, some water must be taken up with the dish, the worm drenched with it and buried in the spot from which it was taken, and the water drunk from the dish. They assert, also, that this is a marvellously excellent cure for sciatica.

Detailed table of contents

CHAP. 19. (7.)

REMEDIES FOR DYSENTERY.

Dysentery is cured by taking the broth of a leg of mutton, boiled with linseed in water; by eating old ewe-milk cheese; or by taking mutton suet boiled in astringent wine. This last is good, too, for the iliac passion, and for inveterate coughs. Dysentery is removed also, by taking a spotted lizard from beyond seas, boiled down till the skin only is left, the head, feet, and intestines, being first removed. A couple of snails also, and an egg, are beaten up, shells and all, in both cases, and made lukewarm in a new vessel, with some salt, three cyathi of water, and two cyathi of raisin-wine or date-juice, the decoction being taken in drink. Ashes, too, of burnt snails, are very serviceable, taken in wine with a modicum of resin.
